Keywords: Hybrid 2-Population GA. Genetic algorithm. Job shop scheduling. IAGA. SAGA

Abstract. In this paper, an analysis of a hybrid two-population genetic algorithm (H2PGA) for the job shop scheduling problem is presented. H2PGA is composed of two populations that constitute of similar fit chromosomes. These two branches implement genetic operation separately using different evolutionary strategy and exchange excellent chromosomes using migration strategy which is acquired by experiments. Improved adaptive genetic algorithm (IAGA) and simulated annealing genetic algorithm (SAGA) are applied in two branches respectively. By integrating the advantages of two techniques, this algorithm has comparatively solved the two major problems with genetic algorithm which are low convergence velocity and potentially to be plunged into local optimum. Experimental results show that the H2PGA outperforms the other three methods for it has higher convergence velocity and higher efficiency.

Introduction

To achieve GAs potential, genetic algorithms can take advantage of parallel computing environments based on their well parallelizable nature [1-3]. On the base of study on many kinds of improved algorithms, a novel H2PGA composed of IAGA and SAGA[4-5] is presented. There are two parallel populations evolving synchronously in this algorithm by way of enhancing optimizing efficiency. IAGA is applied in one population, convergence process can be fast; in the other population SAGA is used so partial searching can be more efficient. This H2PGA, which integrates the advantages of IAGA and SAGA, makes it possible to avoid falling into local optimum, so its convergence velocity and efficiency could become higher. Benchmark LA01 (10×5) job-shop scheduling problem are used to show the effectiveness of the proposed method. Experimental results demonstrate that the proposed genetic algorithm does not get stuck at local optima easily, and it is fast in convergence.

Hybrid 2-Population Genetic Algorithm

Design of H2PGA. This hybrid 2-population genetic algorithm belongs to category of Parallel Genetic Algorithm (PGA) which has parallel framework working on single processor, so that it has high efficiency and little processing time.

In view of shortcoming that genetic algorithm is prone to be trapped into local optimum; H2PGA initializes two populations that constitute of similar fit chromosomes during the phase of initialization. These two populations have a parallel relationship and implement reproduction respectively using different evolutionary strategy. These two population exchange several chromosomes which have high fitness after a number of iterations by way of excellent foreign individuals. These migrated chromosomes can enhance fitness and improve individual variety of each population. Thereby this new method can avoid falling into local optimum. The framework of H2PGA is shown in Fig.1. The example of how the initial population is divided into two parallel populations is shown in Fig.2. Each number in the table signifies the supposed fitness of corresponding chromosome.

The operation of H2PGA can be divided into five stages as follows:

1) Generate initial random population of solutions.

2) Evaluate the fitness of the initial chromosomes and divide the population into two populations averagely.

3) Implement reproduction separately in both of the populations using IAGA and SAGA evolutionary strategy.

4) If migration condition is fulfilled, exchange definite chromosomes from IAGA and SAGA population to each other.

5) Go to (3) or exit if convergence or run time constraints have been met.

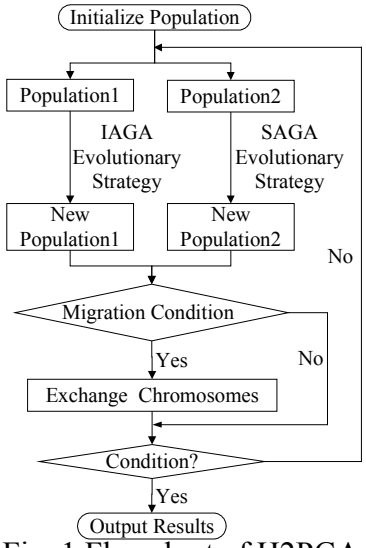

Fig. 1 Flowchart of H2PGA

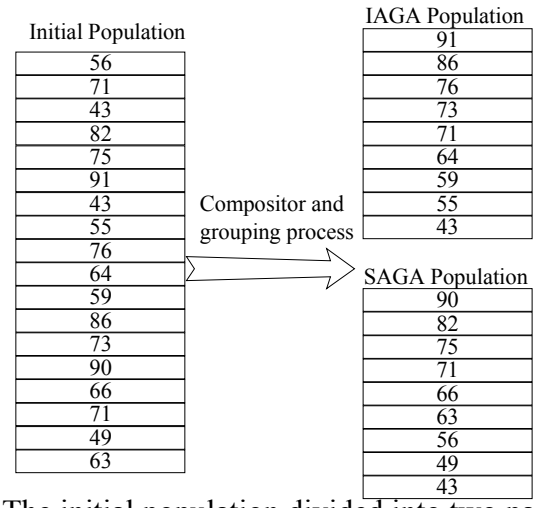

Fig. 2 The initial population divided into two parallel populations

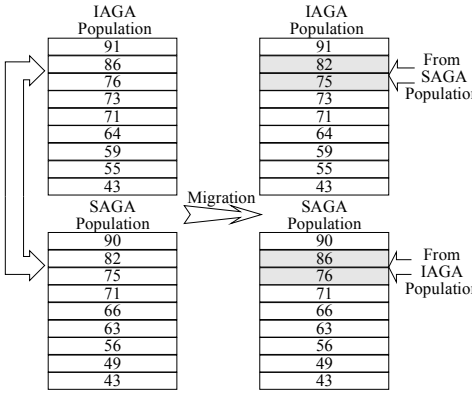

Fig. 3 Exchange chromosomes between the two populations.

Fig. 4. Chromosome design

IAGA is applied in one population making the crossover and mutation probability adjusted adaptively and nonlinearly, that can avoid such disadvantages as premature convergence, low convergence speed and low stability. SAGA is applied in another population utilizing its merit of the strong ability of partial search.

The new method has parallel optimizing framework and holistic control. IAGA and SAGA embranchment carry out optimizing like crossover and mutation process respectively. These two populations would exchange several chromosomes which have high fitness if migration condition is fulfilled. An example of how chromosomes are exchanged between two populations is shown in Fig.3.

Migration Strategy

The frequency and the number of migrations are two important parameters which have to be taken into account when migrating chromosomes between two populations.

Migration Frequency *f*: It describes the interval between the points in which excellent chromosomes from one population can be transferred to another. It is expressed as a number of generations between two migration points. If the value of *f* is too low, when one branch is trapped into partial optimization, the other one would also tend to be trapped; if the value of *f* is too high, the expected mutual role in promoting between two populations can not be achieved effectively.

Migration Number *T*: The number of chromosomes migrated between two populations each time. If migration number is too large, chromosomes in both populations would tend to the same and trapping into partial optimization is potential; if migration number is too small, optimizing efficiency would reduce.

Experiments are carried out to work out the best value of Migration Frequency *f* and Migration Number *T* toward a typical job-shop scheduling problem LA01. Experimental results show that the average number of iterations is smaller where migration frequency *f*=5, migration number *T*=2. Experimental results are shown in Table 1 which exhibit average numbers of iterations under different conditions. Each data is obtained by ten times experiments.

Chromosome design

A chromosome has gene information for solving the problem for genetic algorithm. At present, the encoding method often used to solve the scheduling problem is the operation-based representation encoding which is applied in H2PGA. This representation encodes a schedule as a sequence of operations and each gene stands for only one operation. The chromosome shows the order of job-number. An example of a chromosome for a 3×3 job-shop scheduling problem is shown in Fig.4.

Table 1 Experiments for average numbers of iterations under different conditions

f \ *T*	1	2	3	4	5	*6*
1	12.3	13.1	14.5	14.6	13.2	13.5
2	14.1	13.2	15.0	14.1	14.3	14.1
3	12.2	8.6	14.7	14.5	14.5	15.2
4	11.5	8.7	12.5	14.0	13.1	14.2
5	8.6	7.2	12.4	13.4	13.2	14.3
6	11.6	11.4	13.0	13.0	13.1	13.5
7	12.3	11.6	9.1	10.3	10.1	14.1
8	14.0	12.7	9.8	9.2	12.1	12.8
9	14.1	12.5	13.4	13.6	13.2	12.4
10	14.8	11.9	14.0	14.3	14.6	13.0

Experiments and results analysis

The performance of the H2PGA is compared to the other three methods that include of a single population GA (SGA), IAGA and SAGA. It is evaluated using a standard problem LA01 which is designed by Lawrence in 1984. The capacity of LA01 is 10×5 means that there are 10 jobs and 5 machines need to be ordered.

Table 2 Parameters of H2PGA for LA01

population	Evolution time	*Pc1*	*Pc*2	*Pm1*
100	35	0.9	0.6	0.1
Pm2	Crossover time	Mutation time	Initial temperature	Attenuation coefficient
0.005	50	50	1000	0.9

The parameters of H2PGA in Table 2 are acquired by experiences. P_c1 is crossover probability in IAGA population, P_c2 is crossover probability in SAGA population, P_m1 is mutation probability in IAGA population, P_m2 is mutation probability in SAGA population. The programming language is Visual Studio C#.NET, and it runs on Windows XP with Intel Core 2 E7400.

The experimental results in Table3 show that H2PGA has higher convergence speed and higher convergence probability by comparison between four different methods. The H2PGA convergent curves of LA01 shown in Figures 5 are very stable. So the improved genetic algorithm has the characteristics of high convergence speed and excellent searching ability.

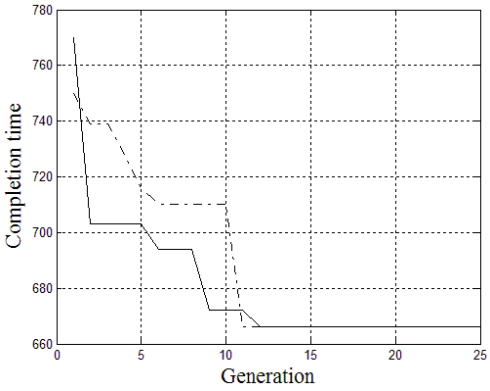

Fig. 5 The H2PGA convergent curves of LA01

Table 3 Experimental results

	IAGA	SAGA	SGA	H2PGA
Average Time/s	27.7	30.8	31.5	22.7
Average Iterative Time	14.7	13.9	15.7	11.4
Minimum Convergence Time/s	9	8	10	5
Minimum Iterative Time	5	8	7	4
Convergence probability	0.4	0.4	0.3	0.6

Conclusion

In this paper we have presented a hybrid two-population genetic algorithm scheme for the job-shop scheduling problem. The initial population is divided into two branches using IAGA and SAGA strategy which have been introduced. The proposed scheme aims to synthesize parallel framework with hybrid algorithm to improve the ability for using genetic algorithm to solve the job scheduling problems. Experimental results show that the suggested method is capable of producing competitive performance compared to the other three kind of genetic algorithms.

However, our H2PGA is more complicated than the standard genetic algorithm, and it also has more tunable parameters. It is hard to find out the best parameter which can impact the capability of algorithm seriously. Therefore, this kind of parallel and hybrid genetic algorithms still have many aspects to be improved.

Keywords: Principal component analysis, Non-parametric statistics, Pollution rate, Correlation coefficient

Abstract. Principal component analysis algorithm is widely applied in solving a large number of dimension reduction problems for high-dimensional data in fields such as image identification and comprehensive evaluation due to its clear conception and simple application. The PCA based on covariance matrix and correlation coefficient matrix is very sensitive to abnormal values so that the data structure is distorted. As a result, there exist great deviations in the analysis results and it is hard to explain. The traditional PCA is remade in this paper based on non-parametric statistical ideas, nonparametric correlation coefficient and gray relational coefficient, in order to define three kinds of robustness evaluation criteria and objectively evaluate the robustness of the algorithm through numerical experiments. The results of the numerical experiments show that the new algorithm is of good robustness to noise pollution and the algorithm is of good applicability.

Introduction

Covariance matrix and correlation coefficient matrix are extremely important in multivariate statistical analysis. However, neither the covariance matrix nor the correlation coefficient matrix is a robust estimator. They are extremely sensitive to abnormal values so that both eigenvalues and eigenvectors are influenced. In data analysis, one or several abnormal values can make the data structure distorted. Campbell calculated the eigenvalues and eigenvectors by the covariance matrix after robustness. The disadvantage is that the calculated amount of the covariance matrix is large and it is not appropriate to be adopted in large samples [1]. Based on the non-parametric statistical theory with good robustness, a principal component analysis algorithm based on non-parametric correlation coefficient is proposed in this paper.

Non-parameter correlation coefficient

Non-parametric statistical method is a statistical method neither dependent on population distribution and its parameters nor constrained by the distribution. Compared with parametric statistical methods, non-parametric statistical methods have the features of wide application and good robustness. Non-parametric statistical methods have few restrictions on overall modes. The estimation will not be greatly influenced when the overall model is slightly changed. A random sample from an unknown distribution can be studied with the method of goodness-of-fit test in non-parametric statistics, to check whether the unknown distribution function agrees with the null hypothesis being a known and concrete distribution [2]. Non-parametric correlation coefficients with robustness are selected in this paper and the liner correlation coefficients short of robustness are replaced by gray correlation coefficients to form the robust correlation coefficient matrix[3].

Suppose (x_1, x_2, …, x_n) to be a group of sample observations of the overall matrix X. Then arrange them in the order from small to large $x_1^* \le x_2^* \le \ldots \le x_n^*$. After the arrangement, $x_i = x_R^*$. Then, R is called the order of x_i. The common non-parametric correlation coefficients include Spearman correlation coefficient and Kendall τ correlation coefficient.

Spearman order correlation coefficient. R_i represents the order of X_i in sample X and Q_i represents the order of Y_i in sample Y. Then the Spearman order correlation coefficient is defined as r_s:

$$r_S = 1 - \frac{6}{n(n^2-1)} \sum_{i=1}^{n} (R_i - Q_i)^2 \tag{1}$$

Kendall τ correlation coefficient. Kendall proposed another correlation testing method to test whether the two variables are correlated by judging whether they are consistent with each other. The pairs (X_i, Y_i) and (X_j, Y_j) are consistent or their directions in variation are consistent. Kendall τ correlation coefficient can be defined [4]:

$$\tau = \frac{2}{n(n-1)} \sum_{1 \le i \le j \le n} \operatorname{sign}((X_i - X_j)(Y_i - Y_j)) \tag{3}$$

Where, $$\operatorname{sign}((X_i - X_j)(Y_i - Y_j)) = \begin{cases} 1, (X_i - X_j)(Y_i - Y_j) > 0 \\ 0, (X_i - X_j)(Y_i - Y_j) = 0 \\ -1, (X_i - X_j)(Y_i - Y_j) < 0 \end{cases}$$

The value of τ calculated with formula (3) shall be tested in the Kendall τ statistics table.

Gray correlation coefficient. Take the series after nondimensionalize $X_0 = \{x_{01}, x_{02} \cdots, x_{0n}\}$ as the standard series and the compared series is $X_i = \{x_{i1}, x_{i2} \cdots, x_{in}\}$ （$i = 1,2,3 \ldots m$）, the formula to calculate the correlation coefficient ξ_{ik} is given under:

$$\xi_{0i} = \frac{\min\limits_i \min\limits_k |X_{ik} - X_{0k}| + \rho \max\limits_i \max\limits_k |X_{ik} - X_{0k}|}{|X_{ik} - X_{0k}| + \rho \max\limits_i \max\limits_k |X_{ik} - X_{0k}|} \quad （i = 1,2,3 \ldots m, k = 1,2,3 \ldots n）$$

The range of resolution ratio is (0, 1). In order to guarantee a good resolution effect, ρ is generally taken as 0.5. Solve the gray correlation coefficient ξ_{ij} between X_i and X_j. Then the gray correlation coefficient matrix can be obtained.

Numerical experiments

Take n-dimensional normal distribution matrix $\boldsymbol{X} \sim \boldsymbol{N}$（$\boldsymbol{\mu}$，$\boldsymbol{\Sigma}$）as ($m$-$m\varepsilon$)×$n$ dimensional primary sample to generate n-dimensional normal distribution $\boldsymbol{Y} \sim \boldsymbol{N}$（$\alpha\mu$，$\beta\Sigma$）as $m\varepsilon \times n$ dimensional noise sample. In this example, take n=10，m=100，α=2，β=5，μ=[0.81, 0.91, 0.12, 0.91, 0.63, 0.098, 0.28, 0.55, 0.96, 0.96]，$\Sigma = I_{10\times 10}$ and define $\boldsymbol{XY}$=[$\boldsymbol{X}$, $\boldsymbol{Y}$] as the sample matrix to be analyzed [5]. As for the i^{th} kind of correlation coefficient matrix, the correlation coefficient matrix is written as R_ε^i when the pollution rate is ε. The principal eigenvalue is λ_ε^i and the principal eigenvector is $\boldsymbol{V}_{\varepsilon,k}^i$. k is the component of vector $\boldsymbol{V}$（k=1, 2,… , n）. The algorithm robustness evaluation criterions defined in this paper are as shown in formula (4), formula (5) and formula (6). The robustness of several correlation coefficient matrixes is hereby compared.

F norm criterion： $$F_\varepsilon^i = \frac{\left\| R_\varepsilon^i \right\|_F}{\left\| R_{\varepsilon=0}^i \right\|_F} \tag{4}$$

Principal eigenvalue criterion： $$L_\varepsilon^i = \frac{\lambda_\varepsilon^i}{\lambda_{\varepsilon=0}^i} \tag{5}$$

Principal eigenvector criterion: $v_{\varepsilon}^{i}=\frac{1}{n}\sum_{k=1}^{n}\left|\frac{\boldsymbol{V}_{\varepsilon,k}^{i}-\boldsymbol{V}_{\varepsilon=0,k}^{i}}{\boldsymbol{V}_{\varepsilon=0,k}^{i}}\right|$ (6)

The correlation coefficient matrixes are influenced by pollution rate so that the calculation values of the three criteria are fluctuated. The degree of fluctuation can be represented by variable coefficient, as shown in Table 1. The fluctuation conditions are as shown in Fig.1, Fig.2 and Fig.3. Numerical experiment shows that the fluctuations of gray correlation coefficient matrix are the smallest. It indicates that the correlation matrix generated from gray correlation coefficient has better robustness. Therefore, PCA with better robustness, gray principal component analysis (GPCA), can be obtained. The traditional linear correlation coefficient matrix is replaced by a gray correlation coefficient matrix to generate gray principal components at all levels.

Summary

Based on non-parametric statistical idea and non-parametric correlation coefficient and gray correlation coefficient, traditional principal analysis algorithm is remade to objectively evaluate the robustness of the algorithm by numerical experiments. The results of numerical experiments show that the new algorithm is of good robustness to noise pollution and the algorithm is of good applicability.

Table 1 Variable coefficient of the fluctuation deviation

	Pearson	Spearman	Kendall	Gray correlation

Keywords: Interpolation; Design; Zadoff-Chu Sequence; Model

Abstract. HF channel sounding requires perfect autocorrelation property of the sounding sequences. Compared with other pseudonoise sounding sequences, Zadoff-Chu sequence gets great attention due to its predominant periodic autocorrelation property. In order to adapt the spectrum property of Zadoff-Chu sequence to the requirement of HF channel sounding transmitter-receiver, the Formula Direct Interpolation Algorithm (FDIA) is put forward by which the amplitude frequency characteristic of Zadoff-Chu sequence can be enhanced. Application examples show that, this system can significantly improve the efficiency of aerodynamic design.

Introduction

HF channel sounding serves frequency forecast and management of HF communication and is significant in the establishment of reliable HF communication. The selection or design of sequences is a key technique in HF channel oblique sounding. At present, the pseudo-noise sequences used as sounding sequences in traditional pulse compression channel sounding system for correlation detection are periodic maximal length sequence (viz. m sequence), Barker code, etc., of which the performance is assessed by their auto-correlation properties. In recent years, Constant Amplitude Zero Auto-correlation (CAZAC) sequences get great attention and are applied to many fields due to their perfect periodic autocorrelation properties. At present, the maximal length of Barker code is thirteen which is too short and limits its application[1]. Even though the periodic auto-correlation property of m sequence is good, it is still in the shade compared with the periodic auto-correlation property of CAZAC sequences. The Zadoff-Chu sequence studied in the paper is one of CAZAC sequences, of which the periodic auto-correlation function (PACF) theoretically is zero for all nonzero lags[2].

Currently, with the growing demand for development of space resources and increasingly fierce competition of commercial satellite launch market, the next generation launcher with high-performance and low-cost is becoming research focus in many countries. Modular design is considered to be the future direction of launch vehicle. It decomposes the launcher into several standard modules. By combing different modules, various capabilities launch vehicle would be assembled to meet different payload requirements[3]. Therefore, the development cycle will be significantly shortened, the costs will be lower, and reliability will be enhanced. Aerodynamic performance of launch vehicle mainly depends on their shape exposed to the air. It also affects other characteristics of launch vehicle, such as trajectory, flight stability, mechanical properties, etc. R&D of Launch vehicle is facing combinatorial explosion problem caused by modular design. That is to say, the possible number of launch vehicle is much more than the number of modules[4].

Decimation Method of Sequence Interpolated by FDIA

In HF channel sounding, the decimation of the signal which has been processed by band pass filter, down conversion and low pass filter is necessary at the receiver. However, the decimation becomes complicated due to the delay in the channel. Besides, the values of Zadoff-Chu sequence interpolated by FDIA don't have perfect periodic auto-correlation property except the values

maintained from the original Zadoff-Chu sequence. As a result, several times of decimations are needed to seek the optimal decimation position after the approximate jumping-off point of the received sequence is found out. Decimation is done once after a bit shift every time.

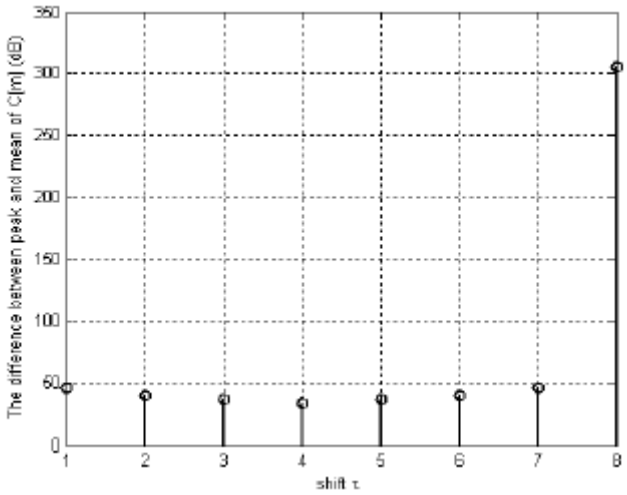

Fig.1 Relation of differences between peaks and means of [m] C and the shift τ

Motion Control Section

Fig.2 shows the spectra of Zadoff-Chu sequence respectively interpolated by FDIA and commonly used interpolation algorithm with L=1024 and k=1. From the figure we can see that although the spectrum of the sequence interpolated by the commonly used interpolation algorithm is compressed, it has many big side-lobes and rolls off slow. And that the spectrum of the sequence interpolated by FDIA is almost no big side-lobes and rolls off fast. So the sequence energy is centralized, which make it satisfy the bandwidth requirement of HF channel sounding transmitter-receiver.

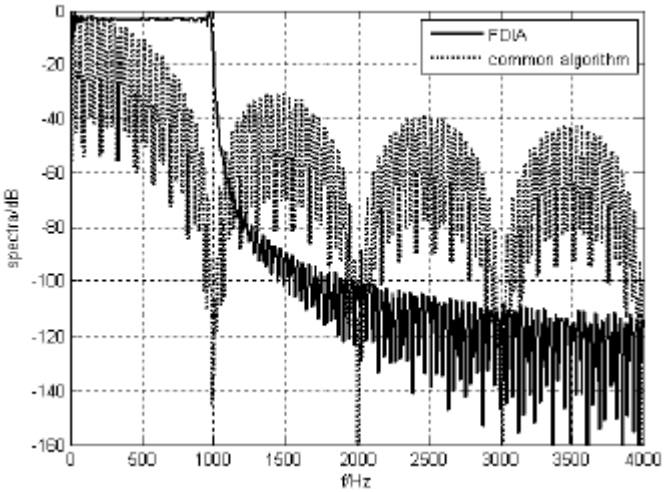

Fig.2 Spectra of sequences respectively inserted by FDIA and commonly used interpolation algorithm

Movement control card can receive PC control instruction, and the axes interface to be controlled send pulses to relevant servo controller to control motor rotation angle, and then ball-screw will convert rotation angle to horizontal displacement, so as to carry the infrared supply horizontal or vertical movement. The control part mainly includes movement control card, servo controller and so on, motor control command is sent through the PC software to regular the movement control card to produce the corresponding output pulse. The whole movement process need two axes motor control respectively, it is adequate for us to use the movement control card supported four axes, and available for circular interpolation, continuous linear interpolation, so the card can meet the equipment requirements. Actuator is a key part of the whole system, which is designed three-rail

plane, including two horizontal rails and one vertical rail, ball-screw inside, which can drive the slider with infrared light supply to move in the whole plane. There at the edge of rail separately installs limit switch and origin switch to determine the origin and the maximum boundary.

System Software Design

PC software is developed with VC++6.0 that of good interactive interface, enable the system to control in realtime. In motor control section, through the user interface the user can undertake POST (power on self test), path planning, track planning path and so on. The program flow diagram shows as Fig.3. The user can arrange what to do, and how to do because of VC++6.0 based on events programming, with response of events set through good interface, such as when clicked on a button, then the program execute button operation responded.

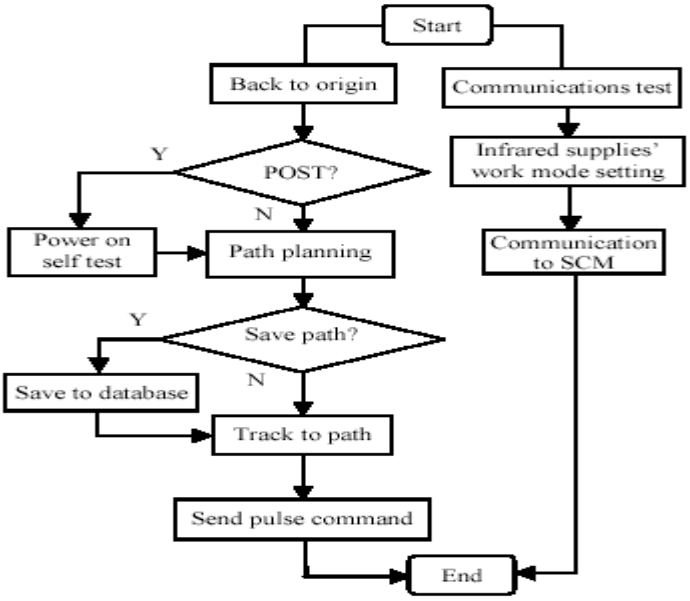

Fig.3 Programm flow diagram

When the program is running, the first to do is initialization, upper computer software communicates with single-chip microcomputer firstly to determine whether it works properly, which can be shown in the user-interface, at the same time moving infrared light supply under control is carried by slider back into origin to ensure the whole motion correction; Then the user can select POST which can track a predetermined path to check whether the system is working normally. Users can draw route planning with the existing lines, rectangular, circle planning in the picture box of software, after successful design software can save track data in a database, and infrared supply can track the path also in directly. The software can support user-defined trajectory, user select multiple points to draw path planning, which can draw any graphics.

Conclusion

In HF channel oblique sounding, the selection or design of sounding sequences is a key technique. The paper investigates the periodic autocorrelation property of Zadoff-Chu sequence based on the introduction of the definition and properties of CAZAC sequences. Aiming at resolving the problem that the spectrum of Zadoff-Chu sequence is not band-limited which makes it be not suitable for transmission in HF channel, the FDIA is proposed in the paper by which the amplitude frequency characteristic of Zadoff-Chu sequence can be enhanced. The comparisons of the spectra, the real parts and the imaginary parts of the sequences respectively interpolated by FDIA and commonly used interpolation algorithm are carried out. At the same time, an effective method of achieving optimal decimation of the Zadoff-Chu sequence interpolated by FDIA is provided. In the control process, it is convenient to process all necessary parameter setting and adjustment, and in the control process of the whole system shows superior performance and achieves the expected effect.

Keywords: Algorithm; Mutation; Swarm Intelligence; Structure

Abstract. In order to resolve these problems, we put forward a new design of the intelligent lock which is mainly based on the technology of wireless sensor network. Particle swarm optimization (PSO) is a recently proposed intelligent algorithm which is motivated by swarm intelligence. PSO has been shown to perform well on many benchmark and real-world optimization problems; it easily falls into local optima when solving complex multimodal problems. To avoid the local optimization, the algorithm renews population and enhances the diversity of population by using density calculation of immune theory and adjusting new chaos sequence. The paper gives the circuit diagram of the hardware components based on single chip and describe how to design the software. The experimental results show that the immune genetic algorithm based on chaos theory can search the result of the optimization and evidently improve the convergent speed and astringency.

Introduction

The electric equipments formerly operated mainly by manual operation gradually have been replaced by remote operation, and the mode of single substations has gradually changed to the mode of centralized control substations. Particle swarm optimization (PSO) is a new intelligent algorithm which was firstly developed by Kennedy and Eberhart in 1995. Like other evolutionary algorithms (EAs), PSO is also based on population search, but it differs from EA in iterative operations. In a general EA, it usually contains three operations, crossover, mutation and selection, while PSO does not have any such kinds of operations. In PSO, it only has two operations, velocity and position updating equations. In EAs, the crossover is helpful to inherit excellent features from parents, and the mutation is beneficial for improving the diversity of swarm. To keep these good operations, some researchers embedded these operators into PSO and obtained good performance. For example, Wang et al. proposed a novel multi-parent crossover operator, in which an offspring is generated by recombination of the current particle and another three random particles. Simulation studies on six multimodal optimization problems show that the proposed MPSO achieves better results than standard PSO and classical evolutionary programming (CEP). Besides of the crossover, some mutation techniques are also introduced to PSO. Coelho and Krohling proposed a modified PSO algorithm based on Cauchy and Gaussian distribution, in which the Gaussian and Cauchy probability distribution to update the velocity of PSO. Higashi and Iba embedded a Gaussian mutation operator into PSO. Wang et al. proposed an adaptive Cauchy mutation in PSO, and this mutation technique has been applied to other PSO algorithms. Stacey used a Cauchy mutation for each dimension of position with probability 1/D, where D is the number of dimension. Under these situations designing a reasonable on-line computer anti-lock system is an alternative to solve the current problem[1].

In this paper, we also propose a new mutation operator in PSO. The proposed mutation strategy combines the search information of the global best particle and another two random particles. To test the performance of our algorithms, there are about ten well-known benchmark problems used in the experiments. Experimental results show that our approach obtains promising results and outperforms PSO. The rest paper is organized as follows. This paper presents an improved chaos immune genetic algorithm. The algorithm initializes initial population by using the chaos, and it has

the good solution on the beginning of iteration and reduces the diversity of population on the later period of iteration. Because the immune body density is introduced, when the density is lower than the threshold value, the partial antibodies which are produced by using the insect mouth equation can substitute the evolution population's partial antibodies, thus, the local optimization was avoided[2]. After the overlapping and mutation has ended, the algorithm sorts to adaptive value of the new population, and it locally optimizes the biggest adaptive value by using chaos theory, thus, it enhances the precision of the solution and improves the searching speed. When we respectively make the test by the unvaried multi-peak values and the multi-Vidor peak value function, we have the good effect.

Wireless sensor network consists of the joints of the cheap micro-sensors deployed in the monitoring area, which forms a multi-hop and self-organizing network by means of wireless communication[3]. The network is data-centered and task-based, in which the joints distinguish with each other by serial numbers. When customers inquire about events with access to the network, they can directly notice their events of interest to the network instead of noticing to some joint with definite serial number. General topology structure of wireless sensor networks mainly adopts cluster structure or tree structure with center existing. This article puts forward an intelligent lock design based on wireless sensor network for on-line computer five-anti-lock system based field bus and wireless sensor network. The intelligent lock can let the on-line mechanical handling sector lock and let electrical equipments such as breakers and electric knife gate valves lock by remote operation[4]. It also instantaneously collects equipment status and charged situations so that the five-anti mainframe can on-line track, check, and control the operation situations of the intelligent lock.

Software Design of Intelligent Lock

The wireless sensor modules adopt the independent single chips to control the FR chips, so under the terms of the agreement are met, the software designing mainly consider how to establish the physical link between the intelligent locks as well as between the intelligent locks and on-line computer keys. The wireless transmission of control data and the specific control and inspection operations of the intelligent locks are solved by the application layer software. The software framework of the intelligent locks is shown as Fig.1.

Firstly, the on-line computer key scans for empty information channels to try to establish a new network. Once some empty information channel is found, it will select a random personal area network and start to monitor the channel; now the network is established.

Afterwards, if another on-line computer key broadcasts frames in the same channel, the former on-line computer key will response and state its existence. Next, when the intelligent lock is on power, it will scan all of the available information channels to search for on-line computer key and try to join the network. The on-line computer key will decide whether to let the intelligent lock to join the local network through the value of the intelligent lock.

Once the intelligent lock joins some network, it will save the network information; when starting next time, it will rejoin the network automatically. After the success of joining the network, the intelligent will enter the resting state in order to save energy.

If some operation is to be conducted, the on-line computer key will keep the data frames in indirect-sending buffer until the intelligent lock inquires or is timeout. The intelligent lock will be waken-up periodically and send the inquiry request to the on-line computer key, which will search the indirect-sending buffer. If one frame is found to wait to send to the joint, the on-line computer key will send the frame and wait for confirmation.

Once the frame is confirmed, the on-line computer key will delete the frame from the indirect-sending buffer.

Algorithm flow chart is shown as Fig.2.

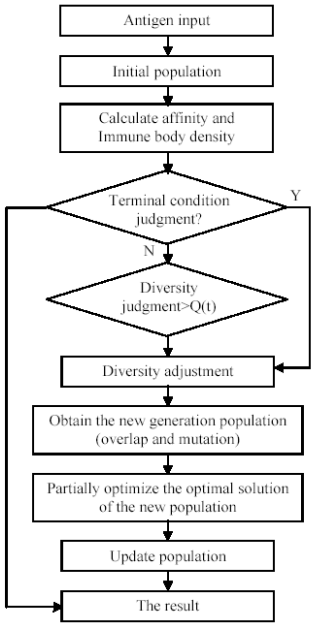

Fig.2 Algorithm flow chart

Simulation

Simulation results are shown as Fig.3.

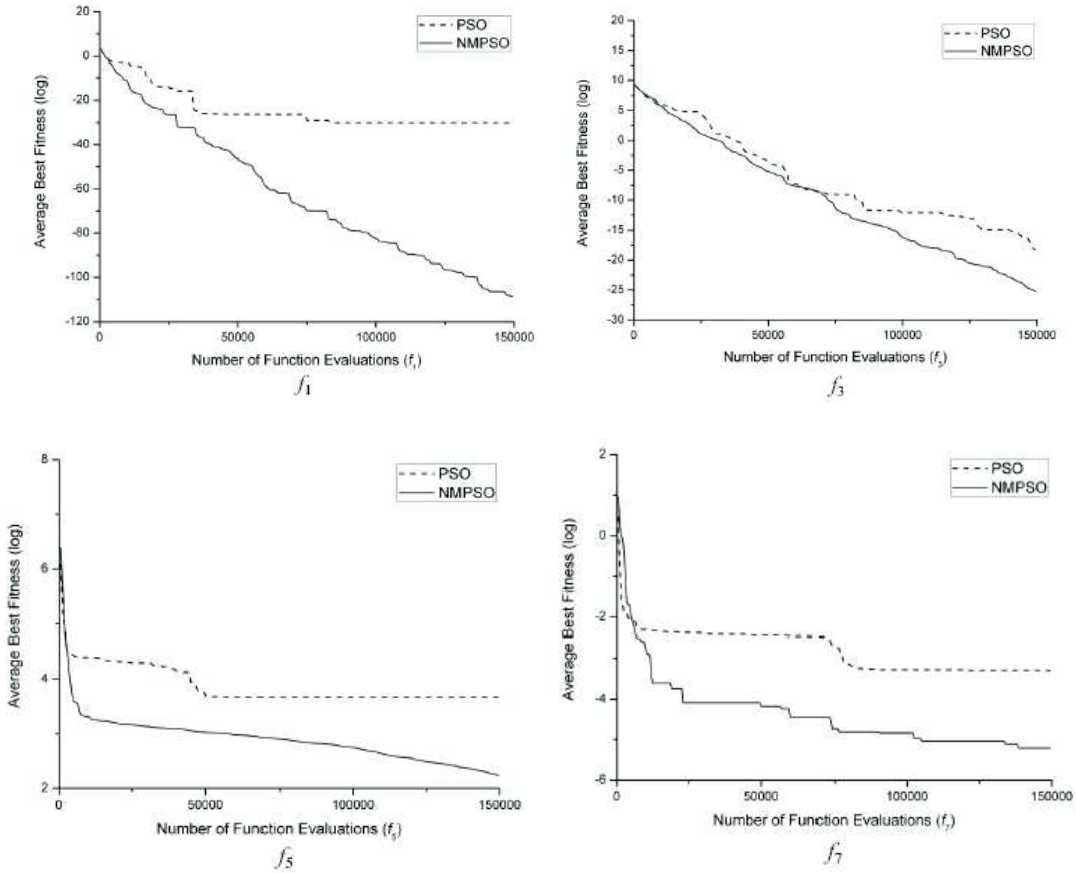

Fig.3 Evolutionary curves of standard PSO and NMPSO on four problems

Conclusion

This paper presents an improved PSO algorithm to enhance the performance of standard PSO. The proposed approach is called NMPSO, which embeds a novel mutation by incorporating with

the search information of the global best particle and other two random particles. It is to hope this improvement can help trapped particles jump to better positions. Simulation results on ten problems show that NMPSO not only achieves more accurate solutions than PSO, but also converges faster. However, NMPSO is not suitable for all kinds of problems, such as f5, f8 and f9, both PSO and NMPSO fail to solve these problems. To improve NMPSO further, we may introduce other search strategies. This will be investigated in our future work.

Keywords: real estate enterprises, financial risk, early-warning models

Abstract. With the establishment of large-scale real estate enterprises, the competition is increasing among real estate enterprises, which requires real estate companies to enhance crisis prevention awareness. In the paper a combination of qualitative and quantitative method is used aiming at certain risks that real estate enterprises are facing with. The article introduces the capacity of external financing in time, Eva, cash flow, board size, the scale of supervisor board and other new indicators to establish a new system of early warning indicators. The article provides empirical study from the perspective of early warning system of real estate generation enterprise using comprehensive evaluation model. It is more accurate to predict financial risk for real estate enterprises based on the qualitative method with quantitative method.

Introduction

The financial risks really exist in all aspects of enterprise management, which is the fact that enterprise has to face in financial management. Thus, better prevention and mitigation of risk and carrying out financial risk warning in financial management is based on a full understanding of the enterprise financial risk's type causes and characteristics. As a capital intensive enterprise, the real estate industry is unique, so are the financial risks of real estate enterprise. The real estate is the country's basic capital-intensive industries; the huge up-front investment, long-term infrastructure construction, uncertainty of return on investment, and financial barriers of entering and exiting the real estate industry are all its features. The real estate is a special product which has its own characteristics, such as location fixity, and the project is a kind of special investment. It takes huge funds and long return period. Therefore, the financial management of real estate enterprise subjects to many factors.

Constructe the Assessment Index System

The article builds two - level indicators on the basis of the financial risk of real estate companies which is different with general corporate. The first-class index includes six aspects of the analysis: solvency, capital structure, profitability, operating capacity, the capacity of development, corporate governance. Of these financial solvency, capital structure and profitability are the bases for enterprise financial evaluation. Operating capacity reflects the asset management efficiency. Capacity for development is the important indicators of sustainable development of enterprises. The perfecting corporate governance structures plays an important role in the development of the growth of enterprises which is conducive to prevent risks and improve operational efficiency. In second-class index ,the paper introduce external financing capacity, Eva divided by the main business income, net

cash flow divided by net income, board size, the scale of supervisor board, etc. which response the operation more comprehensive and effective. The index system as shown in Table Ⅰ.

Empirical Study

In order to study the comprehensive evaluation model of financial risk early warning better, the article take a power generation company for an example. The key of establishing the early warning model of real estate generation enterprise with fuzzy theory is to set up factor gather and weight gather.

TABLE I. INDICATOR SYSTEM

first-class index	second-class index	first-class index	second-class index
Solvency	current ratio	Operating Capacity	accounts receivable turnover
	quick ratio		inventory turnover rate
	number of times interest earned		total assets turnover
	external financing capacity		current asset turnover
Capital Structure	debt asset ratio	Development Capability	main income growth rate
	equity ratio		net profit growth rate
			growth rate of total assets
Profitability	operation profit of entirety		growth rate of net assets
	return on equity		EPS growth
	return on total assets	Corporate Governance	board size
	Eva divided by the main business income		The scale of supervisor board

Establish evaluate factors

$A=\{A_1, A_2, A_3, A_4, A_5, A_6\}=\{$ solvency, capital structure, profitability, operating capacity, development capability, corporate governance $\}$

$A_1=\{ a_{11}, a_{12}, a_{13}, a_{14}\}=\{$ current ratio, quick ratio, number of times interest earned, external financing capacity $\}$

$A_2=\{ a_{21}, a_{22}\}=\{$ debt asset ratio, equity ratio $\}$

$A_3=\{ a_{31}, a_{32}, a_{33}, a_{34}\}=\{$ operation profit of entirety, return on equity, return on total assets, Eva divided by the main business income $\}$

$A_4=\{ a_{41}, a_{42}, a_{43}, a_{44}\}=\{$ accounts receivable turnover, inventory turnover rate, total assets turnover, current asset turnover $\}$

$A_5=\{ a_{51}, a_{52}, a_{53}, a_{54}, a_{55}\}=\{$ main income growth rate, net profit growth rate, growth rate of total assets, growth rate of net assets, EPS growth $\}$

$A_6=\{a_{61}, a_{62}\}=\{$ board size, the scale of supervisor board $\}$

Evaluation indexes

U={Very safe ,safe, in general, dangerous, very dangerous}.

Weight sets

The key step is to structure the judgment matrix in the research question by using the AHP. First, judge the importance of the indicator by the expert method, then a second, structure the judgment matrix. Third, Find the eigenvalues and eigenvectors of the fuzzy judgment matrix, fourth, feature vector for normalized, finally, finally you can find the weight of the various indicators. However, it is important to do the consistency check after structuring the judgment matrix. If the Consistency Ratio is less than 0.1, than we think the discriminant matrix in this method satisfy the complete consistency, and it needs not to do the consistency check. On the contrary, we should make adjustments to the judgment matrix. In the paper, six judgment matrixes are constructed and composing weighing for

aide layer is calculated. They are V， V_1， V_2， V_3， V_4， V_5， V_6. The judgment matrix of every indicator and weight of the factors can be calculated.

Establish the evaluation matrix

The paper uses the methods of experts' investigation to evaluate the single factor. First, determine membership of the second-class index of solvency. The evaluation matrix is as follow.

$$R_1=\begin{bmatrix}0.02 & 0.09 & 0.21 & 0.44 & 0.24\\ 0.04 & 0.11 & 0.19 & 0.48 & 0.18\\ 0.03 & 0.10 & 0.22 & 0.45 & 0.20\\ 0.03 & 0.11 & 0.22 & 0.46 & 0.18\end{bmatrix}$$

Synthetic Appraisal to the Ability of Paying off a Debt

$$M_1=W_1\times R=[0.0281 \quad 0.0991 \quad 0.2070 \quad 0.4546 \quad 0.2112]$$

Second, determine membership of the second-class index of capital structure. The evaluation matrix is as follow.

$$R_2=\begin{bmatrix}0.07 & 0.10 & 0.20 & 0.37 & 0.26\\ 0.05 & 0.12 & 0.22 & 0.38 & 0.23\end{bmatrix}$$

Synthetic Appraisal to the capital structure

$$M_2=W_2\times R_2=[0.0633 \quad 0.1067 \quad 0.2067 \quad 0.3733 \quad 0.2500]$$

Third, determine membership of the second-class index of profitability. The evaluation matrix is as follow.

$$R_3=\begin{bmatrix}0.03 & 0.07 & 0.20 & 0.40 & 0.30\\ 0.05 & 0.10 & 0.21 & 0.41 & 0.23\\ 0.05 & 0.11 & 0.19 & 0.45 & 0.20\\ 0.06 & 0.13 & 0.18 & 0.43 & 0.20\end{bmatrix}$$

Synthetic Appraisal to the Ability of Profitability

$$M_3=W_3\times R_3=[0.0407 \quad 0.0889 \quad 0.1995 \quad 0.4129 \quad 0.2581]$$

Forth, determine membership of the second-class index of operating capacity. The evaluation matrix is as follow.

$$R_4=\begin{bmatrix}0.04 & 0.11 & 0.17 & 0.37 & 0.31\\ 0.05 & 0.11 & 0.21 & 0.36 & 0.27\\ 0.04 & 0.10 & 0.22 & 0.40 & 0.24\\ 0.05 & 0.11 & 0.20 & 0.40 & 0.24\end{bmatrix}$$

Synthetic Appraisal to the operating capacity

$$M_4=W_4\times R_4=[0.0435 \quad 0.1083 \quad 0.1916 \quad 0.3747 \quad 0.2819]$$

Five, determine membership of the second-class index of development capability. The evaluation matrix is as follow.

$$R_5=\begin{bmatrix}0.04 & 0.12 & 0.19 & 0.40 & 0.25\\ 0.04 & 0.18 & 0.20 & 0.33 & 0.25\\ 0.03 & 0.15 & 0.20 & 0.39 & 0.23\\ 0.05 & 0.17 & 0.21 & 0.35 & 0.22\\ 0.03 & 0.16 & 0.22 & 0.36 & 0.23\end{bmatrix}$$

Synthetic Appraisal to the Ability of Development

$$M_5=W_5\times R_5=[0.0391 \quad 0.1474 \quad 0.1973 \quad 0.3724 \quad 0.2438]$$

Six, determine membership of the second-class index of corporate governance. The evaluation matrix is as follow.

$$R_6=\begin{bmatrix}0.09 & 0.13 & 0.18 & 0.36 & 0.24\\ 0.07 & 0.13 & 0.14 & 0.39 & 0.27\end{bmatrix}$$

Synthetic Appraisal to the corporate governance

$$M_6=W_6\times R_6=[0.0850 \quad 0.1300 \quad 0.1700 \quad 0.3675 \quad 0.2475]$$

Finally, we can have the result of fuzzy comprehensive evaluation of real estate generation enterprise's financial risk.

$$R = \begin{bmatrix} 0.0281 & 0.0991 & 0.2070 & 0.4546 & 0.2112 \\ 0.0633 & 0.1067 & 0.2067 & 0.3733 & 0.2500 \\ 0.0407 & 0.0889 & 0.1995 & 0.4129 & 0.2581 \\ 0.0435 & 0.1083 & 0.1916 & 0.3747 & 0.2819 \\ 0.0391 & 0.1474 & 0.1973 & 0.3724 & 0.2438 \\ 0.0850 & 0.1300 & 0.1700 & 0.3675 & 0.2475 \end{bmatrix}$$

$$M = W \times R = [0.0441 \quad 0.1044 \quad 0.2021 \quad 0.4092 \quad 0.2403]$$

We can know from the result that final values of comprehensive evaluation are all positive values. And the value of the dangerous index is 0.4092 which is obviously the largest one. And the very dangerous index is 0.2403 which follows behind. Thus it can be seen this real estate generation enterprise runs very difficult and feels financial pressure. The company should take measures immediately which are important for the enterprises long-term development in order to reduce the financial risks.

Acknowledgement

It provides empirical study from the perspective of early warning system of real estate generation enterprise using comprehensive evaluation model. Then, considering the characteristics of real estate generation enterprise in our country, the financial risk forewarning index system is constructed. The article introduces the capacity of external financing in time, Eva, cash flow, board size, the scale of supervisor board and other new indicators. The paper shows how to perform the qualitative and quantitative analysis for the financial early-warning models. The example showing in the paper indicates that the real estate generation enterprise feels financial pressure. The company should strengthen management and improve the enterprise's financial information system. An effective way to guard against risk is to establish a financial early warning system and build healthy financial early warning institutions.

Keywords: Aerosol fire extinguishing agent; BP neural network; Genetic algorithms

Abstract. The aerosol fire extinguishing agent is a complex pyrotechnic composition, and the extinguishing efficiency need a series of experiments to identify. A method is put forward out based on combining back-propagation neural network and genetic algorithm (BP-GA) in this paper, and then the performance of aerosol fire extinguishing agent can be predicted in advance by the formulation. In the method, back-propagation (BP) algorithm was proposed to map the complex relationship between additive components and quality indexes of formulation. The genetic algorithm was employed to optimize the BP neural network weight and threshold. The results showed that the prediction display a satisfied consistence with the test and the error is less than 5%, and also indicated that the combining BP-GA method was an effective tool to predict the performance of aerosol fire extinguishing agent by the formulation designed.

Introduction

The pyrotechnic aerosol fire extinguishing agent (PAFEA) is a replacement to Halon [1] for its efficiency, economic and green. Due to the lack of various PAFEA combustion models, so it is necessary to through a great many of the experiments to get an ideal formulation. The conventional way is the oxygen balance analysis, the result is imprecise, the experiment is numerous and the scope is narrow.

Artificial Neural Network (ANN) model [2] have adaptive learning ability and memory capacity, it is proposed to solve complex nonlinear problems, its predict ability is better than multiple regression analysis and discriminant analysis. Among ANN models, the back-propagation (BP) neural network is the most well-known one. It has the advantage of simplicity and plasticity. However, it has some disadvantages. The algorithm is not guaranteed to find the global minimum of error space and the convergence tends to be extremely slow. In addition, the selection of the learning factor and momentum factor, which is usually determined by experience, also affects the convergence of the BP neural network. Genetic Algorithm (GA) is considered to be a heuristic and stochastic optimization technique based on evolution theory and genetic principles. The algorithm have some advantages that simple, universal, strong robustness and suitable for parallel processing. It has been widely used in computer science, optimal scheduling, transportation, combinatorial optimization problems and so on [3]-[6].

The method is proposed to improve the prediction of combustion performance by optimizing the network scenarios through coupling a back-propagation (BP) neural network with a genetic algorithm (GA). As two important performance parameters, the time ratio is that the extinguishing time divides by its combustion time, and burning residual ratio is that the mass of burning residual divided by the total mass of aerosol fire extinguishing agent. In this study, the time ratio and the burning residual ratio which are outputs are used in the method to predict results.

Model Building

This operation flowchart is shown in Figure 1. GA-BP network can be divided into three parts: the structure of the BP neural network, genetic algorithm to optimize and the prediction of BP neural network. According to the number of fitting function input and output parameters, BP neural network structure can be determined, and then the length of the genetic algorithm individual can be determined. Genetic algorithm optimization use genetic algorithm to optimize the BP neural network weight and threshold, the population of each individual contains a network all weight and threshold value. Genetic algorithm can find optimal fitness corresponding to the individual by selection, crossover and mutation operation. The initial weight and threshold value can be assigned by the best individual that though using genetic algorithm. After the network training, it can output prediction function. Genetic algorithm to optimize the BP neural network includes the population initialization, fitness function, selection, crossover operation and mutation operation.

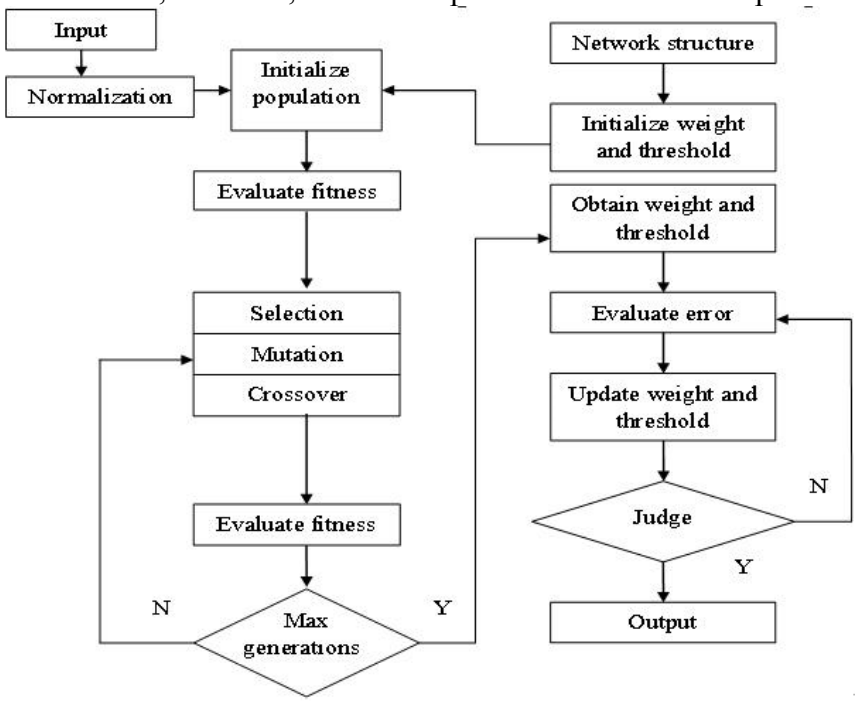

Figure1 Algorithm process

Model application

Pyrotechnic extinguishing agents consisted of oxidant, combustible and additives. The basic pyrotechnic formulation composed by potassium nitration (15%), strontium nitration (45%), lactose (10%-20%), phenolic resin (5%) and other functional additives. The purpose of this article is mainly for performance prediction of the formulation with different additives. Additive effect is to improve the efficiency of fire extinguishing, stable combustion performance and reduce the residual ratio. By using the method of orthogonal experiments design formulation, the selected orthogonal table $L_{25}(5^6)$ is shown in table 1.

Tab.1 Factors and Levels

Factors / Levels	Charcoal A%	Magnesium B%	Magnesium carbonate C%	Potassium hydrogen phthalate D%	Graphite E%	Ferrocee F%
1	0	0	0	2	0	0
2	1	0.4	1	3	0.2	0.5
3	2	0.6	2	4	0.4	1
4	3	0.8	3	5	0.8	1.5
5	4	1	4	6	1.6	2

According to the above methods, we designed 25 set of formulation and used the first 20 sets of data in table 2 for training, then forecasted 5 sets of data. The corresponding result is shown in table 3. The combustion performance of formulation was tested in a transparent acrylic box. The 1m3 acrylic box has a dimension of is 1m×1m×1m and has a side door. Inside the box, n-heptane was filled in an uncapped iron container (7cm diameter, 15cm depth) as the source of fire. The mixture (100g) in the burner is igniting by a fuse. The extinguishing time was determined from the recordings of the high speed camera. The residual mass is determined from the mass loss of the burner after burning. Experiment is shown below.

7	1	0.8	4	2	0.4	0.5	0.70	0.40
8	1	1	0	3	0.8	1	0.57	0.44
9	2	0.6	4	3	0	1.5	0.54	0.54
10	2	0.8	0	4	0.2	2	0.61	0.63
11	2	1	1	5	0.4	0	0.70	0.57
12	2	0.4	3	2	1.6	1	0.55	0.50
13	3	0.8	1	6	0	1	0.60	0.49
14	3	1	2	2	0.2	1.5	0.75	0.41
15	3	0.4	4	4	0.8	0	0.58	0.51
16	3	0.6	0	5	1.6	1	0.83	0.56

17	4	1	3	4	0	0.5	0.92	0.62
18	4	0	4	5	0.2	1	0.81	0.53
19	4	0.4	0	6	0.4	1.5	0.73	0.46
20	4	0.8	2	3	1.6	0	0.77	0.48
21	0	1	4	6	1.6	2	0.56	0.44
22	1	0	1	4	1.6	1.5	0.59	0.50
23	2	0	2	6	0.8	0.5	0.64	0.51
24	3	0	3	3	0.4	2	0.63	0.56
25	4	0.6	1	2	0.8	2	0.84	0.47

Table 2 shows the results of the twenty-five tests. The time ratio is defined as the extinguishing time divided by its combustion time. It can quickly measure the combustion stability of the fire extinguishing agent and the fire extinguishing efficiency. It also provides a simple and effective method to characterize performance formulation.

The there-layered GA-BP network used in this work has 6-15-2 structure, which consists of one input layer, one hidden layer and one output layer. The number of neurons in the input layer is six and there are two neurons in the output layer. The number of neurons in the hidden layer is fifteen. Figure3 presents the network model of training sample simulation result meeting the requirement of target error (0.00001) after 4183 step training. Moreover, in Figure3, it can be clearly seen that the results of network training is better. Figure 4 shows the best individual fitness value around 22 generation, the optimal initial weight and threshold value is assigned to neural network, and predict nonlinear function output after training with the training data. The prediction error is shown below.

Tab.3 Predicts of BP and GA-BP model

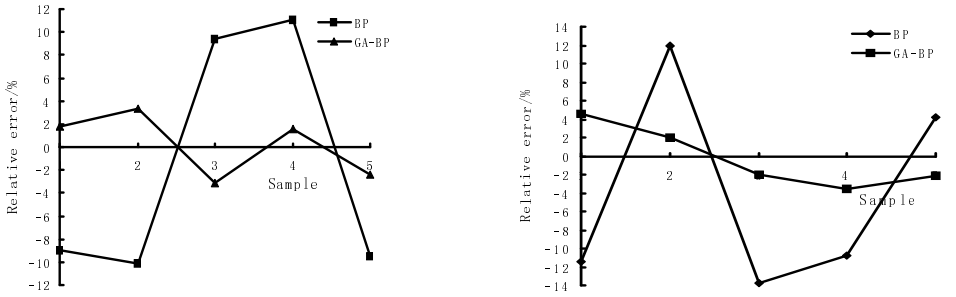
25	0.84	0.92	0.86	0.47	0.45	0.48



(a) The time ratio (b) The residual ratio

Fig.5 GA-BP and BP error contrast

Table 3 presents that the predicted results of GA-BP network and BP network are compared, it can be obviously found that the GA-BP network more close to the measured values. Figure 5 is the relative error curve of BP with GA-BP; it shows the residual ratio of the average relative error of the absolute value is 2.48% and the time ratio is 2.45%, both are less than 5%. But pure BP network to calculate the average relative error of the absolute value is 10.41% and 9.82%, respectively. In Figure 5, it can be obviously seen that the calculation precision of GA - BP network is higher than pure BP network, and the relative error of GA-BP curve is smooth, less volatile, has good stability,

but also reflects the simple BP network easy to fall into local minimum, and GA-BP network is a good solution.

Conclusion

The formulation of aerosol fire extinguishing agent were used as the input variable of GA-BP network, the time ratio and the burning residual ratio were as output variable. The results showed that the error was able to be less than 5% by using this method. The proposed model combining genetic algorithm (GA) and back-propagation (BP) algorithm has been shown as an actual method to map the complex relationship between process conditions.

The research shows that the model could replace the oxygen balance analysis, and performance simulation model could greatly reduce the amount of experiments and save cost. In spite of only 25 groups of training samples in the model, the data quantity is less, but a comparatively successful outcome else has been obtained. The modeling and optimization methods proposed in this article showed the great potential in complicated industrial applications.

Keywords: Gray map; Linear codes; One-Lee weight codes; Generator matrix.

Abstract. This paper is devoted to the study of the algebraic structure of one-Lee weight codes over $R_p = F_p + vF_p + v^2F_p$. We first give some necessary conditions for a code to be a one-Lee weight code over R_p. Moreover, we present the method of the construction of one-Lee weight codes over R_p. An example is given to illustrate the results.

Introduction

In coding theory, constant-weight (one-weight) codes form an important class of codes which have been extensively studied [1-4]. Cyclic codes and MacWilliams indentities were studied over R_p in [5-6]. Motivated by the work listed above, we intend to discuss one-Lee weight codes over R_p. This work is organized as follows. In Section 2, we recall some backgrounds and notations about linear codes over R_p. In Section 3, we construct one-Lee weight codes over R_p. An example is given to illustrate the results.

Preliminaries

We first recall some basic knowledge of [5] and [6]. Let R_p be the commutative ring $R_p = F_p + vF_p + v^2F_p$ with characteristic p, where $v^3 = v$. The elements of $x \in R_p$ may be written as $x = a + bv + cv^2, a, b, c \in F_p$. Any R_p-linear code C containing some nonzero codewords is permutation-equivalent to a R_p-linear code with a generator matrix of the form

$$\boldsymbol{G}=\begin{pmatrix}
\boldsymbol{I}_{k_1} & \boldsymbol{A} & \boldsymbol{B}_1+v\boldsymbol{B}_2 & \boldsymbol{C}_1+v\boldsymbol{C}_2 & \boldsymbol{D}_1+v\boldsymbol{D}_2 & \boldsymbol{E}_1+v\boldsymbol{E}_2 & \boldsymbol{F}_1+v\boldsymbol{F}_2 & \boldsymbol{G}_1 \\
\boldsymbol{0} & v\boldsymbol{I}_{k_2} & \boldsymbol{0} & \boldsymbol{0} & (v-1)\boldsymbol{D}_3+(v+1)\boldsymbol{D}_4 & v\boldsymbol{E}_3+(v-1)\boldsymbol{E}_4+(v+1)\boldsymbol{E}_5 & v\boldsymbol{F}_3+(v-1)\boldsymbol{F}_4+(v+1)\boldsymbol{F}_5 & \boldsymbol{G}_2 \\
\boldsymbol{0} & \boldsymbol{0} & (v-1)\boldsymbol{I}_{k_3} & \boldsymbol{0} & (v-1)\boldsymbol{D}_5+(v+1)\boldsymbol{D}_6 & (v-1)\boldsymbol{E}_6+(v+1)\boldsymbol{E}_7 & (v-1)\boldsymbol{F}_6+(v+1)\boldsymbol{F}_7 & \boldsymbol{G}_3 \\
\boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & (v+1)\boldsymbol{I}_{k_4} & (v+1)\boldsymbol{D}_7 & (v+1)\boldsymbol{E}_8 & (v+1)\boldsymbol{F}_8 & \boldsymbol{G}_4 \\
\boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & (v^2-1)\boldsymbol{I}_{k_5} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{G}_5 \\
\boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & (v+v^2)\boldsymbol{I}_{k_6} & \boldsymbol{0} & \boldsymbol{G}_6 \\
\boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & (v^2-v)\boldsymbol{I}_{k_7} & \boldsymbol{G}_7
\end{pmatrix},$$

where $\mathbf{G}_1 = \mathbf{G}_{11} + v\mathbf{G}_{12} + v^2\mathbf{G}_{13}, \mathbf{G}_2 = v\mathbf{G}_{21} + (v-1)\mathbf{G}_{22} + (v+1)\mathbf{G}_{23} + (v^2-1)\mathbf{G}_{24} + (v^2+v)\mathbf{G}_{25} + (v^2-v)\mathbf{G}_{26}, \mathbf{G}_3 = (v-1)\mathbf{G}_{31} + (v+1)\mathbf{G}_{32} + (v^2-1)\mathbf{G}_{33} + (v^2+v)\mathbf{G}_{34} + (v^2-v)\mathbf{G}_{35}, \mathbf{G}_4 = (v+1)\mathbf{G}_{41} + (v^2-1)\mathbf{G}_{42} + (v^2+v)\mathbf{G}_{43} + (v^2-v)\mathbf{G}_{44}, \mathbf{G}_5 = (v^2-1)\mathbf{G}_{51} + (v^2+v)\mathbf{G}_{52} + (v^2-v)\mathbf{G}_{53}, \mathbf{G}_6 = (v^2+v)\mathbf{G}_{61} + (v^2-v)\mathbf{G}_{62}, \mathbf{G}_7 = (v^2-v)\mathbf{G}_{71}, \mathbf{A}, \mathbf{B}_1, \mathbf{B}_2, \mathbf{C}_1, \mathbf{C}_2, \mathbf{D}_1 \sim \mathbf{D}_7, \mathbf{E}_1 \sim \mathbf{E}_8, \mathbf{F}_1 \sim \mathbf{F}_8, \mathbf{G}_{ij} (1 \le i \le 7, 1 \le j \le 6)$ are F_p-matrices, $\boldsymbol{I}_{k_i}$ are $k_i \times k_i$ identity matrices, C contains $p^{3k_1+2k_2+2k_3+2k_4+k_5+k_6}$ codewords.

Definition 2.1 The Gray map ϕ from R_p^n to F_p^{3n} is defined as $\phi(a+bv+cv^2)=(a,a+c,b)$ for $\forall a,b,c\in F_p^n$.

Definition 2.2 We divide the elements of R_p into D_i, $(i=0,1,2,3)$: $D_0=\{0\}$, $D_1=\{bv\,|\,b\in F_p^*\}\cup\{cv^2\,|\,c\in F_p^*\}\cup\{c-cv^2\,|\,c\in F_p^*\}$, $D_2=\{bv+cv^2\,|\,b,c\in F_p^*\}\cup\{a\,|\,a\in F_p^*\}\cup\{a+cv^2\,|\,a,c\in F_p^*,a+c\neq 0(\mathrm{mod}\,p)\}\cup\{a+bv-av^2\,|\,a,b\in F_p^*\}$, $D_3=\{a+bv\,|\,a,b\in F_p^*\}\cup\{a+bv+cv^2\,|\,a,b,c\in F_p^*,a+c\neq 0\,(\mathrm{mod}\,p)\}$

Definition 2.3 The Lee weight of $r\in R_p$ is defined as $w_L(r)=i,r\in D_i$, and the Lee weight of a codeword $c=(c_0,c_1,\cdots,c_{n-1})\in R_p^n$ is defined as $w_L(c)=\sum_{i=0}^{n-1}w_L(c_i)$.

One-Lee weight codes over R_p

In this subsection, we concentrate our study on one-Lee weight codes over R_p. We first give some necessary conditions for a linear code to be a one-Lee weight linear code over R_p.

Theorem 3.1 Suppose C is a one-Lee weight code of length n over R_p with generator matrix $\boldsymbol{G}$ with unique nonzero weight w_0, for $\forall c=(c_0,c_1,\cdots,c_{n-1})\in C$, set $n_x=|\{c_i\,|\,c_i=x,i=0,1,\cdots,n-1,x\in R_p\}|$, then we have the following two assertions:
(i) $n_{c-cv^2}=n_a=n_{a+cv^2}=n_{a+bv-av^2}=n_{a+bv}=n_{a+bv+cv^2}=0$ and $n_{bv}+n_{cv^2}+2n_{bv+cv^2}=w_0$; (ii) $n_{bv}=n_{cv^2}=n_{bv+cv^2}=n_a=n_{a+cv^2}=n_{a+bv-av^2}=n_{a+bv}=n_{a+bv+cv^2}=0$ and $n_{c-cv^2}=w_0$, where the meanings of a,b and c are identical with those of Definition 2.2.

Proof: Suppose C is a one-Lee weight code of length n over R_p with unique nonzero weight w_0, namely, for $\forall c\in C$, $w_L(c)=w_0$, according to Definition 2.3 , then we have :

$$w_L(c)=n_{bv}+n_{cv^2}+n_{c-cv^2}+2n_{bv+cv^2}+2n_a+2n_{a+cv^2}+2n_{a+bv-av^2}+3n_{a+bv}+3n_{a+bv+cv^2}=w_0,$$

$$w_L(bvc)=n_{bv}+n_{cv^2}+2n_{bv+cv^2}+n_a+n_{a+cv^2}+n_{a+bv-av^2}+2n_{a+bv}+2n_{a+bv+cv^2}=w_0\ or\ 0,$$

then $w_L(c)-w_L(bvc)=n_{c-cv^2}+n_a+n_{a+cv^2}+n_{a+bv-av^2}+n_{a+bv}+n_{a+bv+cv^2}=w_0\ or\ 0$, if $w_L(bvc)=w_0$, then $w_L(c)-w_L(bvc)=0$, which means (i); if $w_L(bvc)=0$, then $w_L(c)-w_L(bvc)=w_0$, which implies (ii).

Corollary 3.2 Suppose C is a one-Lee weight code of length n over R_p with generator matrix $\boldsymbol{G}$, then there isn't one-Lee weight code over R_p if $k_i,i=1,2,3,4,5,6,7$ satisfy the following five conditions: (i) $k_1>0,k_2,k_3,k_4,k_5,k_6,k_7\in N$; (ii) $k_3>0,k_1,k_2,k_4,k_5,k_6,k_7\in N$; (iii) $k_4>0,k_1,k_2,k_3,k_5,k_6,k_7\in N$; (iv) $k_5>0,k_1,k_2,k_3,k_4,k_6,k_7\in N$; (v) $k_7>0,k_1,k_2,k_3,k_4,k_5,k_6\in N$.

Lemma 3.3 For $\forall k\in\mathbb{Z}^+$, let N be the number of $(a_1,a_2,\cdots,a_k)$ which satisfy $\sum_{i=1}^{k}a_i\equiv av+av^2\ (\mathrm{mod}\ p),a\in F_p^*$, where $a_i\in\{av+av^2\,|\,a\in F_p\}$, then $N=p^{k-1}(p-1)$.

Proof : When $k=2$, clearly, $N=p(p-1)$, the result is valid. Assume the result is valid when $k=l$, namely, $N=p^{l-1}(p-1)$. If $k=l+1$, the number of $(a_1,a_2,\cdots,a_k)$ which satisfy $\sum_{i=1}^{l+1}a_i \equiv av+av^2 \pmod p$ is $p^{l+1}-p^{l-1}(p-1)-[p^l-p^{l-1}(p-1)]=p^l(p-1)$, where $a\in F_p^*$, $a_i\in\{av+av^2 \mid a\in F_p\}$, then the result follows by induction hypothesis.

Lemma 3.4 Let C be a linear code over R_p with type $p^{2k_2}p^{k_6}$ of length n. If $k_2=1$ and the columns of the generator matrix $G_{(k_6+1)\times n}$ are all distinct nonzero vectors $(c_0,c_1,\cdots,c_{k_6})^{\mathrm{T}}$, where $c_0\in\{av\mid a\in F_p\}\bigcup\{av^2\mid a\in F_p\}\bigcup\{av+bv^2\mid a,b\in F_p^*\}$, $c_i\in\{av+av^2\mid a\in F_p\}$, $i=1,2,\cdots,k_6$, then C is a one-Lee weight code of length $n=p^{k_6+2}-1$ with $w_0=2p^{k_6+1}(p-1)$.

Proof : Since the columns of the generator matrix are all distinct nonzero vectors, it follows that $n=p^{k_6+2}-1$. Let $r_0,r_1,\cdots,r_{k_6}$ be the rows of generator matrix G_{1,k_6}, where

$$r_0=(\underbrace{0,\cdots,0}_{p^{k_6}-1},\underbrace{v,\cdots,v}_{p^{k_6}},\underbrace{2v,\cdots,2v}_{p^{k_6}},\cdots,\underbrace{(p-1)v,\cdots,(p-1)v}_{p^{k_6}},\underbrace{v^2,\cdots,v^2}_{p^{k_6}},\underbrace{2v^2,\cdots,2v^2}_{p^{k_6}},\cdots,\underbrace{(p-1)v^2,\cdots,(p-1)v^2}_{p^{k_6}},$$
$$\underbrace{v+v^2,\cdots,v+v^2}_{p^{k_6}},\underbrace{v+2v^2,\cdots,v+2v^2}_{p^{k_6}},\cdots,\underbrace{(p-1)v+(p-1)v^2,\cdots,(p-1)v+(p-1)v^2}_{p^{k_6}}).$$

First we prove that $w_L(p_1r_1+p_2r_2+\cdots+p_{k_6}r_{k_6})=p^{k_6+2}$ for $\forall\, p_i\in F_p, 1\le i\le k_6$. Suppose $p_1=p_2=\cdots=p_k=1$, $p_{k+1}=p_{k+2}=\cdots=p_{k_6}=0$, $1\le k\le k_6$, by the form of r_0, set

$$\sum_{i=1}^{k}r_i=(\underbrace{r_{1,1},\cdots r_{1,p^{k_6}-1}}_{},\underbrace{r_{2,1},\cdots r_{2,p^{k_6}}}_{},\cdots\underbrace{r_{p^2,1},\cdots r_{p^2,p^{k_6}}}_{}).$$

By Lemma 3.3, for $\forall c_0\in\{av\mid a\in F_p\}\bigcup\{av^2\mid a\in F_p\}\bigcup\{av+bv^2\mid a,b\in F_p^*\}$, the number of vectors $(c_0,c_1,\cdots,c_{k_6})^{\mathrm{T}}$ such that $\sum_{i=1}^{k}c_i\equiv av+av^2 \pmod p$ is $p^{k_6-1}(p-1)$, where $a\in F_p^*$, namely, the number of $av+av^2$ in each section of r_0 is $p^{k_6-1}(p-1)$. Hence $w_L(\sum_{i=1}^{k}r_i)=p^2\times 2\times p^{k_6-1}(p-1)=2p^{k_6+1}(p-1)$, then $w_L(p_1r_1+p_2r_2+\cdots+p_{k_6}r_{k_6})=2p^{k_6+1}(p-1)$. Moreover, it is easy to see that $w_L(p_0r_0+p_1r_1+\cdots+p_{k_6}r_{k_6})=2p^{k_6+1}(p-1)$ for $\forall p_0\in\{av\mid a\in F_p\}\bigcup\{av^2\mid a\in F_p\}\bigcup\{av+bv^2\mid a,b\in F_p^*\}$, $p_i\in F_p$, $1\le i\le k_6$. Hence C is a one-Lee weight code with $w_0=2p^{k_6+1}(p-1)$.

Theorem 3.5 Let C be a linear code over R_p with type $p^{2k_2}p^{k_6}$ of length n. If the columns of the generator matrix $G_{(k_2+k_6)\times n}$ are all distinct nonzero vectors $(c_1,c_2,\cdots c_{k_2},c_{k_2+1},\cdots,c_{k_2+k_6})^{\mathrm{T}}$, where $c_i\in\{av\mid a\in F_p\}\bigcup\{av^2\mid a\in F_p\}\bigcup\{av+bv^2\mid a,b\in F_p^*\}, i=1,2,\cdots,k_2; c_j\in\{av+av^2\mid a\in F_p\}$, $j=k_2+1,\cdots,k_2+k_6$, then C is a one-Lee weight code with $w_0=2(p-1)p^{2k_2+k_6-1}$ and $n=p^{2k_2+k_6}-1$.

Proof: If $k_2=1$, the result follows from Lemma 3.4. Assume the result is valid for $\forall\, k_2=m$, we denote the generator matrix and the nonzero weight by G_{m,k_6} and $w_1=2(p-1)p^{2m+k_6-1}$, respectively, then for $k_2=m+1$, the generator matrix G_{m+1,k_6} of C is

$$\begin{pmatrix} \mathbf{0} & \mathbf{v} & \cdots & (p-1)\mathbf{v} & \mathbf{v^2} & \cdots & (p-1)\mathbf{v^2} & \mathbf{v}+\mathbf{v^2} & \mathbf{v}+2\mathbf{v^2} & \cdots & (p-1)\mathbf{v}+(p-1)\mathbf{v^2} \\ G_{m,k_6} & \tilde{G}_{m,k_6} & \cdots & \tilde{G}_{m,k_6} & \tilde{G}_{m,k_6} & \cdots & \tilde{G}_{m,k_6} & \tilde{G}_{m,k_6} & \tilde{G}_{m,k_6} & \cdots & \tilde{G}_{m,k_6} \end{pmatrix},$$

where $\mathbf{0}=(\underbrace{0,\cdots,0}_{p^{2m+k_6}-1})$, $\mathbf{i}=(\underbrace{i,\cdots,i}_{p^{2m+k_6}})$, $i\in\{av\mid a\in F_p\}\bigcup\{av^2\mid a\in F_p\}\bigcup\{av+bv^2\mid a,b\in F_p^*\}$, $\tilde{G}_{m,k_6}=(0_{m,k_6},G_{m,k_6})$, $0_{m,k_6}=(\underbrace{0,\cdots,0}_{m+k_6})^{\mathrm{T}}$, then C is a one-Lee weight code with $w_2=p^2w_1=2p^{2(m+1)+k_6-1}(p-1)$.

Next, we will consider the sum of all codewords of a linear code, which provide a new proof of Theorem 3.5.

Theorem 3.6 Suppose C is a linear code of length n over R_p with the generator matrix G, for $\forall j=1,\cdots,n,\exists c=(c_1,\cdots,c_n)\in C,c_j\neq 0$, then $\sum_{c\in C}w_L(c)=\dfrac{2n\mid C\mid(p-1)}{p}$.

Proof : Consider the $\mid c\mid\times n$ array of all codewords in C. It is easy to check that each column corresponds to one of the following cases:(1) the columns appears $0,cv+cv^2$ equally often, where $c\in F_p^*$; (2) the columns appears $0,bv,cv^2,bv+cv^2$ equally often, where $b,c\in F_p^*$; let N_1 be the number of the columns which appear $0,cv+cv^2$ equally often. Let N_2 be the number of the columns which appear $0,bv,cv^2,bv+cv^2$ equally often. Note that $N_1+N_2=n$, then

$$\sum_{c\in C}w_L(c)=N_1\left[\frac{\mid C\mid}{p}\times 2\times(p-1)\right]+N_2\left[\frac{\mid C\mid}{p^2}\times 2\times(p-1)+\frac{\mid C\mid}{p^2}\times 2\times(p-1)^2\right]=\frac{2n\mid C\mid(p-1)}{p}.$$

Note that: according to Theorem 3.6, if C is a one-Lee weight code of length n over R_p with the generator matrix G and w_0, then we have $(\mid C\mid-1)w_0=\dfrac{2n\mid C\mid(p-1)}{p}$. It is easy to verify that the results in Theorem 3.5 satisfy this equation.

Example 1 If $p=3$, $k_2=k_6=1$ according to Theorem 3.5, then there is a one-Lee weight code with $n=26$ and $w_0=36$, its generator matrix is

$$G_{1,1}=\begin{pmatrix} \mathbf{0} & \mathbf{v} & 2\mathbf{v} & \mathbf{v^2} & 2\mathbf{v^2} & \mathbf{v}+\mathbf{v^2} & \mathbf{v}+2\mathbf{v^2} & 2\mathbf{v}+\mathbf{v^2} & 2\mathbf{v}+2\mathbf{v^2} \\ G_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} & \tilde{G}_{0,1} \end{pmatrix}$$

where $G_{0,1}=(v+v^2,2v+2v^2)$, $\tilde{G}_{0,1}=(0,v+v^2,2v+2v^2)$, $\mathbf{i}=(i\ i),i\in\{av\mid a\in F_3^*\}\bigcup\{av^2\mid a\in F_3^*\}\bigcup\{av+bv^2\mid a,b\in F_3^*\}$, $\mathbf{0}=(0\ 0)$.

Abstract. In order to research dynamic network astringency reaching uniformity, this paper perfects the Vicsek model and puts forward improving dynamic network astringency efficiency by weighted model. We prove that the convergence rate of weighted model is faster than the classic Vicsek model and it can optimize dynamic network.

Introduction

Complexity and complex system is one of the focused research topics of 21 Century. Complex network is the important tool and method of describing and understanding complex system. It summarizes complex system as a network system constituted by multiple interactional individuals (panel points) and is widely used in different realms of science. It has become the focused research topic in complexity science realm and synchronously prevails among various complex network systems. Astringency is the core problem of dynamic network research, and has become one of the important and challengeable leading edges in system and control field. Dynamic network models, represented by Vicsek model, apply simple evolution rules but get complex self-organizing phenomenon and the research results provide cooperative control and coordination problem of multiple individual with theoretical basis. We conduct intense research on dynamic network modeling and network astringency ans put forward improving convergence efficiency by weighted model on the basis of Vicsek model. We prove that the convergence rate of weighted model is faster than the classic Vicsek model.

Vicsek Model and Its Heterogeneous Model

Vicsek Model: In Vicsek model, if we describe the relations of each individual and their neighbors by chart (or network), there will be a dynamic network where a topology changes every time because of individual motions. If we denote the chart of each moment by gt, a chart sequence G={g1，g2，…，gn}can be get. With the algebra graph theory and matrix, Literature [5-6] indicates that the system can reach an agreement when the sequence of the chart satisfy some certain conditions in topology

In the Vicsek model, N self-government individuals move on a L × L flat surface at the same rate. In the initial moment, the horizontal and vertical ordinate of each individual obey uniform distribution in [0， L], and the direction of each individual obey uniform distribution in[0，2π], as shown in Figure1.

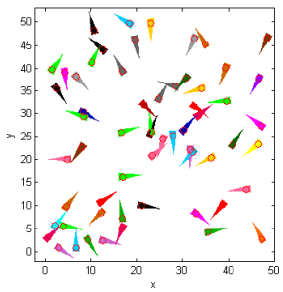

Figure 1: Original State

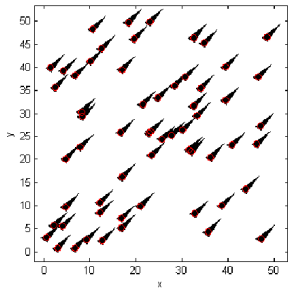

Figure 2: Consistent Direction State

In each t + 1 moment, the direction of each individual is the average value of the direction of one individual and its neighbor at t moment. At moment t + 1, the location change relation of individual i is shown in formula (1), and formula (2) determines its direction change.

$$x_i(t+1) = x_i(t) + v_0 e^{i\theta_i(t)} \tag{1}$$

$$e^{i\theta_i(t+1)} = e^{i\Delta\theta_i(t)} \frac{\sum_{j\in\Gamma_i(t+1)} e^{i\theta_j(t)}}{\| \sum_{j\in\Gamma_i(t+1)} e^{i\theta_j(t)} \|_2} \tag{2}$$

$\Delta\theta_i(t)$ is the white noise; $e^{i\theta_i(t)}$ is the unit direction vector; $\Gamma_i(t+1)$ is the neighbor gather of individual i at moment t + 1. When the destiny is relatively high and the noise is relatively low, the individual in system are in the same direction, as shown in Figure2.

Heterogeneous Model: Literature [7] brings forward the heterogeneous model in allusion to identical individual influence area and certain motion speed. In this model, the influence radius of each individual vary and obey the power-law distribution with the index of γ.

$$P(r) \to r^{-r} \qquad r \in [2, \infty] \tag{3}$$

When γ = ∞, the distribution of individual's influence radius is homogeneous, namely the influence radiuses equal. The research result shows that with the increase of the heterogeneous degree, namely the reduce of γ, the system convergence rate increases and the consistence degree improves.

Design and Analysis of Dynamic Network Weighted Model

Initial Conditions Definition of Modeling: Initial conditions are shown in Figure 1. N individuals distribute randomly on the L × L area of XY coordinate system, and the X, Y coordinates obey uniform distribution in [0， L]. The angle of each individual obey uniform distribution in[0， 2π].

The influence radiuses of each individual equal R. System noise is the data range of $\Delta\theta_i(t)$ in formula (2). In this paper, $\Delta\theta_i(t)$ obeys the uniform distribution in[−η ， η].

The model simulation study is achieved by loop iteration and the terminal condition of the loop, namely the convergence condition is formula （4）-（7）.

$$conc(t,t-1) = \sqrt{conc_r(t,t-1)^2 + conc_i(t,t-1)^2} \le 0.001 \tag{4}$$

$conc_r(t,t-1) \in R$ is shown in Formula (5). $conc_i(t,t-1) \in C$ is the complex number set as shown in formula (6). $\overline{e_{t,t-1}} \in C$ is shown in formula (7).

$$conc_r(t,t-1) \overset{\Delta}{=} \{\frac{1}{N-1}\sum_{j=1}^{N} real[(e^{i\theta_j(t)} - e^{i\theta_j(t-1)}) - \overline{e_{t,t-1}}]^2\}^{\frac{1}{2}} \tag{5}$$

$$conc_i(t,t-1) \overset{\Delta}{=} \{\frac{1}{N-1}\sum_{j=1}^{N} imag[(e^{i\theta_j(t)} - e^{i\theta_j(t-1)}) - \overline{e_{t,t-1}}]^2\}^{\frac{1}{2}} \tag{6}$$

$$\overline{e_{t,t-1}} \overset{\Delta}{=} \frac{1}{N-1}\sum_{j=1}^{N}[(e^{i\theta_j(t)} - e^{i\theta_j(t-1)}) \tag{7}$$

In order to make it convenient for study, the two aspect contained in convergence efficiency is defined as follows: convergence time t and degree of consistence SVa is expressed by formula (8).

$$V_a = |\sum_{i=1}^{n} e^{i\theta_j(t)} / N| \tag{9}$$

Dynamic Network Weighted Model: Currently, the research on complex network shows that various networks in reality have the feature of heterogeneous in topology structure. This paper considers improving the Vicsek model from the perspective of angle. We introduce the neighbor-number related weight and provide with the expression of direction change. We get the degree weighted model and name is model I, as shown in formula (10).

$$e^{i\theta_i(t+1)} = \frac{\sum_{j\in\Gamma_i(t+1)} \Gamma_j^{(1)}(t) e^{i\theta_j(t)}}{\| \sum_{j\in\Gamma_i(t+1)} \Gamma_j^{(1)} e^{i\theta_j(t)} \|_2} \tag{10}$$

$\Gamma_j^{(1)}$ is the weight of the neighbor j of individual I at moment t, and its computational formula is shown in formula (11). nj(t) is the neighbor number of individual i's neighbor j.

$$\Gamma_j^{(1)}(t) = \frac{n_j(t)}{\sum_{K\in\Gamma_i(t+1)} n_K(t)} \tag{11}$$

Adjust the discrepancy degree of individual weight and generate Vicsek model and model I to unmarked cases. When$\lambda > 1$, discrepancy degree of individual influence enlarges and the system convergence efficiency is higher than model I; conversely, when $0 < \lambda < 1$,the weight of individual with big angle is smaller than model I and the convergence efficiency is between original Vicsek model and model I. According to the direction update rule of formula (12), the direction of individual i is individual direction vector average of its neighbor who has the most neighbors.

$$e^{i\theta_i(t+1)} = \lim_{\lambda\to\infty} \frac{\sum_{j\in\Gamma_i(t+1)} \Gamma_j^{(1)}(t) e^{i\theta_j(t)}}{\| \sum_{j\in\Gamma_i(t+1)} \Gamma_j^{(1)} e^{i\theta_j(t)} \|_2} = \frac{\sum_{j\in\Omega(t+1,t)} e^{i\theta_j(t)}}{\| \sum_{j\in\Omega_i(t+1,t)} e^{i\theta_j(t)} \|_2} \tag{12}$$

Simulation Experimental Analysis

This paper focuses on researching the impact of the change of noise amplitudeη and angle indexλon system convergence efficient. Conduct simulation to weighted model and original Vicsek model and analyze comparatively. In the simulation process of this paper, when N=200， L=8, the conclusion adopt the average of 300 time simulations.

We can get from Figure 3 and Figure 4 that with the increase of noise amplitude, the system diminishes consistently; as to any fixed noise and radium, the consistence degree of model I is higher than the original Vicsek model; with the increase of noise amplitude, the system diminishes consistently; as to any fixed noise and V0, the consistence degree of model I is higher than the original Vicsek model.

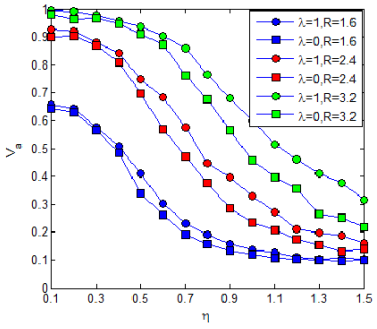

Figure 3: The Relation of Va and Noise Amplitude η when R changes

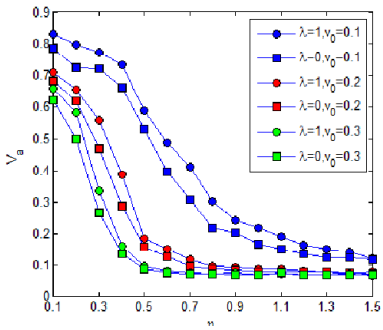

Figure 4: The Relation of Va and Noise Amplitude η when V 0 changes

Figure 5-6 shows the impact of indexλ on network. We can see from the figure that with the increase of index λ, convergence time t nearly shows the trend of exponential fall. With the increase of R and decrease of time, when the index increase to a certain degree, the influence of R is leveling out. It is thus clear that when the index λ is relatively small, R has a large influence on convergence time t, and when λ increases to some degree, the influence is not that important. Thus, the improvement this method to convergence time is effective. Index λ increase with the increase of the system consistence degree, which shows that this method can improve the system consistence degree.

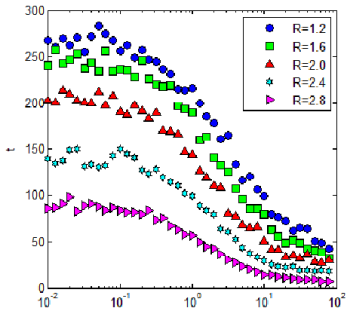

Figure 5: The Relation of λ and convergence time t

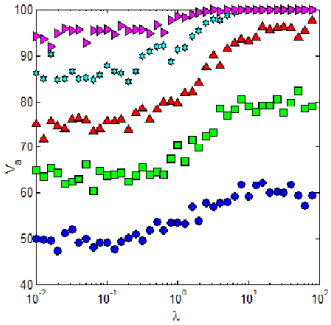

Figure 6: The Relation of λ and Consistent Va

Conclusion

Various networks in reality have the feature of heterogeneous in topology structure and panel point with big angle has a significance influence on the network structure and dynamics process in network. Considering that the discrepancy in neighbor number in the evolutionary process, this paper applies the dynamic network topology structure, and with combination of the definition of angle in complex network, it puts forward the angle-weighted weighting model to improve the convergence efficiency. Next moment direction of each individual in the weighted model is the vector weighted average of all neighbor directions current moment. Two models can be get according to the weighting differences, the weight of model I is in direct proportion to the individual degree (namely the mentioned neighbor number); the weight of model II is in direct proportion to the individual degree index and this index is greater than zero. The result shows that weighted model improve the convergence efficiency of dynamic network, so do the one with noise.

Keywords: Laplacian spectra, the Laplacian characteristic polynomials, Laplacian integral graphs.

Abstract. Graph G is Laplacian integral, if all the eigenvalues of its Laplacian matrix are integral. In this paper, we obtain that the Laplacian characteristic polynomials of graphs $K_n^{-tk_2}$ by calculation. Characterizes the new class of Laplacian integral graphs .

Introduction

All the graphs considered in this paper are finite, undirected and simple. Undefined notations and terminology will conform to those in [1, 2].

Let G be a graph with vertex set $V(G)$ and edge set $E(G)$. Let $A(G)$ be the (0, 1)-adjacency matrix of graph G. The Laplacian matrix and the signless Laplacian matrix of G is defined to be $L(G) = D(G) - A(G)$ and $Q(G) = D(G) + A(G)$, respectively, where $D(G)$ is the diagonal matrix of vertex degrees of G. We call $P_G(\lambda) = |\lambda I - A(G)|$, $L_G(\lambda) = |\lambda I - L(G)|$ and $Q_G(\lambda) = |\lambda I - Q(G)|$, respectively, the characteristic polynomial of G with respect to the adjacency matrix, the Laplacian matrix and the signless Laplacian matrix of graph G, see [2, 3]. Let $\lambda_1, \lambda_2 \cdots, \lambda_n$ be n distinct Laplacian eigenvalues with the corresponding multiplicities $k_1, k_2 \cdots, k_n$. We denote by

$$Spec(G) = \{\lambda_1^{k_1}, \lambda_2^{k_2}, \cdots, \lambda_n^{kn}\}$$

The Laplacian spectrum of graph G.

Let $K_{n_1,n_2,\cdots,n_t}$ denote the complete t-partite graphs with t partite sets A_i's such that $|A_i| = n_i$ for $i = 1,2,\cdots,t$. Assume that the number of distinct integers of $n_2, n_2, \cdots, n_t$ is s. Without loss of generality, assume that $n_2 < n_2 < \cdots < n_s$. Suppose that a_i is the multiplicity of n_i for each $i = 1,2,\cdots,s$. The complete t-partite graphs $K_{n_1,n_2,\cdots,n_t} = K_{n_1,\cdots,\ n_1,\cdots,n_s\cdots,n_s}$ is also denoted by $K_{a_1n_1,\cdots,a_sn_s}$, where $r = \sum_{i=1}^{s} a_i$ and $|V| = n = \sum_{i=1}^{s} a_i n_i$.

$K_{1,n}$ is called a star. $S(p,q)\ (p \le q)$ is called a double-star like tree on $n = p + q$ vertices.

The line graph $L(G)$ of a graph G is the graph whose vertices correspond to the edges of G with two vertices being adjacent if and only if the corresponding edges in G have a vertex in common.

A graph is integral, Laplacian integral and Q-integral if all the eigenvalues of its adjacency matrix, Laplacian matrix and signless Laplacian matrix, respectively, are integral.

The search for integral graph started already in 1970s [4] and has continued to this day so far. Many integral graphs have been found or characterized in various graph class, see [5, 6]. Some interesting results on Laplacian integral graphs can be found in [7, 8]. However, the signless Laplacian spectral is not much studied in the literature. Very recently, the authors in [9-12] investigated the characteristic polynomial of the signless Laplacian matrix.

Problem: Determine all connected, nonregular graphs that are integral, Laplacian integral and signless Laplacian integral.

In [9-13], we obtain that the signless Laplacian characteristic polynomials of the complete multipartite graphs $G = K_{n_1,n_2,\cdots,n_t}$. Also obtain that the characteristic polynomial of the signless Laplacian matrix of the complete t-partite graphs $G = K_{n_1,n_2,\cdots,n_t} = K_{n_1,\cdots,\ n_1,\cdots,n_s\cdots,n_s}$. Showed that the necessary and sufficient condition for the complete t-partite graphs $G = K_{n_1,n_2,\cdots,n_t} = K_{n_1,\cdots,\ n_1,\cdots,n_s\cdots,n_s}$, where $s = 2,3,4$ to be Q-integral. And proved that all the complete multipartite graphs $G = K_{n_1,n_2,\cdots,n_t} = K_{n_1,\cdots,\ n_1,\cdots,n_s\cdots,n_s}$ are Laplacian integral graphs.

In this paper, we obtain that the Laplacian characteristic polynomials of graphs $K_n^{-tk_2}$ by calculation. Characterizes the new class of Laplacian integral graphs.

Preliminaries

Theorem 1.1 [13] Let $G = K_{n_1,\cdots,\ n_1,\cdots,n_s\cdots,n_s}$ be complete multipartite graphs on n vertices. Then graph G is Laplacian integral. And its Laplacian spectrum is

$$Spec(G) = \{0^1, n^{s-1}, (n_1 - n)^{(n_1-1)a_1}, \cdots, (n_s - n)^{(n_s-1)a^s}, n^{a_1-1}, \cdots, n^{a_s-1}\}$$

Where, $n = a_1 n_1 + a_2 n_2 + \cdots + a_s n_s$.

Let K_n be complete graph on n vertices. Let $K_n^{-tk_2}$ denote the graphs obtained by deleting $t, 0 < t \le \frac{1}{2}$ non-adjacent edges from the complete graph K_n. The description on the new class of the integral graph is little, so with good prospects for the study. In this paper, we main calculate the Laplacian characteristic polynomials of graphs $K_n^{-tk_2}$, and characterizes the new class of Laplacian integral graphs.

Laplacian characteristic polynomials of graphs $K_n^{-tk_2}$

Theorem 2.1 Let $G = K_n^{-tk_2}$ denote the graphs obtained by deleting $t, 0 < t \le \frac{1}{2}$ non-adjacent edges from the complete graph K_n. Then G is Laplacian integral. And the Laplacian characteristic polynomials of $G = K_n^{-tk_2}$ is:

(1)When n be odd, and $t = \frac{n-1}{2}$, $L_G(\lambda) = \lambda[\lambda - (n-2)]^t (\lambda - n)^t$;

(2)When n be even, and $t = \frac{n}{2}$, $L_G(\lambda) = \lambda[\lambda - (n-2)]^t (\lambda - n)^{t-1}$.

Prove: (1) When n be odd, and $t = \frac{n-1}{2}$. The Laplacian characteristic polynomials of G is:

$$L_G(\lambda)=\begin{vmatrix} \lambda-(n-1) & 1 & 1 & \cdots & 1 & 1 \\ 1 & \lambda-(n-2) & 0 & \cdots & 1 & 1 \\ 1 & 0 & \lambda-(n-2) & \cdots & 1 & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & 1 & \cdots & \lambda-(n-2) & 0 \\ 1 & 1 & 1 & \cdots & 0 & \lambda-(n-2) \end{vmatrix}$$

Using the elementary transformation of determinant, we have,

$$L_G(\lambda)=\lambda\,[\lambda-(n-2)]^{\frac{n-1}{2}}\,(\lambda-n)^{\frac{n-1}{2}}=\lambda\,[\lambda-(n-2)]^{t}\,(\lambda-n)^{t}.$$

(2)When n be even, and $t=\dfrac{n-1}{2}$, The Laplacian characteristic polynomials of G is:

$$L_G(\lambda)=\begin{vmatrix} \lambda-(n-2) & 0 & \cdots & 1 & 1 \\ 0 & \lambda-(n-2) & \cdots & 1 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & \lambda-(n-2) & 0 \\ 1 & 1 & \cdots & 0 & \lambda-(n-2) \end{vmatrix}$$

Using the elementary transformation of determinant, Obtained,

$$L_G(\lambda) \;=\; \lambda\,[\lambda-(n-2)]^{\frac{n}{2}}\,(\lambda-n)^{\frac{n}{2}-1}=\lambda[\lambda-(n-2)]^{t}(\lambda-n)^{t-1}.$$

Corollary 2.1 Let $G=K_n^{-k_2}$ denote the graphs obtained by deleting 1 edges from the complete graph K_n. Then $G=K_n^{-k_2}$ is Laplacian integral. And its Laplacian spectrum is:

$$Spec(G)=\{0^1,(n-2)^1,n^{n-2}\}$$

Corollary 2.2 Let $G=K_n^{-2k_2}$ denote the graphs obtained by deleting 2 edges from the complete graph K_n. Then $G=K_n^{-2k_2}$ is Laplacian integral. And its Laplacian spectrum is:

$$Spec(G)=\{0^1,(n-2)^2,n^{n-3}\}$$

The Laplacian characteristic polynomials of line graph of star

Theorem3.1 Let $G=L(K_{1,\,n})$ be line graph of star $K_{1,n}$ on $n+1$ vertices. That is the complete graph K_n on n vertices. Then $K_{1,n}$ is Laplacian integral. And its Laplacian spectrum is:

$$Spec(G)=\{0^1,(n-1)^{n-2}\}$$

Theorem3.2 Let $G=L(S_{(p,\,q)})$ be line graph of double-star like tree $S_{(p,\,q)}$ on $n=p+q$ vertices. Then the Laplacian characteristic polynomials of graph $G=L(S_{(p,\,q)})$ is:

$$L_G(\lambda) \;=\lambda(\lambda-1)(\lambda-p)^{p-2}(\lambda-q)^{q-2}[\lambda-(p+q-1)].$$

Prove: The Laplacian characteristic polynomials of graph $G=L(S_{(p,\,q)})$ is:

$$L_G(\lambda)=\begin{vmatrix} A & O & J_1 \\ O & B & J_2 \\ J_3 & J_4 & \lambda-(p+q-2) \end{vmatrix},$$

Where, $A=\begin{bmatrix} \lambda-(p-1) & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & 1 & \lambda-(p-1) \end{bmatrix}$, $B=\begin{bmatrix} \lambda-(q-1) & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & 1 & \lambda-(q-1) \end{bmatrix}$.

J_i $(i=1,2,3,4)$ denote the $(p-1)\times 1, (q-1)\times 1, 1\times(p-1), 1\times(q-1)$ all-one matrices.

Using the elementary transformation of determinant, Obtained,

$$L_G(\lambda)=\lambda(\lambda-1)(\lambda-p)^{p-2}(\lambda-q)^{q-2}[\lambda-(p+q-1)]$$

Keywords: Interconnect; Crosstalk Noise; Process Variations;

Abstract. To solve the crosstalk noise question in deep-submicron technologies, an efficient methodology for estimating interconnect crosstalk noise is proposed in this paper. PCA and ICA techniques are applied to reduce correlations of process variations, and moment matching scheme is used to obtain the PDF of crosstalk noise in victim coupled with multiple aggressors. Experimental results show that our method maintains the efficiency of past approaches, and significantly improves on their accuracy.

1. Introduction

On-chip interconnect is known as one of the most compelling problems for modern deep submicron integrated circuits, and interconnects are going to be the limiting factor for high speed digital circuits. Another unwanted side effect of CMOS process technology scaling is the increase in process variations. Differences between identical features in a certain lithographic process are referred to as process variations [1]. Lithography steps generate more process variations in smaller geometric feature sizes. This phenomenon can create a rather large deviation of key circuit parameters from their designed values, which in turn may increase crosstalk, produce timing uncertainty, interferer circuit performance [2], and demand highly sophisticated and robust crosstalk-aware analysis and optimization tools.

Statistical analysis is viewed as an essential methodology for nanometer process technologies, which enables the application of actual statistics of the process technology parameters for the accurate calculation of design characteristics such as delay and noise [3]. Most approaches assume that parameter variables are known statistically Gaussian independent。However, it is well known that some process parameters deviate significantly from a Gaussian distribution [4]. For example, via resistances exhibit an asymmetric probability distribution, and the dopant concentration density is also observed to be well-modeled by a Poisson distribution. A normality assumption may lead to significant sources of errors in crosstalk noise analysis.

In this paper, a new methodology is proposed to derive the statistical distribution of on-chip crosstalk noise, which presents a solution in the presence of both correlated Gaussian and non-Gaussian parameter distributions. Further the paper is organized as following: In section 2, PCA and ICA technologies are employed to transform correlated sets of Gaussian and non-Gaussian variables to sets of statistically independent variables correspondingly, and then the PDF of crosstalk noise in a victim line coupled with multiple aggressors is obtained using the moment matching scheme. Section 3 shows experimental results while section 4 concludes this paper.

2. PDF evaluation of crosstalk noise

When correlations among process parameters are taken into consideration, the statistical crosstalk noise analysis becomes even more complicated. To make the problem tractable, we employ the mathematical techniques PCA (principal components analysis) [5] and ICA(independent component analysis) [6] to accomplish the desired goal of transforming Gaussian and non-Gaussian correlated random variables sets in reduced distributed RC-π model to random variables sets that are

statistically as independent as possible, respectively. Then, crosstalk noises can be represented in a linear form of new sets of independent Gaussian and non-Gaussian random variables.

In Eq. (1), ICA is applied to the non-Gaussian parameters X and PCA to the Gaussian variables Y, to obtain a set of statistically independent non-Gaussian variables S and a set of independent Gaussian variables R. We then arrive at the following canonical noise model:

$$V = \mu + B'^T S + C'^T R + e \cdot z = \mu + \sum_{i=1}^{n} b_i' \cdot s_i + \sum_{j=1}^{m} c_j' \cdot r_j + e \cdot z \tag{1}$$

where $B'^T = B^T A$ [$C'^T = C^T P_y^{-1}$] is the new sensitivity vector with respect to the statistically independent non-Gaussian components $s_1, s_2, ..., s_n$ [Gaussian principal components $r_1, r_2, ..., r_m$], A[P_y] is the n× n [m× m] transformation matrices.

Given the underlying process variables and their moments, after performing ICA [PCA] the moments of the independent components $s_1, s_2, ..., s_n$ [$r_1, r_2, ..., r_m$] can be easily computed successively from the moments of the correlated non-Gaussian parameters $x_1, x_2, ..., x_n$ [correlated Gaussian parameters $y_1, y_2, ..., y_m$]. These moments of the process variables are inputs to the RD-SCNA algorithm.

Finally, to compute the PDF/CDF of the crosstalk noise random variable we adapt the probability extraction scheme *APEX* [7]. Given 2*M* moments of a random variable as inputs to the *APEX* algorithm, the scheme employs an AWE (asymptotic waveform evaluate) technique to match the 2*M* moments in order to generate an *M*th order LTI (linear time invariant) system. The scheme then approximates the PDF [CDF] of a random variable in reduced distributed RC-π model by an impulse response $h(t)$ [step response $s(t)$] of the *M*th order LTI system.

It is clear that we borrow some techniques from existing algorithm; however, the overall algorithm is distinctly different from any existing crosstalk noise analysis method.

We use a simple 2 RC-π stages circuit of a pair of coupled interconnect lines, shown in Fig. 1, to illustrate the moment matching-based PDF evaluation. We assume the width *W* and the height *H* for each interconnect to be the random variables. Using a first order approximation, the crosstalk noise of this circuit can be written as:

$$V = \mu + a_{1a}W_{1a} + a_{2a}W_{2a} + a_{1v}W_{1v} + a_{2v}W_{2v} + b_{1a}H_{1a} + b_{2a}H_{2a} + b_{1v}H_{1v} + b_{2v}H_{2v}$$

where $a_{1a}, a_{1v}, b_{1a}, b_{1v}$ [$a_{2a}, a_{2v}, b_{2a}, b_{2v}$] are sensitivities of the crosstalk noise with respect to the zero-mean randomly varying parameters $W_{1a}, W_{1v}, H_{1a}, H_{1v}$ [W_{2a}, W_{2v}, H_{2a}, H_{2v}] of seg-1 [seg-2], respectively, and μ is the nominal crosstalk noise of the circuit.

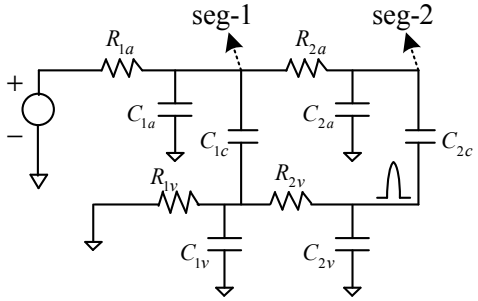

Fig. 1 Two RC-π stages circuit of coupled interconnect lines

Assuming ($W_{1a}, W_{2a}, W_{1v}, W_{2v}$) to be perfectly correlated identical Gaussian random variables, and ($H_{1a}, H_{2a}, H_{1v}, H_{2v}$) to be perfectly correlated, and uniformly distributed identical random variables, we have:

$$\hat{V} = a \cdot W + b \cdot H$$

where $a = a_{1a} + a_{2a} + a_{1v} + a_{2v}$, $b = b_{1a} + b_{2a} + b_{1v} + b_{2v}$, $\hat{V} = V - \mu$.

Assuming *W* and *H* as statistically independent variables, the kth moment of $\hat{V}$ can be computed by using the binomial expansion formula as:

$$m_k[\hat{V}] = \sum_{i=0}^{k} \binom{k}{i} a^i b^{k-i} m_i(W) m_{k-i}(H) \tag{2}$$

where all of the k moments of W and H are known from the underlying normal and uniform distribution. Having computed $2M$ moments of $\hat{V}$ from Eq. (2), we can now employ the AWE-based PDF evaluation scheme to approximate the PDF of $\hat{V}$ by an impulse response as:

$$f_{\hat{V}}(\hat{v}) = \begin{cases} \sum_{i=1}^{M} \hat{r}_i \cdot e^{\hat{p}_i \cdot \hat{v}} & \hat{v} \geq 0 \\ 0 & \hat{v} < 0 \end{cases}$$

where $\hat{r}[\hat{p}]$ are the residues [poles] of the LTI approximation.

Then, the evaluated crosstalk noise PDF is shown as: $f_V(v) = f_{\hat{V}}(v + \mu)$

We can generalize the PDF evaluation idea, illustrated in the above example, to compute the PDF (CDF) of any crosstalk noise random variable expressed in the canonical form of Eq. (1).

It is well known that a victim usually has multiple aggressors switching simultaneously. The crosstalk noise in a victim is the superposition of crosstalk noise generated by each coupled aggressors. When the induced crosstalk glitches in victim switch in opposite directions, the generated crosstalk noise effect can be counteracted with each other. Thus, the proposed crosstalk noise computation procedure in reduced distributed RC-π model involves two atomic operations of "sum" and "subtraction". Consider two random variables, V_1 and V_2 expressed as:

$$V_1 = \mu_1 + \sum_{i=1}^{n} b'_{i_1} \cdot s_i + \sum_{j=1}^{m} c'_{j_1} \cdot r_j + e_1 \cdot z_1, \quad V_2 = \mu_2 + \sum_{i=1}^{n} b'_{i_2} \cdot s_i + \sum_{j=1}^{m} c'_{j_2} \cdot r_j + e_2 \cdot z_2$$

The sum V_3 of V_1 and V_2 can be expressed in canonical form as:

$$V_3 = \mu_3 + \sum_{i=1}^{n} b'_{i_3} \cdot s_i + \sum_{j=1}^{m} c'_{j_3} \cdot r_j + e_3 \cdot z_3$$

where $\mu_3 = \mu_1 + \mu_2$, $b'_{i_3} = b'_{i_1} + b'_{i_2}$, $c'_{j_3} = c'_{j_1} + c'_{j_2}$, and $e_3 z_3 = e_1 z_1 + e_2 z_2$.

The uncorrelated non-Gaussian random variable $e_3 z_3$ serves as a place holder to store the moments of $(e_1 z_1 + e_2 z_2)$. In other words, rather than propagating an uncorrelated component z in the canonical form, we propagate its $2M$ moments. The "subtraction" operation of crosstalk noise random variable is similar with its "sum" operation. So, the proposed superposition operation of crosstalk noise random variables expressed in the linear canonical form of Eq. (1) is largely straightforward.

3. Experimental results

Fig. 2 shows a comparison of the results of our method with those generated from the Monte Carlo (MC) simulation for the test circuit using 2000 samples. As seen in Fig. 2, the results of the proposed approach are able to match well with those of MC simulations within small errors. These errors are reasonably small as compared to the accuracy penalty paid when modeling the non-Gaussian parameters as normally distributed random variables and performing MC simulations, termed as $\mathrm{MC}_{\mathrm{Gauss}}$, for test circuit. Thus, modeling the non-Gaussian parameters as normally distributed ones leads to significant inaccuracy. Moreover, to show the importance of considering spatial correlations, we consider the difference between performing statistical crosstalk noise analysis while considering spatial correlation and while ignoring it. Therefore, we run another set of Monte Carlo simulations, termed as $\mathrm{MC}_{\mathrm{NoCorr}}$, on the same test circuit, this time assuming zero correlations among segments. It can be observed in Fig.2 that the CDF and PDF curves of $\mathrm{MC}_{\mathrm{NoCorr}}$ deviate significantly from those of MC simulations. Thus, statistical crosstalk noise analysis without considering correlation may incorrectly predict the real performance of the circuit and could even overestimate the performance of the circuit. This underlines the importance of developing efficient statistical crosstalk noise analysis methods that can incorporate spatial correlations.

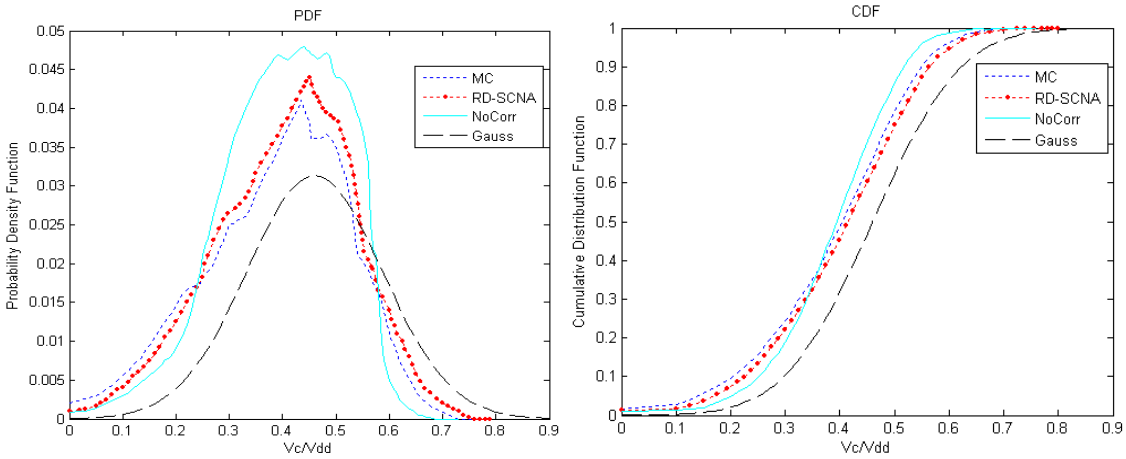

Fig. 2 Comparisons of RD-SCNA and MC distributions

4. Conclusions

As the VLSI technology scales down the role of interconnect parasitic effects in the signal integrity becomes increasingly significant, resulting in the aggravation of crosstalk noise amplitude and duration, and the circuit faults. In this paper a new crosstalk noise analysis method in deep-micron technologies was presented. The proposed method is able to obtain a very precise crosstalk noise result of the victim coupled with multiple aggressors, and general enough to work even for the cases when the PDF of the sources of variation is not available by using moment matching scheme. Experimental results show that compared to previous methods our approach significantly improves the crosstalk analysis accuracy by handling a larger range of variables while maintaining the efficiency.

Keywords: 3-D reconstruction; 3-D estimated trajectory; ORB; image features; SLAM

Abstract. In this paper, a novel feature-based real-time visual Simultaneous localization and mapping (SLAM) system is proposed. This system generates colored 3-D reconstruction models and 3-D estimated trajectory using a Kinect style camera. Microsoft Kinect, a low priced 3-D camera, is the only sensor we use in our experiment. Kinect style sensors give RGB-D (red-green-blue depth) data which contains 2D image and per-pixel depth information. ORB (Oriented FAST and Rotated BRIEF) is the algorithm used to extract image features for speed up the whole system. Our system can be used to generate 3-D detailed reconstruction models. Furthermore, an estimated 3D trajectory of the sensor is given in this paper. The results of the experiments demonstrate that our system performs robustly and effectively in both getting detailed 3D models and mapping camera trajectory.

Introduction

How to use simultaneous localization and mapping (SLAM) effectively and robustly has been one of the most actively studied problems in the robotics community over the past decade. Recently, a variety of 3D SLAM algorithms supports 6-DOF (degree-of-freedom) pose optimization, therefore the SLAM technique is employed in various platforms like quadrotors, underwater robots, etc.

As 3D cameras previously existed only as very expensive devices, the research into algorithms for analysis of their data is limited. However, the situation had been changed since the Microsoft Kinect sensor has been introduced into the market as a low priced 3D camera and now there is a significant increase in research into such algorithms. The Kinect sensor contains a depth sensor and a color camera. The depth sensor obtains depth data using the IR (infrared) projection method. Figures 1 (a) and (b) show a color image and depth data from the Kinect sensor. The Kinect style sensors are called the RGB-D (red-green-blue depth) camera since they give the color image and the depth data at the same time.

Fioraio and Konolige [1] presented a system that uses bundle adjustment to align the dense point clouds of the Kinect directly however without further exploiting the RGB images. Peter Henry *et al.* [2] introduced RGB-D mapping using RGB-D cameras to generate dense 3D models of indoor environments. Their approach detects loop closures by matching data frames against a subset of previously collected frames. To generate globally consistent alignments they use TORO, an optimization tool developed for SLAM [3]. The overall system can accurately align and map large indoor environments in near-real time and is capable of handling special situations such as featureless corridors and completely dark rooms. But this work did not operate in real-time. Felix Endres *et al.* [4] implemented and evaluated 3D SLAM with a variety of feature descriptors, the ICP algorithm, and the g2o (General framework for Graph Optimization) SLAM framework. They also presented a novel benchmark for the evaluation of their RGB-D SLAM systems [5]. Donghwa Lee *et al.* [6] proposed RGB-D 3D SLAM system which has the processing rate over 20 Hz. The image feature detection is performed on the GPU processor. However, both Felix Endres *et al.* and Donghwa Lee *et al.* didn't present the 3D estimated trajectory of their sensors.

In this paper, we propose a feature-based real-time visual SLAM system which can generate 3D models of objects and the 3D trajectory of the Kinect style sensors. The feature descriptor we use in this system is ORB [7]. The paper is organized as follows. The second section presents the

framework of real-time 3D reconstruction and estimated 3D sensor trajectory in our system. The third section provides experimental results. The last section comes to the conclusions.

(a) (b)

Fig.1. RGB-D sensor system. (a) RGB color image. (b) Per-pixel depth data.

Proposed SLAM System

Our approach utilizes RGB images and depth data from a RGB-D sensor. Processing steps of our system are as follows. First, we extract ORB features from the incoming color images. Each feature can be located at a point in three-dimensional coordinate space with depth information. These features will be matched against features from the previous images. Then we obtain a set of point-wise 3D correspondences between any two frames. Second, the relative transformation between the frames is estimated using Random Sample Consensus (RANSAC) [8]. Third, a feature manager gathers the whole features from the previous frames. Through comparison between the current and the preceding features, the current frame is matched to a past trajectory of the sensor. This matching procedure is called loop closure detection. Finally, we obtain the 3D trajectory and 3D object models after optimizing the constraint graph by the online graph-based SLAM algorithm. The detailed introduction of this system is given as follows:

A. Feature Extraction and Matching

ORB algorithm is used to extract image features from the incoming color image of the sensor and match to the feature of the previous frame in this system, as shown in figure 3. ORB is a very fast binary descriptor based on BRIEF and it is rotation invariant and resistant to noise. This algorithm is less accurate and less reliable, but is much faster than SIFT and SURF. Besides, ORB can implement the feature extraction procedure in real-time (30 Hz image frequency) on CPU in OpenCV 2.4.8.

B. RANSAC

RANSAC is a very important algorithm to compute the relative 3D transformation between the sensor poses and also to cope with noisy data and outliers in this system. After matching the features of two frames, the RANSAC approach randomly select a set of three matched feature pairs to compute a rigid transformation. If the Euclidean distances of the samples match, RANSAC will employ them to compute an estimate of the rigid transformation. The transformation is applied to all matched features to select all inliers. Finally, the inliers selected are used to compute a refined transformation.

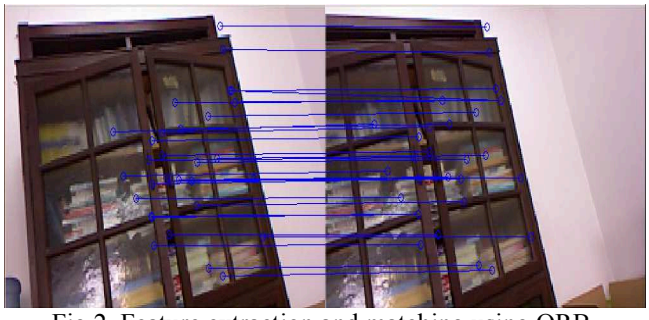

Fig.2. Feature extraction and matching using ORB.

C. Graph-Based SLAM Algorithm

The pairwise transformations between sensor poses form the edges of a pose graph. Due to estimation errors, the edges form no globally consistent trajectory. To create a globally consistent trajectory we optimize the pose graph using the g2o framework [9]. The g2o framework is an easily extensible graph optimizer that can be applied to a wide range of problems including several variants of SLAM and bundle adjustment. It performs a minimization of a non-linear error function that can be represented as a graph.

Experiment Results

We have conducted experiments in our laboratory with the Microsoft Kinect RGB-D sensor. The Kinect uses a structured light for depth information, and its valid range is about 0.5m to 5m. The sensor gives a RGB color image and depth data at 30 frames per second, both with 640 × 480 resolution. The real-time visual SLAM system is implemented on a Intel Core i3-2120 CPU with 4 GB of memory.

Experimental results of the proposed SLAM algorithm are presented in figure 4 and figure 5. Every node of the pose graph has 3D point cloud data which is transformed by the 6-DOF pose of each node and drawn in 3D space. Figure 3(a) shows 3D reconstruction results with only RGB-D data. The estimated sensor trajectory is present with three - dimensional coordinates in figure 3(b).

(a) (b)

Fig.3. Experimental results. (a) 3D reconstruction results with only RGB-D data. (b) Estimated sensor trajectory.

Conclusion

In this paper, we presented a feature-based real-time visual SLAM using sensors such as the Microsoft Kinect. Our approach extracts visual keypoints from the color images and uses the depth images to localize them in 3-D. We use RANSAC to estimate the transformations between associated keypoints and optimize the pose graph using nonlinear optimization. Finally, we generate a 3D reconstruction model of the object and an estimated 3D trajectory of the Kinect style sensor that can be used for robot localization, navigation, and path planning. However, ORB features turn out to be less accurate and also less reliable [10]. In the future, we will try to use GPU-based parallel computing like SIFTGPU [11] and SURFGPU [12] to do the feature extraction procedure and also we will evaluate the 3D estimated trajectory and the 3D model with ground truth data.

Keywords: topology relations; space objects with holes; D9-intersection model; 4-4ID model; HFM model

Abstract. The topology relation is the important basis of GIS data modeling, spatial query, spatial analysis, spatial reasoning and so on. This paper summarizes the current research progress of topological relations between complicated objects (with holes). In accordance with the order of the number of holes, respectively introduce D9-intersection model, 4-4ID model, HFM model and so on, and then analyzes their presentation skills, advantages and defects, so as to provide reference for subsequent research.

Introduction

Spatial relations theories have always been the hot spots of the GIS and related disciplines research at home and abroad [1]. As the most basic spatial relation, topological relations are the research foundation of space analysis [2], topological query [3], spatial reasoning [4] and so on. Currently, many researches focus on the topological relations between simple spatial objects in two-dimensional space and related theories and technologies have been realized by some commercial softwares such as ArcGis, SuperMap etc. Objects that exist in the real world, however, tend to be complex. With the deep and wide application of GIS, existing topological relations theories between simple spatial objects cannot satisfy the current application requirements. Many scholars focus on researching spatial topological relations between objects with holes and hope to provide theoretical basis for the more complicated and deep applications. The purpose of the paper is to summary the existing research results and to compare the advantages and disadvantages of them so as to give reference for the future research.

Topology Relation Mode of Spatial Object with Holes

In the real world, spatial objects are often complicated, such as holes, separate subdivisions and so on. For example, the Italian territory includes several separate islands in addition to the mainland and with a hole (because it is completely surrounded by the Vatican). With the development of GIS application, people play more and more attention on topology relation model for region with holes [5].

2.1 early study for topological relations between areas with hole

In 1994, Egenhofer [6] adopted two concepts which are total region and holes and discussed the relation between two regions with holes. Regions *A* and *B* respectively have *n* and *m* holes, Egenhofer describes the topological relation between them as *A* collection of the following four relations: (1) the total region of *A* and the total region of *B*; (2) the total region of *A* and each hole of *B*; (3) the total region of *B* and each hole of *A*; (4) each hole of *A* and each hole of *B*. Using a *(n+1)*(m+1)* matrix represent the topological relation between two objects, but the problem is that the order of the holes.

Climentini [7] took compound region as the research objects. For two compound regions A and B which respectively contains m and n simple regions, are divided into m+n+2 regions, that is m+n simple regions and two composite regions. In the matrix, the value of position (i,j) is the topological relations between the regions of row i and the column j. The defects of the model is that the matrix can't represent complex regions with holes.

2.2 D9-intersection model

The 9-intersection model has ambiguity when representing the topological relations between complex regions. The model can't distinguish internal complement and external complement as well as internal boundary and external boundary respectively intersect with another region, finally may lead to the same 9-intersection matrix corresponding to a variety of topological relations. The 5 topological relations in Fig.1 are obvious different, for example, but correspond to the same 9-intersection matrix:

$$R_a = R_b = R_c = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}$$

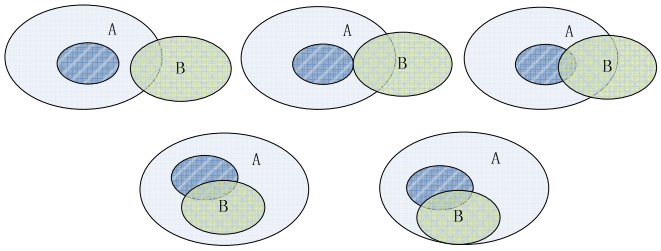

Fig.1 Fuzziness of 9-intersection model (modified from Egenhofer [5]

Against the defect of 9-intersection model, in 2009, OuYang [5] proposed a model that extended 9-intersection model to D9-intersection model. D9-intersection model can express topological relation of region with a hole. In the model, A^o、$\partial_{in}A$、$\partial_{out}A$, A^-,A^h,$\bar{A}$ respectively express the internal, internal boundary (when A with no hole is empty), external boundary, external, hole (when A with no hole is empty), complementary set(as shown in Fig.2). The elements of 9-intersection matrix is extended to binary code, using a five binary code $m_{ij} = x_4\ x_3\ x_2\ x_1\ x_0$, $1 \leqq i, j \leqq 3$, and then transform the binary code into the corresponding decimal number. As the corresponding values of the elements in model, the model can represent the intersection of each part of regions A and B.

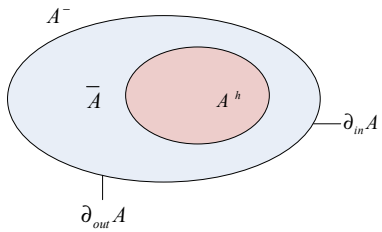

Fig.2 The expression of region with hole in D9-intersection model

Compared with 9-intersection model, D9-intersection model can represent the topological relations between simple regions, as well the topological relations between regions with hole, also will be able to distinguish the topological relations that the 9-intersection model cannot differentiate, so the expression ability of D9-intersection model is stronger than 9-intersection model. But the inference speed of D9-intersection model is relatively lower, memory is relatively large. This model use a five binary code as the values of matrix element, when space complexity of the object increases to a certain extent will go beyond the scope of the code that can be indicial, therefore, there are some shortcomings.

2.3 4-4ID model

In 2009, Liu bo [8] proposed 4-4ID model on the basis of 4-intersection model, the concept of total region and hole in surface object with holes, will define the object with hole as the total region $A^{\#}$ and the hole A^*,and $A^{\#}=A \cup A^*$. For objects with holes A and B, we can determine spatial topological relations between A and B by comparing the relation between t $A^{\#}$, A^*, $B^{\#}$ and B^*, but the model can only describe the topological relations between surface objects with a hole. The equation of 4-4ID model is as following [8]:

$$R(A^{\#},\ B^{\#})=\begin{bmatrix} A^{\#\circ}\bigcap B^{\#\circ} & A^{\#}-B^{\#} \\ B^{\#}-A^{\#} & \partial A^{\#}\bigcap\partial B^{\#} \end{bmatrix} \tag{1}$$

$$R(A^{\#},\ B^{*})=\begin{bmatrix} A^{\#\circ}\bigcap B^{*\circ} & A^{\#}-B^{*} \\ B^{*}-A^{\#} & \partial A^{\#}\bigcap\partial B^{*} \end{bmatrix} \tag{2}$$

$$R(A^{*},\ B^{\#})=\begin{bmatrix} A^{*\circ}\bigcap B^{\#\circ} & A^{*}-B^{\#} \\ B^{\#}-A^{*} & \partial A^{*}\bigcap\partial B^{\#} \end{bmatrix} \tag{3}$$

$$R(A^{*},\ B^{*})=\begin{bmatrix} A^{*\circ}\bigcap B^{*\circ} & A^{*}-B^{*} \\ B^{*}-A^{*} & \partial A^{*}\bigcap\partial B^{*} \end{bmatrix} \tag{4}$$

4-4 ID model effectively represent topology relation between two surface objects which everyone have a hole, but when the model represents topological relations between surface objects with hole, only considering the object with a hole and it can't represents topological relations between surface objects containing 2 and more than 2 holes. More research is needed to find the representation method for topological relations between surface objects with multiple holes.

2.4 HFM model

HFM model proposed by Vasardani [9], which can represent the topological relation between the object with multiple holes and the surface object without hole. HFM model divided an object with multiple holes into complement and some holes, respectively represented by a few simple spatial objects, and then represented the region with multiple holes according to the principle of set theory. Assuming that the region n - B' has n holes, it satisfied with the following conditions [9]:

(1)The union set of n-B, H1… Hn-1, Hn is B. (2) The region B contains Hi, and the values of i is from 1 to n. (3) The region Hi is disjoint to Hj, and the value of i and j is from 1 to n, and that i and j is not equal.

HFM model can represent the topological relations between a simple region *A* and region *n-B'* with multiple holes which is denoted by *r(A, n-B')*. The equation is as following [9]:

$$\begin{aligned} &r(A,n-B^{'})=\bigcup_{i=1}^{n} r(A,B_i),i=1...n,B_i\in t_{RRh} \\ &\forall i:i=1...n,B_i=B-\overline{H_i^{o}} \end{aligned} \tag{5}$$

This model realizes the representation of the topological relation between a simple region and region with multiple holes. Spatial object is not divided into the boundary and interior in this model, so more intuitive when we represent it, but it is unfavorable to distinguish touch and disjoint, and at the same time the hole of complex region has sequential, for the difference of serial number for holes, the representation of topological relations is also different. The efficiency of the model associates with the number of holes in the object, the more holes the objects have, and the lower the efficient is.

Conclusion

Currently, most researches for topological relations are based on 2D spatial object. Proposed D9-intersection model, 4-4ID model and HFM model can preferably represent the topological relations between regions with hole, but these models are also defective. D9-intersection model use a five binary code as the element values in the matrix instead of the nested matrix, the matrix equation is relatively simple, but the complexity of the object is limited. 4-4ID model can only represent the relations between the objects with a hole. HFM model has an advantage over expressing the relation between spatial object with multiple holes and simple object, but the relations which are able to distinguish is limited.

Keywords: Weight Function; Neural Network; Orthogonal; Complexity;

Abstract. Weight function neural network is a new kind of neural network developed in recent years, which has many advantages, such as finding globe minima directly, good performance of generalization, extracting some useful information inherent in the problems and so on. Time complexity is an important measure of algorithm. This paper studies the complexity of neural network using second class orthogonal weight functions. The results indicate that the neural network has a linear relationship with the dimensions of input layer and output layer, an $O(n^3)$ relationship with the number of samples. Finally gives some simulation experiments for time complexity.

Introduction

Weight function neural network is a new kind of neural network developed in recent years, which has many advantages, such as finding globe minima directly, good performance of generalization, extracting some useful information inherent in the problems and so on [1]. For traditional neural networks has many shortcomings, such as slow convergence of the algorithm, the optimal solution can not be obtained, which are to some extent limited the development of neural network. Reference [1] proposed a new learning algorithm to overcome the shortcomings of traditional algorithms in which the constant weight will be transformed into weight function after training, which can effectively reflect implicit valuable information in the sample.

Based on the weight function neural network theory, this paper mainly studies the complexity of second class neural networks using orthogonal weight functions.

Structure of Second Class Weight Function Neural Network

The weight function neural network is a new type of neural network. The input layer connects directly to neurons without any hidden layers. Second class weight function neural network in which input layer has *m* nodes and the output layer has *n* nodes would be like below [1].

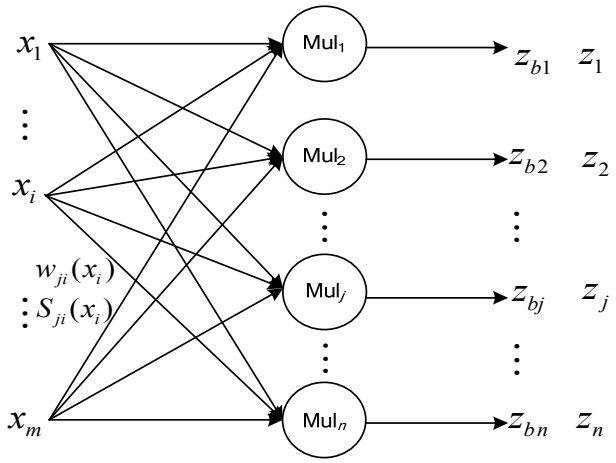

Fig.1. Structure of the weight function neural network

Training weight function neural network is to solve the weight function; the literature [1] gives the training algorithm of how to get the weight function as follows:

Suppose there are *N+2* samples, the corresponding vector of the *i*-th input node which can be expressed as follows:

$$x_i = (x_{i0}, x_{i1}, \cdots, x_{i(N+1)}) \tag{1}$$

Accordingly, the corresponding destination vector can be expressed as follows:

$$z = (z_0, z_1, \cdots, z_{N+1}) \tag{2}$$

In which $z_j\,(j = 0,1,\cdots,N-1)$ is an *n*-dimensional column vector.

According to the literature [1], we can get the corresponding interpolation points:

$$Ip_i = \{(x_{i0}, z_0^{\rho_i}), (x_{i1}, z_1^{\rho_i}), \cdots (x_{i(N+1)}, z_{N+1}^{\rho_i})\} \tag{3}$$

With the interpolation points, approximate weight function can be determined.

Complexity Analysis of the Second Class Weight Function Neural Network

For multidimensional input and output of the second class weight function neural network, it is more complex to analyze the complexity. So only assume one-dimensional output for analysis.

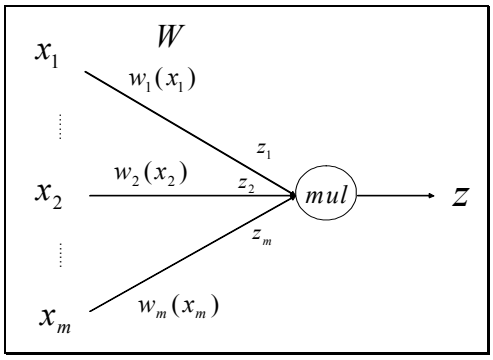

Fig.2. *m* dimension input, 1 dimension output weight function neural network

Assume the number of the training sample is $k+1$, the orthogonal multinomial [2][3] can be constructed as below to approach the weight function:

$$S^*(x) = a_0^* p_0(x) + a_1^* p_1(x) + \cdots + a_k^* p_k(x) \tag{4}$$

In order to facilitate the analysis, just give the $w_1(x_1)$ solving approach, $w_i(x_i)$ are in the same way. According to the weight function neural network training algorithm, $S^*(x)$ has the same value as the weight function at the training samples.

$$\begin{cases} z_{10} = a_0^* p_0(x_{10}) + a_1^* p_1(x_{10}) + \cdots + a_k^* p_k(x_{10}) \\ z_{11} = a_0^* p_0(x_{11}) + a_1^* p_1(x_{11}) + \cdots + a_k^* p_k(x_{11}) \\ \cdots \\ z_{1k} = a_0^* p_0(x_{1k}) + a_1^* p_1(x_{1k}) + \cdots + a_k^* p_k(x_{1k}) \end{cases} \tag{5}$$

The value of $a_0 \cdots a_k$ can be calculated by solving the equation above. Then the approximate orthogonal weight function can be easily determined.

Standard LU decomposition method requires calculating large matrix operation directly [4], involved the calculation of a large amount of data, the computer cache is not well used, and this will reduces efficiency of operation.

LU decomposition needs to solve the linear equations:

$$\mathrm{A}x = b \tag{6}$$

According to the Gaussian elimination rule, after a series elementary row transforming matrix A can be decomposed into plot of the unit lower triangular matrix L and an upper triangular matrix U:

$$\begin{bmatrix} a_{11} a_{12} \cdots a_{1n} \\ a_{21} a_{22} \cdots a_{2n} \\ \vdots \quad \vdots \quad \quad \vdots \\ a_{n1} a_{n2} \cdots a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & & & \\ l_{21} & 1 & & \\ \vdots & \vdots & \ddots & \\ l_{n1} & l_{n2} & \cdots & 1 \end{bmatrix} \begin{bmatrix} u_{11} u_{12} \cdots u_{1n} \\ & u_{22} \cdots u_{2n} \\ & & \ddots \ \vdots \\ & & & u_{nn} \end{bmatrix} or \, \mathrm{A} = LU \tag{7}$$

So equation (6) can be transformed into:

$$LUx = b \tag{8}$$

It is equivalent to two groups trigonometric equations $Ly = b$ and $Ux = y$. According to the matrix multiplication:

$$\begin{cases} u_{1j} = a_{1j} \left(j = 1, 2, \cdots, n \right) \\ l_{i1} = a_{i1} / u_{11} \left(i = 1, 2, \cdots, n \right) \\ u_{kj} = a_{kj} - \sum_{m=1}^{k-1} l_{km} u_{mj} \left(j = k, k+1, \cdots, n \right) \\ l_{ik} = \left(a_{ik} - \sum_{m=1}^{k-1} l_{im} u_{mk} \right) / u_{kk} \left(i = k+1, k+2, \cdots, n; k = 2, 3, \cdots, n \right) \end{cases} \tag{9}$$

Formula (9) is the standard LU decomposition in which needs calculation of a large matrix data. So it has a lower efficiency. In order to solve the problem, now give an introduction to the block LU decomposition algorithm.

Transfer matrix **A** into 2×2 blocks, equation $A = LU$ can be expressed as below:

$$\begin{bmatrix} A_{11} A_{12} \\ A_{21} A_{22} \end{bmatrix} = \begin{bmatrix} L_{11} & \\ L_{21} L_{22} \end{bmatrix} \begin{bmatrix} U_{11} U_{12} \\ & U_{22} \end{bmatrix} \tag{10}$$

According to the matrix multiplication principle：

$$A_{11} = L_{11} U_{11} \tag{11}$$

$$A_{12} = L_{11} U_{12} \tag{12}$$

$$A_{21} = L_{11} U_{12} \tag{13}$$

$$A_{22} = L_{21} U_{12} + L_{22} U_{22} \tag{14}$$

The steps of LU block decomposition algorithm:

1. Make the block matrix A_{11} in formula (11) LU decomposition, get L_{11} and U_{11}.
2. Inverse the matrix L_{11} and formula (12) can be transformed into $U_{12} = L_{11}^{-1} A_{12}$.
3. Inverse the matrix U_{11} and formula (13) can be transformed into $L_{21} = A_{21} U_{11}^{-1}$.
4. Rewrite formula(14), assume $A_{22}^{'} = A_{22} - L_{21} U_{12}$, then formula (14) can be expressed like $A_{22}^{'} = L_{22} U_{22}$.

Make LU decomposition to the matrix $A_{22}^{'}$. As long as the appropriate size of each block is selected, operations of the sub-matrices are more likely calculated in caches which can improve the speed of the algorithm. The multiplication operations of the standard LU decomposition algorithm are about $\frac{n(2n-1)(n-1)}{6}$, division operations are about $\frac{n(n-1)}{2}$.

Conclude that: for *m* dimensional input, one output dimension second class orthogonal function neural network, it needs to solve *m* linear equations. Generally, for *m* dimensional input *n* dimensional output second class orthogonal function neural network, $m \times n$ linear equations need solved. Obviously, the complexity of the algorithm has a linear relationship with input dimensions and output dimensions.

Experiments and Test Results

The purpose of this study was to verify the relationship between the second class orthogonal weight function neural network algorithm complexity and the input layer dimension, output layer dimension, and the number of samples. Experimental operating system: Windows 7. Programming environment: Matlab R2012b.

There are three experiments required to de done:

1. The second type orthogonal weight function neural network algorithm complexity experiments with different sample numbers.
2. The second type orthogonal weight function neural network algorithm complexity experiments with different input layer dimensions.
3. The second type orthogonal weight function neural network algorithm complexity experiments with different output layer dimensions.

And the results are as follows:

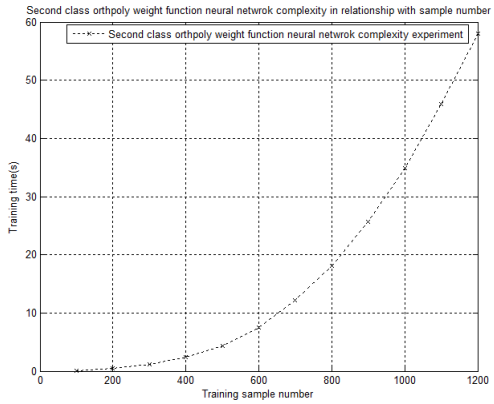

Fig.3. Complexity relationship with sample numbers

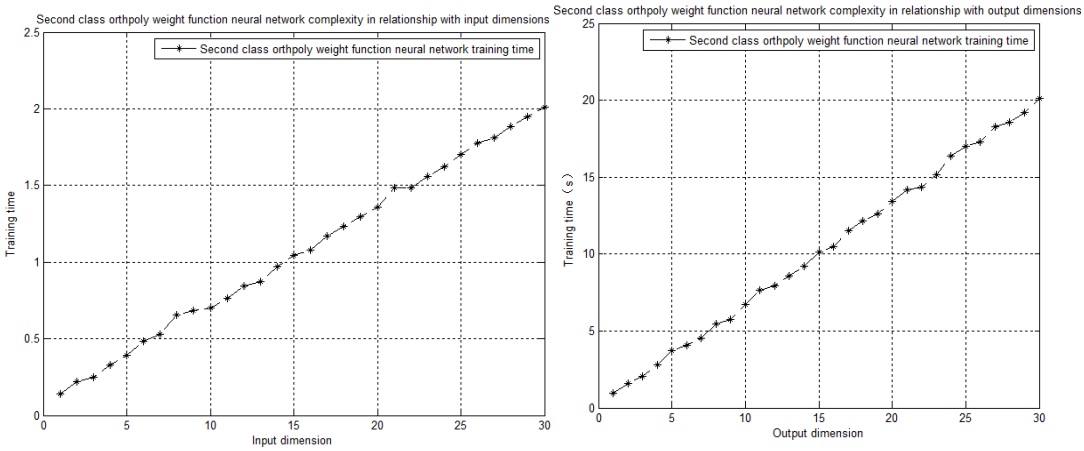

Fig.4. Complexity relationship with input and output dimensions

Keywords: Neural Network; Spline Weight Function; Padé Approximation; Time Complexity;

Abstract. Traditional algorithms of training neural networks have some weakness. A new approach using weight function neural networks was proposed in recent years, which overcomes the shortcomings of traditional neural networks. This paper takes Padé approximation as weight functions and we get the method of how to find the Padé weight functions with given samples. Then complexity is also analysed in detailed in this paper. Finally simulation experiments are done to verify the results.

Introduction

Artificial Neural Network is a kind of advanced computing and pattern recognition technology. It simulates virtual neurons to solve problems in computer applications based on the principle of neural cell in biology. Traditional neural network such as BP, RBF and so on have some weakness. When the network has been trained, the entire network is a connection of discrete numbers, can not reflect the information of samples. Article [1] put forward a new model and algorithm, named weight function neural network. This novel neural network algorithm overcomes the defects above completely [2].

This paper research the time complexity of the first kind of Padé weight function neural networks.

The First Kind of Spline Weight Function Neural Network

Traditional neural networks have shortcomings due to their limitations in the algorithm, but the first kind of spline weight function neural network has many advantages.

Weight function neural network topology structure is simple, only two layers, and the weight of input layer and neurons are full interconnection, while output layer has no weight. Assuming input layer of the network has m nodes，and output layer has n nodes，The structure of the first kind of Padé weight function neural network is shown in the figure below [3] [4] [5]:

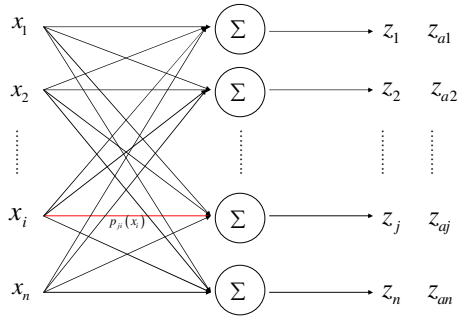

Fig. 1 The structure of the first kind of Padé weight function neural network

Complexity Research of the First Kind of Padé Weight Function Neural Network

Padé approximation of $f(x)$ meet the conditions:

$$\sum_{i=0}^{\infty} c_i x^i - P(M,x)/Q(N,x) = O(x^{\alpha}) \tag{1}$$

$O(x^{\alpha})$ is power function whose format is like $\sum_{i=\alpha}^{\infty} c_i x^i$ .The coefficient of $P(M,x)/Q(N,x)$ is defined as $(m,n)_f$.

When $n \le 4$, it is convenient using the gaussian elimination method compute $P(M,x)$ and $Q(N,x)$ [6].But when n is lager, the calculation is more tedious, not suitable for use [7]. We can use recursive method, Start from $(m_0,n_0)_f,(m_1,n_1)_f \cdots$, which can be easily get. $(m,n)_f$, $(m,n)_f$ can be got from $C-$ chart by recursive using the Padé approximation.

$C-$ chart is a two dimension chart, among them:

$$C(m/n) = \det H(m,n-1,n-1)$$
$$= \det \begin{bmatrix} c_m & c_{m-1} & \cdots & c_{m-n+1} \\ c_{m+1} & c_m & \cdots & c_{m-n+2} \\ \vdots & \cdots & \cdots & \vdots \\ c_{m+n-1} & c_{m+n-2} & \cdots & c_m \end{bmatrix} \tag{2}$$

With the help of $C-$ chart and two of the basic definition, we can get:

$$(m,n)_f = T_n^m (m+1,n-1)_f + (1-T_n^m)(m+1,n)_f,$$
$$T_n^m = \frac{\alpha_{m+1,n}^{m+1}}{\alpha_{m+1,n}^{m+1} - \alpha_{m+1,n-1}^{m+!}} \tag{3}$$
$$(m,n)_f = (m+1,n-1)_f + U_n^m z)m,n-1)_f,$$
$$U_n^m = -\frac{\alpha_{m+1,n-1}^{m+1}}{\alpha_{m,n-1}^{m}} \tag{4}$$

Specific form of algorithm is as follows:

$$\left.\begin{aligned} \frac{\eta_{2j}(z)}{\theta_{2j}(z)} &= \left[\frac{m-j}{j}\right]_f \\ \frac{\eta_{2j+1}(z)}{\theta_{2j+1}(z)} &= \left[\frac{m-j-1}{j}\right]_f \end{aligned}\right\} \tag{5}$$

A recursive according to the formula (3)(4)(5) can get

$$\frac{\eta_{2j}(z)}{\theta_{2j}(z)} = \frac{\eta_{2j-2}(z) - z(\eta_{2j-2}/\eta_{2j-1})\eta_{2j-1(z)}}{\theta_{2j-2}(z) - z(\eta_{2j-2}/\eta_{2j-1})\theta_{2j-1(z)}}, j = 1,2,\cdots m \tag{6}$$

$$\frac{\eta_{2j+1}(z)}{\theta_{2j+1}(z)} = \frac{\left[\bar{\eta}_{2j}\eta_{2j-1}(z) - \bar{\eta}_{2j-1}\eta_{2j}(z)\right]/(\bar{\eta}_{2j} - \bar{\eta}_{2j-1})}{\left[\bar{\eta}_{2j}\theta_{2j-1}(z) - \bar{\eta}_{2j-1}\theta_{2j}(z)\right]/(\bar{\eta}_{2j} - \bar{\eta}_{2j-1})}, j = 1,2,\cdots,m-1 \tag{7}$$

Among $\bar{\eta}_k$ is the coefficient of highest order term of $\eta_k(z)$. Initial values for recursion is

$$\eta_0(z) = \sum_{i=0}^{m} c_i z^i, \eta_1(z) = \sum_{i=0}^{m+1} c_i z^i, \theta_0(z) = \theta_1(z) = 1 \tag{8}$$

Assume the addition operation time is t_1, the subtraction operation time is t_2, multiplication operation time is t_3, Division of time is t_4. The total computation which using the recursive alternating operation is:

$$n\left[(m+n)t_3 + (m+n)t_1\right] + (n-1)\left[2(m+n)t_3 + (m+n)t_1\right]$$
$$\approx n(m+n)(3t_3 + 2t_1) = O(n(m+n)) \tag{9}$$

The reference shows the time complexity of Newton interpolation is $T_{newton} = O\left(N^2\right)$.

Assume that the unit time of operation is as defined above, the training time of the neural network what have m input nodes, n output nodes and $N+1$ training samples is:

$$T = (T_{newton} + T_{pade})mn + mnt_1 = (A + B)mn$$
$$A = O(N^2) \quad (10)$$
$$B = O(\theta(\phi + \theta))$$

Test Results

Determine the input of objective function, set the objective function as follows:

$$z = \sin(x_1 + x_2) \quad (11)$$

To ensure the relationship between the time of the first kind of Padé weight function neural network and the number of samples. Set the number of samples to different values. Different times can be get in these conditions.

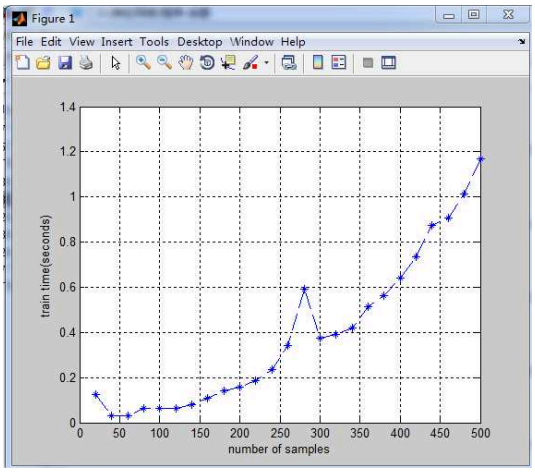

Fig. 2 Time complexity about the first kind of Padé weight function neural network based on the number of samples

To ensure the relationship between the time of first kind of Padé weight function neural network and the number of samples. Set the number of input (output) sample to different values. Different times can be get in these conditions.

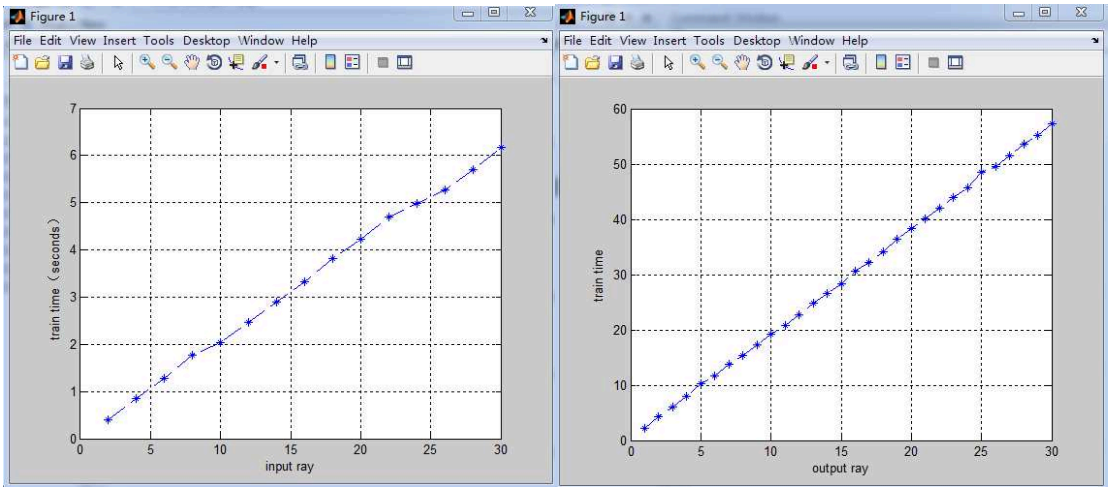

Fig. 3 Time complexity about the first kind of Padé weight function neural network based on the number of input(output) dimensions

Conclusion

This paper analysis the structure and the algorithm of the first kind of Padé weight function neural network, then analysis the corresponding time complexity. Then verify the result by the experiment. The complexity of first kind of Padé weight function neural network is increasing by the number of sample quadric, and growth by the number of input dimension and output dimension liner.

Time Complexity Research on the Second Type Neural Networks of Padé Weight Functions

Daiyuan Zhang[a], Lei Yang[b]

College of Computer, Nanjing University of Posts and Telecommunications, Nanjing, Jiangsu 210003, China

[a]email: dyzhang@njupt.edu.cn, [b]email: yangleiasdz@gmail.com

Keywords: Neural Network; Time Complexity; Padé Weight Function; Newton Interpolation

Abstract. Time complexity is an important measure of algorithm. The main purpose of this paper is to research the time complexity of the second category of Padé weight function neural network and find out the factors which affect its time complexity. In this paper, firstly, the second category of Padé weight function neural network algorithm is introduced. Then through the analysis of the key steps of the algorithm, the time complexity is given. After MATLAB simulation, the experimental results verify the theoretical analysis of the results. Therefore, its time complexity is related to input dimension, output dimension and the number of training samples.

Introduction

From voice recognition software to the car autopilot technology recently, the artificial neural networks have played a huge role. However, the traditional neural network algorithms have many shortcomings. Such as the widely used BP algorithm, with slow convergence, often need to iterate thousands of times. This is also a way to limit the development of neural networks. Literature [1] proposed weight function neural network algorithm, unlike traditional neural networks. Its weight is not a constant, but a function which can reflect the training samples accurately and it's able to overcome the shortcomings of traditional neural networks. The Padé weight function neural network is one of them. This paper has done a detailed analysis of the error formula and the algorithm complexity. Also simulation experiments were done to validate it.

Topology and Training Algorithm of Padé Weight Function Neural Network

The topology of the second type Padé weight function neural network is as follows [1]:

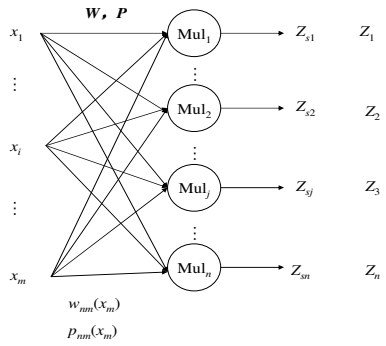

Figure 1 Topology of the second type Padé weight function neural network

Suppose there are *N*+2 samples need to be trained, the corresponding vector of the *i*-th input node which can be expressed as $x_i = \left(x_{i0}, x_{i1}, \cdots, x_{i(N+1)}\right)$. Accordingly, the corresponding destination vector can be expressed as $z = \left(z_0, z_1, \cdots, z_{N+1}\right)$. In which $z_j \left(j = 0,1,\cdots, N-1\right)$ is an n-dimensional column vector. Suppose there are $N+1$ distinct values, such as $x_0, x_1, x_2 \cdots x_N$ and their corresponding function values are $f\left(x_0\right), f\left(x_1\right), f\left(x_2\right), \cdots f\left(x_N\right)$.

With the interpolation points, we can get the Newton interpolation polynomial by using Newton interpolation theory as follows:

$$P_n(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)(x - x_1) + \cdots + a_n(x - x_0)(x - x_1)\cdots(x - x_{n-1}) \tag{1}$$

Because a function of the Taylor series is always with slow convergence speed and narrow convergence range, using this method is sometimes unable to obtain ideal results [2] [3].This time we adopt rational function approximation methods, such as Padé approximation, which tends to get the desired results [4].

Error Analysis

The measure of approximation can be expressed as the following expression [1]:

$$\left\|z_j - z_{jp}\right\| = \left\|\prod_{i=1}^{m} w_{ji}(x_i)\left(1 - \prod_{i=1}^{m}\frac{p_{ji}(x_i)}{w_{ji}(x_i)}\right)\right\| \leq= \kappa_j \cdot m \cdot \left(\prod_{\substack{l=1 \\ l\neq i}}^{m} w_{jl}(x_l)\right) \cdot \left(\max_i \left\|p_{ji}(x_i) - w_{ji}(x_i)\right\|\right) \tag{2}$$

$$\kappa_j = \max\left|-\left(1 + \frac{o(\delta_j)}{\sum_{i=1}^{m}\delta_{ji}(x_i)}\right)\right| = \max\left|1 + \frac{o(\delta_j)}{\sum_{i=1}^{m}\delta_{ji}(x_i)}\right| \tag{3}$$

κ_j is a number close to 1. Next the value of $\left\|p_{ji}(x_i) - w_{ji}(x_i)\right\|$ need to be analyzed, and for convenience, we can use $\left\|p_j(x) - w_j(x)\right\|$ to discuss the value.

$$\left\|w_j(x) - p_j(x)\right\|_\infty = \left\|w_j(x) - H_j(x) + H_j(x) - p_j(x)\right\|_\infty \leq \max_{x\in[x_0,x_n]}\left|w_j(x) - H_j(x)\right| + \max_{x\in[x_0,x_n]}\left|H_j(x) - p_j(x)\right| \tag{4}$$

For the value of $\left\|w_j(x) - H_j(x)\right\|_\infty$, it's known as $\left\|w_j(x) - H_j(x)\right\|_\infty < \frac{c_0 c_1}{n!}$.

And the value of $\left\|H_j(x) - p_j(x)\right\|_\infty$, according to the error formula, can be expressed as follows[5]:

$$H(x) - R_{mn}(x) = \frac{x^{2n+1}\sum_{i=0}^{M} r_i x^i}{Q_n(x)} \approx |r_0|\left|x^{2n+1}\right| \leq |r_0|, \ r_0 = a_{n+1}q_n + a_{n+2}q_{n-1} + \cdots + a_{2n}q_1 + a_{2n+1} \tag{5}$$

$$r_0 = \frac{\Delta_{n+1}}{\Delta_n}, \Delta_n = \det A_n, E_n \approx |r_0| = \left|\frac{\Delta_{n+1}}{\Delta_n}\right|, (|x| \leq 1) \tag{6}$$

Finally, the error formula of the second type Padé weight function neural network is as follows:

$$\left\|z_j - z_{jp}\right\| \leq \kappa_j \cdot m \cdot \left(\prod_{\substack{l=1 \\ l\neq i}}^{m} w_{jl}(x_l)\right) \cdot \left(\max_i \left\|p_{ji}(x_i) - w_{ji}(x_i)\right\|\right) < \kappa_j \cdot m \cdot \left(\prod_{\substack{l=1 \\ l\neq i}}^{m} w_{jl}(x_l)\right)\left(\frac{c_0 c_1}{n!} + E_n\right) \tag{7}$$

Time Complexity Analysis

Recursive method to get Padé approximation needs to use C-list. The so-called C-table, is defined by $C(m/n)$ [5].

$$C(m/n) = \det H(m, n-1, n-1) = \det\begin{bmatrix} c_m & c_{m-1} & \cdots & c_{m-n+1} \\ c_{m+1} & c_m & \cdots & c_{m-n+2} \\ \vdots & \vdots & \cdots & \vdots \\ c_{m+n-1} & c_{m+n-2} & \cdots & c_m \end{bmatrix} \tag{8}$$

The Baker algorithm based on the following two identities.

$$(m,n)_f = T_n^m (m+1,n-1)_f + (1-T_n^m)(m+1,n)_f, (m,n)_f = (m+1,n-1)_f + U_n^m z(m,n-1)_f \quad (9)$$

Where

$$T_n^m = \frac{C((m+1)/(n+1)) \cdot C((m+1)/(n-1))}{C((m+2)/n) \cdot C(m/n)}, \quad U_n^m = -\frac{C(m/(n-1)) \cdot C((m+1)/n)}{C((m+1)/(n-1)) \cdot C(m/n)} \quad (10)$$

Baker algorithm follows the steps:

$$\eta_{2j}(z)/\theta_{2j}(z) = [(m-j)/j]_f, \ \eta_{2j+1}(z)/\theta_{2j+1}(z) = [(m-j-1)/j]_f \quad (11)$$

And then we can get the follows:

$$\frac{\eta_{2j}(z)}{\theta_{2j}(z)} = \frac{\eta_{2j-2}(z) - z(\bar{\eta}_{2j-2}/\bar{\eta}_{2j-1})\eta_{2j-1}(z)}{\theta_{2j-2}(z) - z(\bar{\eta}_{2j-2}/\bar{\eta}_{2j-1})\theta_{2j-1}(z)}, \frac{\eta_{2j+1}(z)}{\theta_{2j+1}(z)} = \frac{[\bar{\eta}_{2j}\eta_{2j-1}(z) - \bar{\eta}_{2j-1}\eta_{2j}(z)]/(\bar{\eta}_{2j} - \bar{\eta}_{2j-1})}{[\bar{\eta}_{2j}\theta_{2j-1}(z) - \bar{\eta}_{2j-1}\theta_{2j}(z)]/(\bar{\eta}_{2j} - \bar{\eta}_{2j-1})} \quad (12)$$

Where $\bar{\eta}_k$ is the coefficient of the highest degree of $\eta_k(z)$, and initial value is $\eta_0(z) = \sum_{i=0}^{m} c_i z^i$, $\eta_1(z) = \sum_{i=0}^{m+1} c_i z^i$, $\theta_0(z) = \theta_1(z) = 1$. Using $[m+n,0]_f$, $[m+n-1,0]_f$ as the initial value to calculate is a very convenient and efficient way; and the total time needed is approximately:

$$n[(m+n)T_2 + (m+n)T_1] + (n-1)[2(m+n)T_2 + (m+n)T_1] \approx n(m+n)(3T_2 + 2T_1) = O(n(m+n)) \quad (13)$$

So by the recursive method to get the Padé approximation $P_L(x)/Q_M(x)$ of $f(x)$, The time complexity is $O(M(L+M))$, where L is the highest degree of $P_L(x)$ and M is the highest degree of $Q_M(x)$.Because that Training samples is N, there are N sample interpolation points and the time needed to get the Newton polynomial is $N(N-1)T_1 + \frac{N(N-1)}{2}T_2$.

The time of the recursive method to get the Padé approximation $P_L(x)/Q_M(x)$ of $f(x)$ is $M(L+M)(3T_2+2T_1)$ where L is the highest degree of $P_L(x)$ and M is the highest degree of $Q_M(x)$.Then we get the time of solving $m \times n$ Padé weight functions is

$$mn[N(N-1)T_1 + \frac{N(N-1)}{2}T_2 + M(L+M)(3T_2+2T_1)] \quad (14)$$

And its time complexity can be expressed as $mnO(N^2)$, where m is the input dimension, n is the output dimension, N is the number of samples.

Experiments and Results

There are four experiments required to de done to verify the error formula and the relationship between the algorithm complexity and the input layer dimension, output layer dimension, and the number of samples. Experimental operating system: Windows 7. Programming environment: Matlab R2012a.

And the results are as follows:

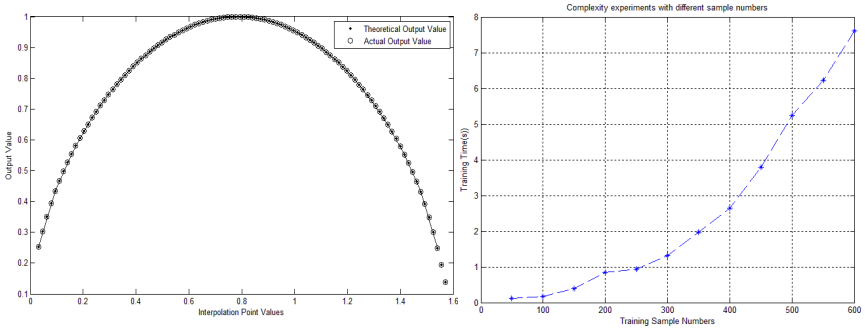

Figure 2 Error experiments and Complexity experiments with different sample numbers

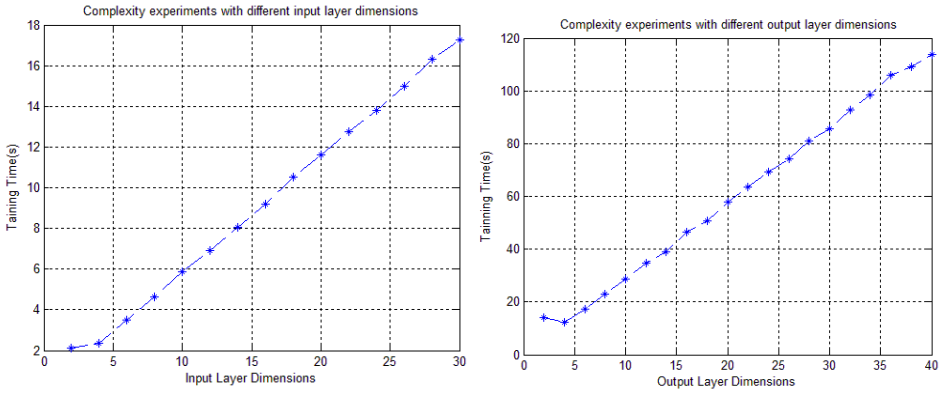

Figure 3 Complexity experiments with different input layer and output layer dimensions

Conclusion

In this paper, through theoretical analysis and experimental verification, it shows the algorithm complexity of the second type Padé weight function neural network is $mnO(N^2)$.Where m is the input dimension, n is the output dimension, N is the number of samples. And in solving problems which has complex topology, this algorithm take less time to be trained, and it has obvious advantages.

Keywords: Air traffic control; Neural network; RBF; Air traffic management; Safety assessment

Abstract. To assess the safety situation in air traffic control effectively, a comprehensive assessment method based on RBF neural network is proposed. At first, the safety assessment principle based on RBF neural network is introduced, and then the safety assessment index system for air traffic control is established from four aspects of human, machine, environment and management. Simulation example of ATC safety assessment gives us a satisfactory result for RBF neural network.

Introduction

In recent years, many developed countries pay more and more attention to systemic safety management of civil aviation, namely prevent the occurrence of accidents by means of risk management on the basis of original safety management mode [1]. So it is important to study the system safety assessment method for improving the safety level of air traffic system, it can provide the premise and basis for the ATC safety management, and is also a powerful guarantee to realize the higher safety goal of ATM [2].

At present, in my civil aviation, the actual safety assessment work for air traffic control system basically use the qualitative analysis and assessment method. It is mainly carry out the qualitative analysis to the state of equipment, facility, environment, personnel and management and so on in air traffic control system according to the experience and intuitive judgment [3][4]. The assessment results are some qualitative indexes such as whether achieving a certain safety index, accident categories and accident inducement factor and so on, which cannot perform the quantificational, dynamic description to system safety situation. Theoretical study mainly has the following problems: the foreign safety assessment system is not suitable for china; there exist the difference between the assessment model and the actual problem; the built model only remains at the static assessment level.

Based on it, RBF neural network is introduced to study its application in ATC for establishment of safety assessment model. The simulation validates its feasibility.

Safety assessment principle based on RBF neural network

RBF neural network has the accurate mapping ability to the nonlinear problem, and presents the excellent function approximation capability with simple structure and fast learning speed without the complex system modeling process. It is able to learn the rules and laws hidden in sample data, and accurately determine the mapping relationship between input data and targets, building a qualitative and quantitative comprehensive assessment model closer to human thinking mode [5][6]. The safety assessment process based on RBF neural network is shown in Fig. 1 [7].

In the trained RBF neural network, the connection weight of network denotes the assessment idea of expert, which can not only simulate the experts to quantitatively assess, but also avoid human error in the assessment process. Since the connection weights of model are obtained by learning from examples, which avoids the subjective effects and uncertainty that the connection weights and correlative coefficients are artificially calculated. RBF neural network is of special significance for the prediction. We can predict the future trend of the ATC safety risk according to the trend curve, which has a certain role in constitution of safety policy, adoption of safety measures, and so on.

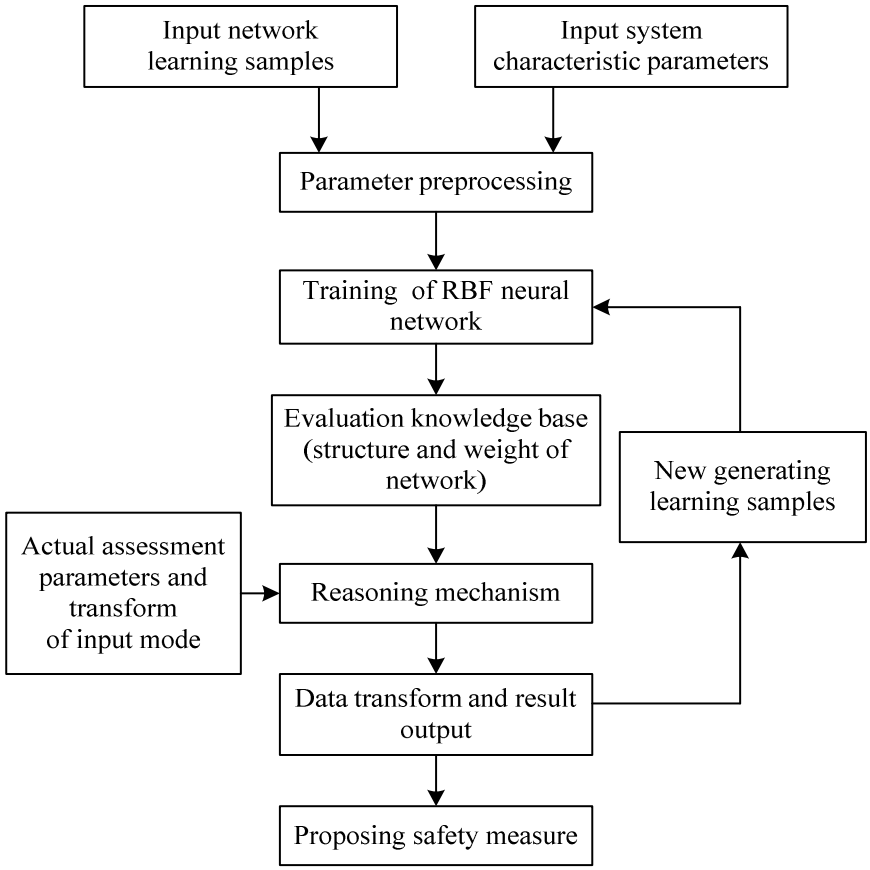

Fig. 1 Flowchart of safety assessment based on RBF neural network

Establishment on safety assessment index system for air traffic control

Air traffic system operation involves the personnel and facilities of many departments, and the harmonious operations between these departments must rely on scientific management. In China, the airspace is more complex things, the development between East and West is unbalanced, the difference of communication, navigation, surveillance facilities is very large, the various ways such as radar control, program control under radar surveillance, program control and so on coexist. Air traffic system is a dynamic system with the feature of continuous time, wide space, too many constituent elements, complex relationships, high safety probability requirements. In view of the characteristics of the system and the dependence on management, according to system engineering theory, we adopt the system comprehensive assessment method base on human-machine-environment-management factor. The safety status of the air traffic control system can be obtain by integrating the safety status of four subsystems, and the safety status of each subsystem can be obtain by integrating the safety status of a number of factor in each subsystem [7]. The safety of each underlying factor is generally given by according to experience and knowledge of experts as shown in Fig. 2.

Simulation example

For ATC safety assessment, the collected sample data should reflect its internal law as far as possible, and adequately consider the own characteristics of network. The paper is based on an ATC database and combined with rich expert experience and profound professional technology to mark for determination of network weight vector and identification of ATC safety state. Experts are mainly from approach control room, tower control room, area control room, flight services room, technical support section, network equipment room, ATC radar room, safety supervision department and so on. The test samples and the training samples are obtained by questionnaire analysis. Each sample data record the assessment information that reflects the safety degree of ATM. each safety assessment

includes the score about 24 safety factors with score range [0,10], and need to conduct the normalization before modeling. Tabel 1 gives the standard output modes of network

The training samples are inputted to train RBF neural network by adjustment of the parameters, obtaining the safety assessment model for ATC. Inputting 8 test samples, we can obtain the test results as shown in Table 2. It can be seen that the results the test results are fully consistent with the actual results within acceptable error limits.

Poor	0.00	0.00	0.00	1.00	0.00
Very poor	0.00	0.00	0.00	0.00	1.00

Tabel 2 Comparison between test results and actual results

Number	Out of wavelet neural network					Actual assessment value				
1	0.001	0.840	0.011	0.108	0.090	0.00	1.00	0.00	0.00	0.00
2	0.975	0.003	0.202	0.001	0.029	1.00	0.00	0.00	0.00	0.00
3	0.007	0.001	0.056	0.902	0.002	0.00	0.00	0.00	1.00	0.00
4	0.014	0.006	0.890	0.011	0.023	0.00	0.00	1.00	0.00	0.00
5	0.959	0.008	0.002	0.005	0.030	1.00	0.00	0.00	0.00	0.00
6	0.068	0.011	0.004	0.901	0.002	0.00	0.00	0.00	1.00	0.00
7	0.002	0.938	0.008	0.026	0.003	0.00	1.00	0.00	0.00	0.00
8	0.034	0.007	0.001	0.002	0.829	0.00	0.00	0.00	0.00	1.00

Conclusions

A safety comprehensive assessment method based on RBF neural network for ATC is proposed. In the method, the connection weight of RBF neural network is used to dynamically express the assessment information of experts. It can not only quantitatively describe the suggestion of expert, but also avoid the addition of human error in the process. Simulation gives a good validation for the proposed ATC safety comprehensive assessment method.

Keywords: Highway; Safety Facilities; Ant Colony Optimization; Neural Network

Abstract. Highway traffic safety facilities system evaluation plays an important role to relieve highway safety problem. From the perspective of system engineering, the influence factors of the current situation are comprehensively considered, the freeway traffic safety facilities system evaluation index system is established, and the application of ant colony neural network evaluation model is constructed. The purpose is to provide the beneficial references for freeway traffic safety facilities system evaluation.

Introduction

Highway traffic safety facilities system includes road traffic guardrails, signs, marking, isolation facilities and bridges retainer, anti-dazzle facility, sight induced facilities, etc. They are used to reduce the severity of the accident, eliminate various longitudinal and transversal interference, improve the road service level, and provide the view induction. They also play an important role in improving road landscape, especially having the special significance to give full play to the function of road safety, rapidness, economy and comfort. [1][2]The existing traffic safety evaluation method in the practical application is short of autonomous learning ability, and it is hard to get rid of randomness, subjective uncertainty and fuzziness of knowledge in the process of evaluation, so it is limited in a lot of practical application. Therefore, it is necessary to choose the more effective evaluation method of highway traffic safety facilities system to apply for the practical situation.

Neural Network Based on Ant Colony Optimization

Back Propagation Neural Network

In recent years, BP (Back Propagation) neural network is widely used in modeling, pattern recognition and control, time series analysis and evaluation, and it has achieved good effect. BP network is a typical multilayer network, its topological structures include input layer, hidden layer and output layer. It adopts full connection between layer and layer, as shown in figure 1. Practical application shows that the BP network has strong ability of mapping. The training process of BP optimization includes two processes, which are forward spread of signal and backward spread of error. On the one hand, forward spread the afferent input samples from the input layer, after each of them processed step by step in a hidden layer, then transferred to output layer. If the actual output is different with the expected output of output layer, then start the error back propagation phase. On the other hand, error back propagation is that the output error transferred to the input layer step by step in some way through the hidden layer, then the error is distributed to all elements of each layer to get error signal of each unit, and the error signal is used as the basis for correcting the weights of each unit. Each layer weights adjustment based on signal's forward spread and error's back propagation iteration process is constantly repeated. Weights are constantly adjusted, which is also known as the training process of the network. This process does not stop until the precision of the network output error has reduced to allow number, or to the pre-set number of learning so far. After

getting the appropriate network connection value, nonlinear image can be used for the new samples.[3][4]

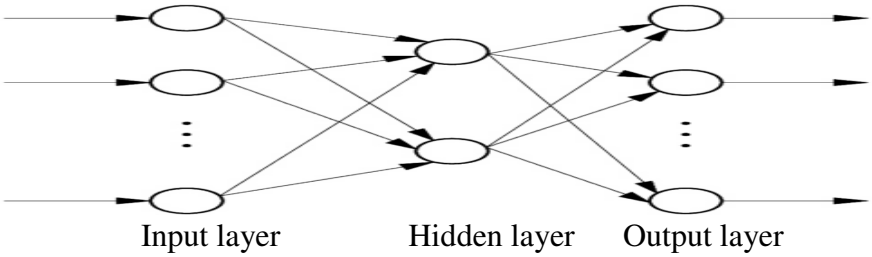

Figure 1 Three-layer BP Network Topology

Ant Colony Optimization

Ant Colony Optimization (the ACO) is a kind of probability algorithm used to find the optimal path in the diagram. This optimization is proposed by Italian scholars Dorigo. M at the first European artificial life meeting held in Paris, France, in 1991. He was inspired by the real ant group of crowd behavior of searching for food. Ants start from nest to food source, and randomly select any path that can arrive at the food source. They release a pheromone at the same time after passing through this path, so that they can communicate with other ants in ant colony coordination. Subsequent ants determine which path to choose in next step according to the pheromone concentration of each path, and eventually achieve the optimal solution. The optimization has some major advantages to find the optimal solution quickly. It has optimal benign of distributed computing mechanism, and can easily combine with other methods. This method is mainly to solve the combinatorial optimization problems, and is able to achieve good results as expected.

Neural Network Training Based on the Ant Colony Optimization

The weights of the neural circuits are trained by using global optimization and heuristic optimization features of ant colony optimization in order to avoid the defects of BP neural network. The basic idea is that it is supposed that parameters number in the network is f, and the parameters include ownership value and threshold. After being sorted, these parameters Pi (I is between 1 and f)are set to N random non-zero values in the neural network, and they parameters form the set Upi. Each ant of the ant colony selects a value, and then chooses a set of the weights of neural network. The number of ants is g, τj means the pheromone of the first j element Pj. When the ant is searching, different ants were independent of each other. Each ant starts from the collection of Upi, and then chooses one element from each set Upi according to the pheromones and state transition probability in the collection. When ants complete the choice of elements in full set to, it will reach the food source, and return to the nest along the path just walked, and then adjust the information in the collection. Finally after repeated processes of the ants until the evolution trend is not obvious or a given number of iterations has finished, the optimal solution of parameters can be found.

The improved specific steps of ant colony optimization are as follows:

1) Initialization. Make the time t, and cycles Nc are zero, set the maximum cycles is Ncmax, make the pheromone τj(Upi) = C and τj(Upi) = 0, the pheromone belongs to each element in the set, and put all the ants in the nest.

2) Start all ants k (k = 1, 2,..., g), as for Upi, calculate the state transition probability according to the following formula:

$$p_r(\tau_j^k(U_{pi})) = \frac{\tau_j^k(U_{pi})}{\sum_{i=1}^{N} t_j(U_{pi})} \quad (1)$$

3) Repeat step 2 until the ant colony has reached the food source.

4) Make t to t + f, Nc to Nc + 1, calculate the output value and error of the neural network according to the selection weight of each ant, and record the current optimal solution. After unit

time of f, each ant reaches food source from the nest, each path pheromone was updated according to the following formula:

$$\tau_j(U_{pi})(t+f) = (1-\rho)\tau_j(U_{pi})(t) + \Delta\tau_j(U_{pi}) \quad (2)$$

$$\Delta\tau_j(U_{pi}) = \sum_{k=1}^{g} \Delta\tau_j^k(U_{pi}) \quad (3)$$

$$\Delta\tau_j^k(U_{pi}) = \begin{cases} \frac{Q}{\varepsilon^k} \\ 0 \end{cases} \quad (4)$$

5) When the ant colony all converge to a path or cycle number of Nc reaches Ncmax, the cycle is finished, and output the results; Otherwise, skip to step 2.

Highway traffic Safety Facilities System Evaluation Model and Algorithm

Modeling Ideas Based on Ant Colony Optimization and Neural Network

BP neural network has strong nonlinear mapping ability and the generalization capability, but it is easily trapped in local minima and has slow convergence speed. In order to solve that problem, this paper uses ant colony algorithm for training neural network and puts forward security evaluation model on the basis of neural network. The modeling idea is as follows: Firstly, fuzzy the collected data, then make them as the input and output of feed forward neural networks. Secondly, train the network with rapid global convergence of the ant colony algorithm with BP algorithm; lastly, get the nonlinear mapping model between the raw data and the level. A three-layer BP model of highway safety facilities evaluation prediction is established. The first layer is the input layer, and it has 15 neurons worked as the evaluation index which is shown in table 1[5]. The second layer is the hidden layer. The third layer is the output layer, in which there are five neurons as the safety evaluation rank. Dividing a score as follows: y1 is level Ⅰ meaning "safety" (00001); Y2 is level Ⅱ meaning "safer " (00010); Y3 is level Ⅲ meaning "general safety" (00100); Y4 is level Ⅳ meaning "unsafe" (01000); Y5 is level Ⅴ meaning "very unsafe".

Table 1 Evaluation Index of Highway Traffic Safety Facilities System

The Serial Number	Evaluation Index
X1	Roadside safety net area
X2	Crashworthiness of guardrail
X3	The rationality of guardrail end processing
X4	Guidance of guardrail
X5	Information readiness
X6	Usage of breakaway traffic sign
X7	Durability of the marking
X8	Sliding resistance of marking
X9	Height of isolation facilities
X10	Stability of isolation facilities
X11	Continuity of isolation facilities
X12	Shielding angle of anti-dazzle facility
X13	Height of anti-dazzle facility
X14	Function of sight guidance facility
X15	Rationality of emergency lane

Implementation Steps of Algorithm

Implementation process of highway safety facilities evaluation model algorithm is as follows:

(1) Determine the objective function, using least squares objective function, namely

$$f(x) = \sum_{i=1}^{n} (O_i^c - O_i^m)^2 \quad (6)$$

In the formula: n represents for test group; O_i^c is the real output of the ith group test; O_i^m is the expected output of group I test.

(2) Get the sample set of neural network by collecting the data, and the samples are normalization processed.

(3) Neural network learning Using ant colony algorithm to learn the weights of neural network to establish evaluation index and nonlinear mapping of grade for highway safety facilities, eventually get evaluation model for highway safety facilities.

Conclusion

Highway traffic safety facilities system plays the role through the coordination of the whole system. System engineering ideas and methods is useful for the evaluation research of highway traffic safety facilities system. Only in this way the role of highway safety facilities can be fully and fairly evaluated, and guide the similar safety facilities system planning, design, construction and maintenance management. Since research time is limited, this paper carries on the preliminary study only based on ant colony neural network evaluation method, and evaluation results and the suggestion remains to be further validated by Matlab model.

Keywords: Physical Chemistry; Passive RDX; Heating rate; Charge density; Numerical simulation

Abstract. For passive RDX, fluent software was applied to simulate the cook-off for explosive of different charge density at heating rates of 1, 5, 10k/min to improve thermal safety in the ammunition storage, transport and battle. The results show that the heating rate has great effect on ignition time and position for passive RDX. Charge density also has great influence on ignition time but no influence on ignition position. The ignition time decreases and ignition position moves from the center to the two ends of the cylinder edge with the increase of the heating rate. The ignition time increases with the increase of charge density under the same condition. Therefore, increasing the charge density can effectively improve the thermal safety of ammunition.

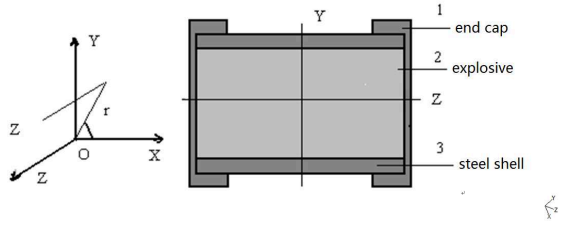
Introduction

In the modern war，with the changing of battlefield environment, thermal safety of ammunition in storage, transportation and operation has attract more and more attention from many countries. The cook-off test is one of the important methods to test and evaluate the thermal safety. At present, Cook-off experiments and numerical simulation are two ways to study cook-off phenomenon of explosive. Although cook-off test can effectively evaluate thermal safety of explosive, but it has high cost and long research cycle and it is difficult to get system comprehensive measurement dates. Numerical calculation can easily change cook-off conditions such as heating rate, charge density, charge size and so on. The result of numerical simulation is forward-looking, it can predict law of explosive ignition. In 1991, Jones et al[2] carried out one-dimensional numerical calculation for small cook-off bomb (SCB) experiment by HEAT software developed with Fortran language. Since then, a lot of cook-off numerical simulation had been conducted. Feng Chang-gen et al[3]performed numerical simulation for cook-off process of RDX under different ambient temperature. Wang pei et al[4] performed a three-dimensional numerical calculation on GHL at different heating rates. A composite charge structure had been investigated numerically and experimentally by Xiang mei al[5].They found that embedded high-energy grain in insensitive explosive can effective improve its thermal safety.

In this paper, taking passive RDX as research object, a three dimensional calculation model was established to simulated cook-off phenomenon of different charge density passive RDX under three heating rates. The effect of heating rate and charge density on cook-off characteristics has been investigated to provide technical support for explosives in the thermal safety.

The numerical calculation model

Cook-off process includes four stages: flame combustion, explosive heating, shell response, explosive violent reaction. This paper only simulated heating process of explosive. Physical model of passive RDX is shown in figure 1. In the model, the explosive charge diameter is 17mm, the cylinder length is 28mm, the steel shell thickness is 3mm, upper and bottom ends thickness is 1mm. In order to decrease calculation magnitude to save calculation time, built 1/2 normal cylinder numerical simulation model, namely the section above the Z-axis. The requirement of calculation for heat transfer is not high, so the model can chooses a hybrid grid, as shown in figure 2.



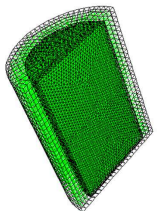


Figure 1 Physical model of cook-off bomb Figure 2 Calculation grid of model

In calculation, making the following assumption for cook-off process of passive RDX:

1) Explosive is homogeneous phase, chemical reaction is zero order exothermic reaction, explosive phase change does not occur, no consumption of reactants;

2）It is assumed that reaction zone only have heat conduction, reactive material remain without motion, therefore there is no convective heat transfer.

3）The thermal action process of explosive is unsteady heat conduction.

4）The reaction zone boundary is impermeable to material, the heat exchange at boundary obey Newton's law of cooling

5) The physical and chemical parameters remain unchanged in the reaction process.

Thermal reaction and thermal conduction follow the Frank-Kamenetskii equation [6]:

$$\rho c_v \frac{\partial T}{\partial t} = \lambda \nabla^2 T + Q\rho aA \exp(-\frac{E}{RT}) \quad (1)$$

In cylindrical coordinates, the temperature field control equation can be expressed as:

$$\rho c_v \frac{\partial T}{\partial t} = \lambda \left(\frac{\partial^2 T}{\partial r^2} + r\frac{\partial T}{\partial r} + \frac{1}{r^2}\frac{\partial^2 T}{\partial \varphi^2} + \frac{\partial^2 T}{\partial z^2} \right) + QaA \exp(-\frac{E}{RT}) \quad (2)$$

Where ρ, C_V, λ, a respectively denotes the reactant density (kg/m3), specific heat capacity (J/kgK), thermal conductivity (J/mKs) and reaction scores. Q is the reaction heat of reactant （J/kg）, A refes to former factor(1/s), E is activation energy（J/mol）, R is gas constant（J/molK）.

The shell outside wall is set as heating boundary. Initial ambient temperature is 306.5K. Selecting three kinds of heating rates which is 1, 5, 10k/min. Then the plans that charge densities are 70%,75%,80%,85%,90% of theoretical maximum density are simulated at each heating rate. CFD software was applied to simulate the model above. Chemical reaction heat release item of explosive was embedded into main program by text. About physical and chemical parameter of passive RDX, this study used the material parameter of literature 7, as shown in table 1.

Table.1 The parameters of the simulation model material

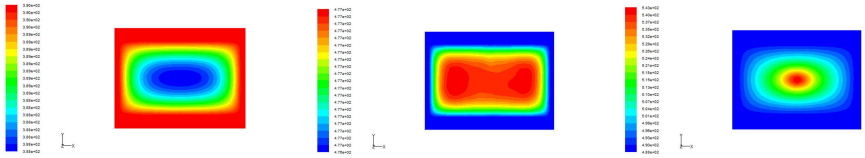
parameter	Passive RDX	45steel shell
density（kg/m3）	1640	7850
specific heat capacity(J/kgK)	1130	480
thermal conductivity (J/mKs)	0.213	43
reaction heat (J/kg)	2.101×10^5	---
former factor (1/s)	2.01×10^{18}	---
activation energy (J/mol)	202730	---
gas constant (J/molK)	8.314	---

The analysis of cook-off characteristic at different heating rates

To analyzes the cook-off characteristics of passive RDX at different heating rates, the temperature distribution on a longitudinal cross-section of cook-off bomb at each time is compared. The charge density is 80% of theoretical maximum density.

Figure 3 shows temperature distribution on cook-off bomb at each time under heating rate of 1K/min. At a time of 5000s, the heat provided by external heat source transfer to explosive cylinder, then the temperature on outer edge of explosive cylinder begin to rise gradually, but the temperature

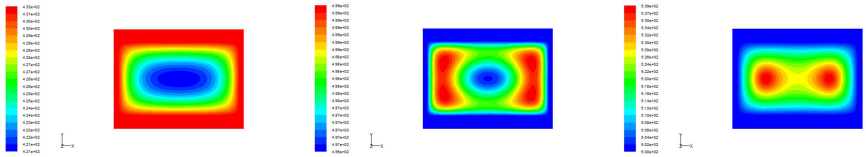
inside explosive changes little. Later, at 10200s, thermal decomposition inside explosive produce large quantities of heat, and it is too late to realease the heat to surrounding, resulting in rapid rise of temperature on intermediate region. The high temperature region like a cylinder appeared at the center, becoming smaller with the increasing of time. When time reaches 10870s, the high temperature region has become an small ellipse distribution and the temperature reached ignition temperature. The ignition temperature is 543K.



5000s 10200s 10870s

Figure 3 Temperature distributions on cook-off bomb at each time under heating rate of 1k/min

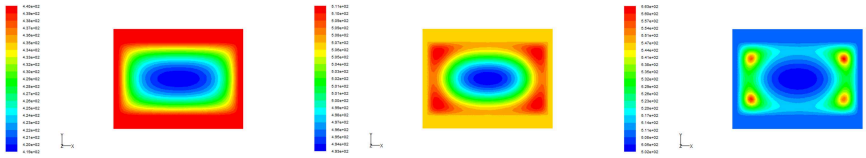
Figure 4 shows temperature distribution on cook-off bomb at each time under heating rate of 5K/min. The temperature changes at this heating rate which is different from the fomer. At a time of 1500s, the temperature on outer edge of explosive cylinder began to rise gradually, but the temperature inside explosive changed little. At 2280s, the high temperature region appears at edge of two ends of explosive cylinder cross with cap. At the time of 2300s, as heat transfers from external heat source and thermal decomposes inside explosive, the high temperature region moves to center of explosive. The high temperature region seems a double funnel in explosives. When time reaches 2324s, the temperature reaches ignition temperature and the ignition temperature is 539K.



1500s 2280s 2324s

Figure 4 Temperature distributions on cook-off bomb at each time under heating rate of 5k/min

Figure 5 shows temperature distribution on cook-off bomb at each time under heating rate of 10k/min. At 800s, the temperature at the center of explosive is higher than that at the surface of explosive. At the time of 1200s, due to the heating rate is too fast, thermal decomposition inside explosive produce large quantities of heat, and it is too late to realease the heat to surrounding, then the temperature around explosive and two end caps rises rapidly which formed high temperature region. When time reaches 1218s, the temperature reaches ignition temperature and the ignition temperature is 543K.



800s 1200s 1218s

Figure 5 Temperature distributions on cook-off bomb at each time under heating rate of 10k/min

Figure 6 shows variations in ignition time, ignition temperature and shell temperature with heating rates for cook-off bomb. The charge density is 80% of theoretical maximum density. It can be seen that heating rate have little effect on ignition temperature, all the ignition temperatures are about 540K. The ignition time decreases with increasing of heating rate, for example, the ignition time is 10870s at heating rate of 1k/min，but decreases to 1218s at heating rate of 10k/min, the time reduced by a factor of 10. The shell temperature increases with increasing of heating rate, the shell temperature is 488k at heating rate of 1k/min, and increases to 511k at heating rate of 10k/min. It indicates that lower heating rate lead to a lower ambient temperature. It is more dangerous under lower heating rate.

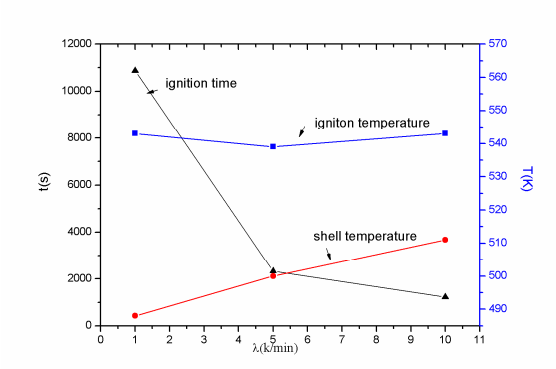


Figure 6 Ignition time, ignition temperature and shell temperature as a function of heating rate

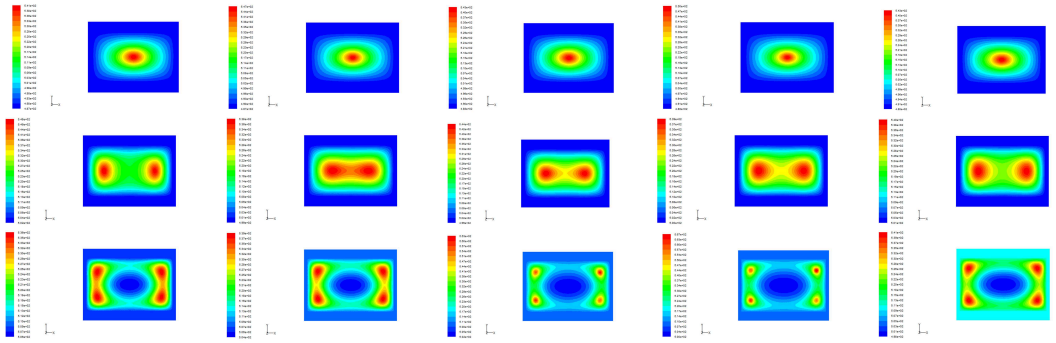
The analysis of cook-off characteristic at different charge densities

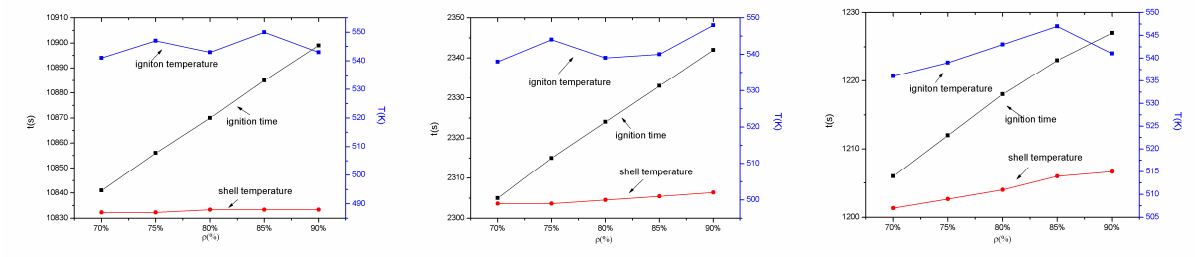
A comparison in ignition position for different charge densities under three heating rates is shown in figure 7. It is apparent that the ignition position does not change with variation of charge density.



70% 75% 80% 85% 90%

Figure 7 Influence of charge density on ignition position under three heating rates

Figure 8 shows variations in ignition time, ignition temperature and shell temperature with charge density under three heating rates for cook-off bomb. Fig (a), (b) and (c) indicate that charge density has little influence on ignition temperature, all of them for five charge densities are about 540K. The ignition time increase with increasing of charge density, and the growth rate of ignition time remain basically unchanged which means the relationship between ignition time and charge density is linear increasing. Therefore, the higher charge density of cook-off bomb is, the higher thermal safety would be. The cause of the relationship is that as the charge density increase, the porosities of explosive cylinder become smaller, hot spots become less, resulting in decreasing of temperature and the reaction rate decreases, thus the time from heating to ignition becomes longer [8]. In addition, the shell temperature also has a rising trend when explosive ignite with increasing of charge density, which indicates lower charge density lead to a lower ambient temperature. It is more dangerous under lower charge density.



(a)1k/min (b)5k/min (c)10k/min

Figure 8 Variation in cook-off characteristics with charge density under three heating rates

Conclusions

(1)Heating rate have great effect on ignition time and ignition position, but have little effect on ignition temperature. When the heating rate is low, the ignition position locate at the center of explosive cylinder , then as the heating rate increase, the ignition time become longer, and ignition position moves from the center to the two ends of the cylinder edge

(2)Charge density has little effect on ignition position and ignition temperature. Increasing charge density can effective increases the ignition time or improve thermal safety of explosive.

(3)In this paper, the calculation results can reflect the basic characteristics of cook-off, thus it can provide a reference for numerical simulation and experimental research of cook-off in the future. But because of lacking available experimental dates, the accuracy of the calculation results remains to be verified.

Keywords: Traffic flow, Prediction, Fuzzy neural network

Abstract. Many machine learning approaches in the field of Artificial Intelligence (AI) have been developed. Most of them rely on using large data sets to build up knowledge. However, the traffic system usually has only few data. In this article, the so-called adaptive neural fuzzy inference systems (ANFIS) is employed to predict the traffic time-series with few data, including flow, speed and occupancy

Introduction

With the development of economy and society, the number of cars in urban is increasing at an astonishing rate. Road construction lags behind the fast increase of vehicles, which makes the traffic capacity provided by road traffic facilities cannot meet the need of current traffic. Traffic congestion has already become the main problem in the cities, and it may become the bottleneck of further development of economy if it continues to worsen. Intelligent Transportation Systems (ITS) are considered to be a solution for traffic congestion problems. One of the ways of alleviating the congestion problems is to redistribute the traffic over the highway network. This redistribution can be spatial as well as temporal. If travelers have advanced information about the traffic conditions, they can reschedule their trips. One of the important issues in an Advance Traveler Information System (ATIS) is accurate forecasting of traffic conditions in the short-term future.

The complexity and uncertainty of traffic flow make it difficult to predict. In the past studies, experts and scholars have proposed a lot of methods and techniques, such as nonparametric regression method[1], chaotic time series method[2], neural network[3], Grey GM(1,1)[4], Kalman filter[5], multivariate state space approach[6], ARIMA[7], fuzzy-neural approach[8], support vector regression [9] and combined method[10], which have been used to forecast traffic volumes. However, there is no single method had yet been developed that presented itself to be universally accepted as the best and effective traffic flow forecasting model.

In this paper, the method called Adaptive Neural Fuzzy Inference Systems (ANFIS) is used to predict the traffic time-series, which has used to predicting the chaotic time-series successfully [11]. A hybrid learning algorithm is used to identify parameters of Sugeno-type fuzzy inference systems. And the least-squares method and the back propagation gradient descent method are combinationed to train the FIS membership function parameters.

The paper is organized as follows. The ANFIS model is introduced in Section 2. The experiments on traffic time-series prediction problems are given in Section3. And the results are discussed in Section 4.

ANFIS Model

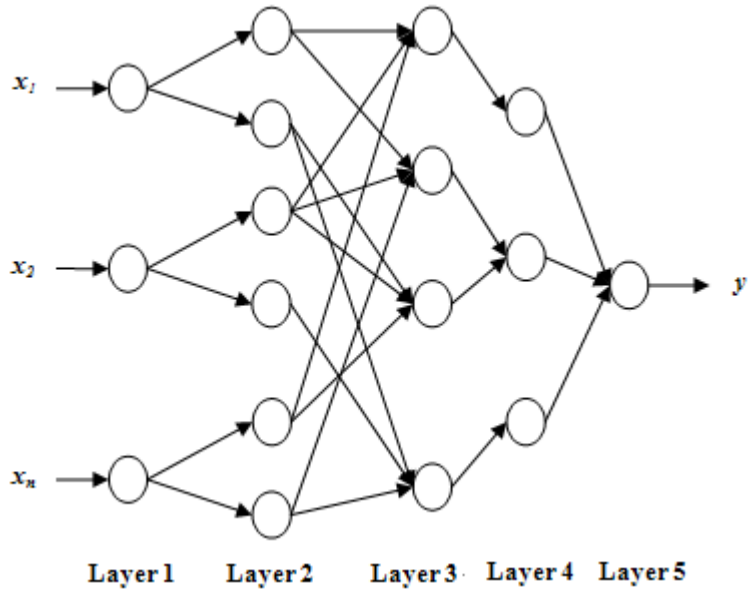

Figure 1. An ANFIS architecture for a two rule Sugeno system.

The ANFIS performs neural learning using fuzzy typed numbers. Given a set of input and output data, the ANFIS can constructs a fuzzy inference system with membership functions values adapted using a back propagation algorithm or in combination with a least square method. The adaptation function of the ANFIS provides the machine learning system with FNN characters. The basic model of the ANFIS is the Sugeno fuzzy model.

In this model, assuming $x=[x_1,x_2,\cdots x_n]^T$ are input fuzzy sets, and x_i are fuzzy language variables. Given the set of values of language variable as,

$$T(x_i)=\left\{A_i^1,A_i^2,\cdots,A_i^m,i=1,2,\cdots,n\right\} \tag{1}$$

where $A_i^j,(j=1,2,\cdots,m)$ is the jth value of language variable x_i, and $\mu_{A_i^j}$ is the corresponding membership function. Let y is the output fuzzy set, and the fuzzy if-then rules is formatted as,

$$if\,(x_1\ is\ A_1^{s_{1j}})\ and\ f(x_2\ is\ A_2^{s_{2j}})\ and\cdots and\ f(x_n\ is\ A_n^{s_{nj}}) \tag{2}$$

$$Then,\begin{cases} y_{1j}=p_{j0}^1+p_{j1}^1x_1+\cdots+p_{jn}^1x_n \\ \vdots \\ y_{rj}=p_{j0}^r+p_{j1}^rx_1+\cdots+p_{jn}^rx_n \end{cases} \tag{3}$$

$$y_k=\sum_{j=1}^{m}\overline{a}_j y_{kj} \tag{4}$$

where $a_j=\underset{i=1}{\overset{m}{\wedge}}\mu^s\lambda_i^j(x_i)$, and $\overline{a}_j=a_j\Big/\sum_{j=1}^{m}a_j$, $j=1,2,\cdots,m$. Figure 1 shows the Sugeno model and the corresponding ANFIS architecture with a five-layer artificial neural network. Denote that the output of the jth node of layer i are O_j^i. In Layer 1 of the ANFIS, the output of each node is:

$$O_{js_j}^1=\mu_j^{s_j}(x_j) \tag{5}$$

where $\mu_j^{s_j}$ are fuzzy membership functions. For nodes in Layer 2, the outputs of every node O_j^2 is fixed. This is where the t-norm is used to 'AND' the membership grades.

$$O_j^2=\min\left\{O_{1s_1}^1,O_{2s_2}^1,\cdots,O_{ns_n}^1\right\} \tag{6}$$

In Layer 3, the output of every node is normalized by a calculation as the following,

$$O_j^3 = \frac{O_j^2}{\sum_{j=1}^{m} O_j^2}, \quad j = 1,2,\cdots,m \tag{7}$$

While, Layer 4 is the de-fuzzy layer which adapts node values with,

$$O_k^4 = \sum_{j=1}^{m} y_{kj} O_j^3, \quad k = 1,2,\cdots,r \tag{8}$$

where the parameters p_{ji}^k in y_{kj} is the consequent parameters of the nodes. Finally, the fifth layer is to compute the output of all the input signals using the equation,

$$O_1^5 = \sum_{k=1}^{r} O_k^4 \tag{9}$$

Experiment Analysis and Result

We use the data collected from the sensors on GuangYing Bridge of Beijing-Chengde Highway. The data cover a time period between 00:00 am of 1st October, 2011 and 24:00 pm of 7th October, 2011. The raw data for speed, volume and occupancy are collected every 5min for the instrumented highway locations. The time plots of traffic volume, speed and occupancy are given in Figure 2(a), Figure 2(c) and Figure 2(e), respectively.

In the forecasting examples described below, the shifted values $X(t+L)$ are the predicted values based on sampled past values of a time series up to the point t, i.e. $X\{t-(D-1)d\}$, $X\{t-(D-2)d\}$ $,\cdots, X(t-d), X(t)$ .Therefore, the predictor to be implemented should map from D sample data points, sample at every d time units, as its input values to the predicted values as its output. The selection of D, d and L depend on the availability of the traffic time series and on its complexity. Here we always set $d = L$. First, we consider the case $d = L = 1$, $D = 2$. The forecasting results of traffic volume, speed and occupancy are given in Figure 2(b), Figure 2(d) and Figure 2(f), respectively.

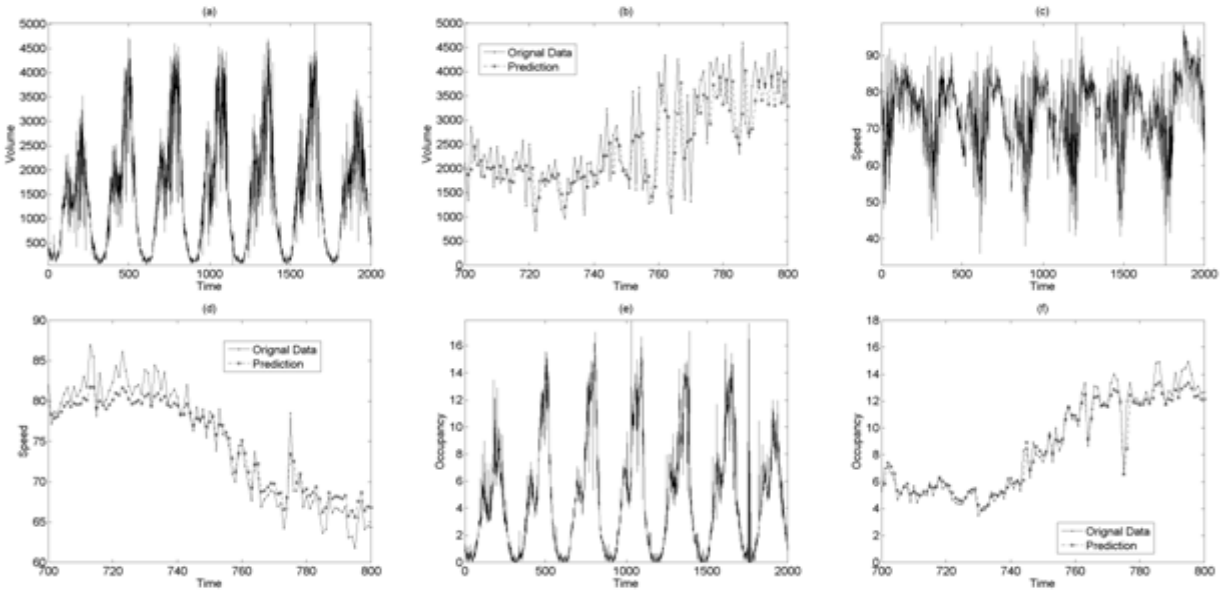

Figure 2. Time-series plot and prediction results of traffic volume, speed and occupancy

In order to compare the prediction results of different D, d and L, the prediction error is evaluated using the so-called nondimensional error index (NDEI) defined as,

$$NDEI = \frac{\sqrt{\frac{1}{N}\sum_{i=1}^{N}(T(i)-O(i))^2}}{\sigma(T)} \tag{10}$$

where :
$T(i)$ is the desired output, and $O(i)$ is the prediction, and $\sigma(T)$ is the standard deviation of the desired outpt. Table 1 show the NDEI of traffic volume prediction with different D, d and L. It can be seen from Table 1, it's the best choice of D, d and L, when we choose $d = L = 1$, $D = 2$.

Table 1. NDEI for traffic volume prediction with different D, d and L

D \ $d = L$	*1*	*2*	*3*	*4*	*5*	*6*
2	0.08	0.11	0.13	0.20	0.22	0.32
3	0.12	0.16	0.17	0.25	0.27	0.39
4	0.17	0.20	0.20	0.29	0.30	0.44

Conclusion

Decisions are almost made in scarce information. The collected data from traffic systems are usually limited and it's difficult to forecast. In this paper, the approach of fuzzy neuron network is presented to predict traffic time series with few data. The previous section clearly demonstrated the effectiveness of the proposed predictors. The so-called nondimensional error index (NDEI) is calculated with different D, d and L. Numerical simulation shows that the prediction is best when we choose $d = L = 1$, $D = 2$.

Keywords: Evaluation; Concrete Durability; Influence Factors; Grey Correlation Degree Method

Abstract. In this paper, under the environment of saline soil in the western region of Jilin Province, a series tests research on the durability of concrete has been made. The test results show that: there are a lot of factors that influence the durability of concrete, including the concrete itself internal factors and the external environmental factors. The correlation degrees between these influence factors and the durability of concrete are uncertain. In this paper, a grey correlation degree method has been used to analyze the correlation degrees between these influence factors and the dynamic elastic modulus loss rates of concrete, in order to determine the influence degree of each factor on the durability of concrete.

Introduction

In this paper, under the environment of saline soil in the western region of Jilin Province, a series tests research on the durability of concrete has been made [1-5]. The test results show that there are a lot of factors influencing the durability of concrete. Furthermore, the dynamic elastic modulus shows more sensitivity to concrete performance degradation than the mass. Therefore the dynamic elastic modulus is used as the evaluation index of the concrete durability. The correlation degrees between these factors and the concrete durability are uncertain. Grey correlation method has certain advantages in dealing with dynamic data uncertainties, so the correlation degrees between the influence factors and the loss rates of concrete dynamic elastic modulus are analyzed in this paper.

Correlated Coefficients and Correlation Degree Algorithm

Grey correlation degree method is to analyze the close extent of the reference sequence and several comparison sequences by using mathematical methods. If the geometry curves between them are much closer, it describes the greater of grey correlation degree, and vice versa [6]. In this paper, an improved grey correlation degree method has been selected to make algorithm[7,8]. The procedures are as follows:

(1) To determine the reference sequence and comparative sequence [9, 10]:

$$\text{Reference Sequence:}\quad X_0 = \{X_0(k), k = 1, 2, \cdots, m\} \tag{1}$$

$$\text{Comparative sequence:}\quad X_i = \{X_i(k), k = 1, 2, \cdots, m; i = 1, 2, \cdots, n\} \tag{2}$$

In which, m represents the number of comparison related to the reference factors, n represents the number of dynamic observations in the same period.

According to the indicator of concrete durability, the reference sequence can be determined. In this paper, the reference sequence of X_0 is constituted by the dynamic elastic modulus loss rate. 7 influencing factors (freeze-thaw cycle, dry-wet cycle, freeze-thaw and dry-wet cycle, long-term soaking, multi-salt solution concentration, air content, and amount of fly ash) are used as compared sequence X_i. According to the test results, a total of 7 influencing parameters, and 893 sets of data have been gotten, ie. n=7, m=893.

(2) The first regressive to reference sequence X_0 and compared sequence X_i, namely

$$y_i(t+1) = X_i(t+1) - X_i(t) \tag{3}$$

$$y_0(t+1) = X_0(t+1) - X_0(t) \quad (i = 1,2,3,4; t = 1,2,\cdots,n-1) \tag{4}$$

To make regressive treatment to y_0 and y_i, then to seek the relative change rate k in reference sequence X_0 and comparative sequence X_i, namely:

$$k_i(t+1) = y_i(t+1) / \overline{X_i} \quad , \quad \overline{X_i} = \sum_{t=1}^{n} x_i(t) / n \tag{5}$$

$$k_0(t+1) = y_0(t+1) / \overline{X_0} \quad , \quad \overline{X_0} = \sum_{t=1}^{n} x_0(t) / n \tag{6}$$

(3) To calculate the correlation coefficient *ri(k)* and correlation degree *ri* between reference sequence X_0 and comparative sequence X_i, namely:

$$r_i(t) = sign / (1 + | 1 + || k_i(t) | - | k_0(t) ||) \tag{7}$$

$$r_i = \sum_{t=2}^{n} r_i(t) / (n-1) \tag{8}$$

In the formula, $sign = \begin{cases} 1 & y_i(t) \times y_0(t) \geq 0 \\ -1 & y_i(t) \times y_0(t) < 0 \end{cases}$

According to the positive or negative correlation degree of *Ri*, the correlation property between compared sequence X_0 and reference sequence X_i can be determined. When *ri* is in positive, it indicates that X_0 and X_i are positively correlated, ie. The increase (decrease) of X_0 can directly lead to the increase (decrease) of X_i; When *ri* is in negative, X_0 and X_i are negatively correlated, ie, the increase (decrease) of X_0 will directly lead to the decrease (increase) of X_i.

Analysis Process of Influencing Factors and Grey Correlation Degree to Concrete Durability

Table 1 shows the data of loss rate of concrete dynamic elastic modulus in the series of previous tests, which is looked as the reference sequence X_0; 7 influencing factors are looked as compared sequence X_i, in which n=7, m=893. The calculation process to correlation degree is shown in Fig. 1. After the algorithm, a correlation degreeγ_i (X_0, X_i) is gotten between 7 influencing factors and the dynamic elastic modulus loss rate.

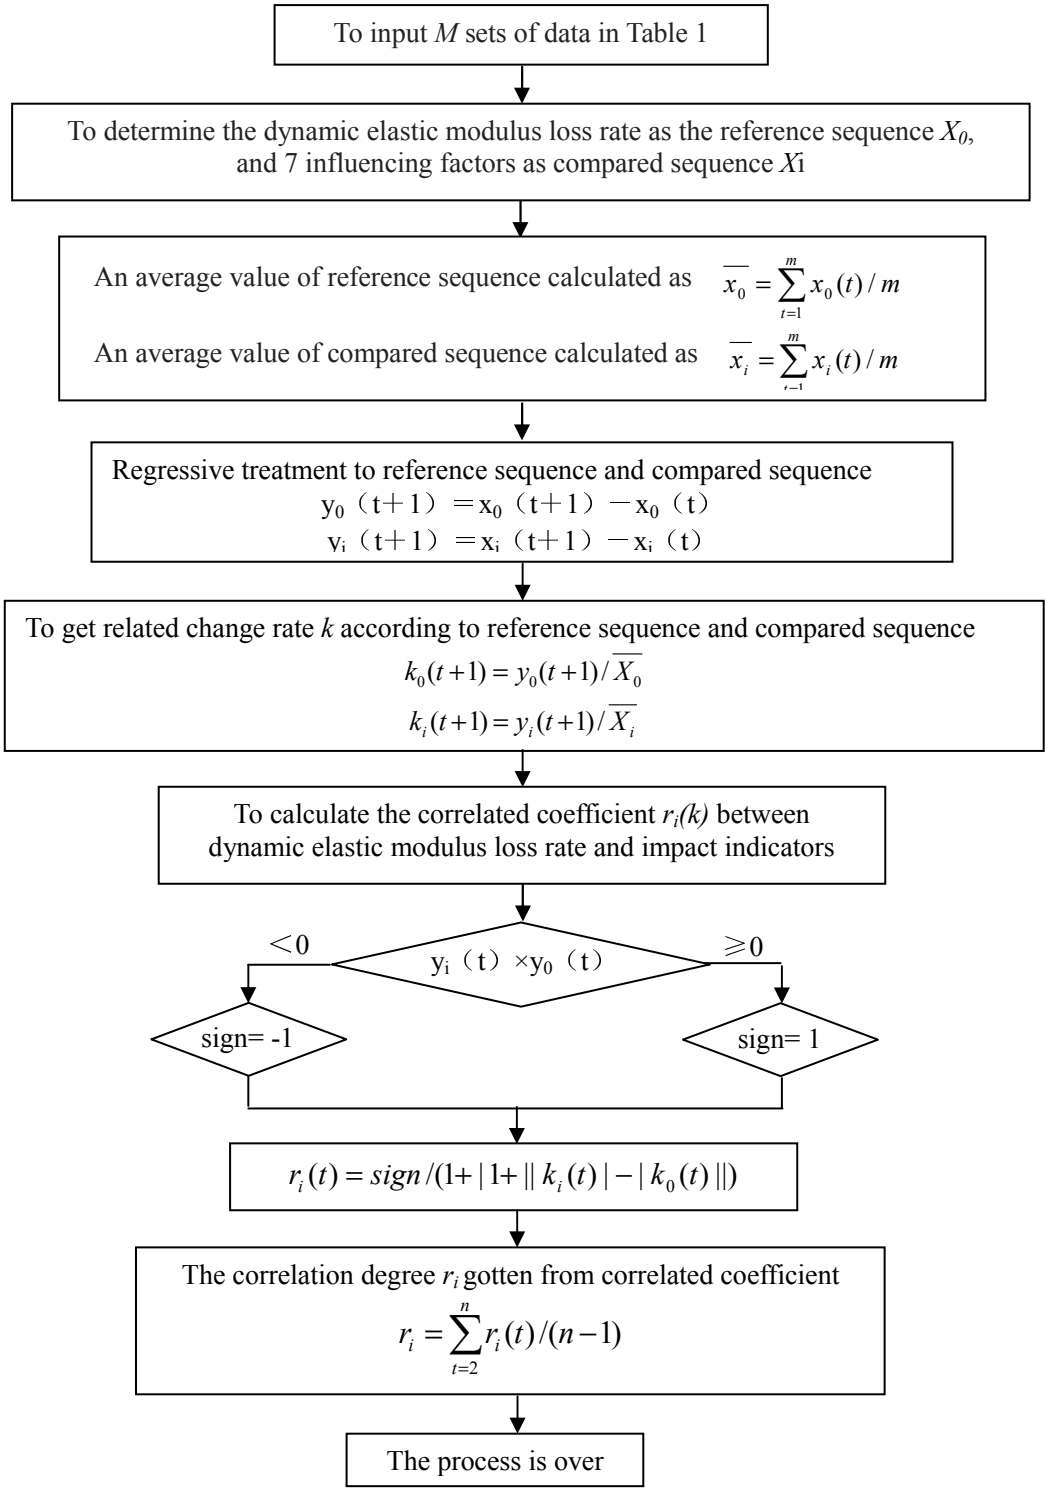

Fig. 1 Correlation Degree Algorithm Procedure Chart

The Correlation Degree between Influence Factors and Dynamic Elastic Modulus Loss Rate

The algorithm results of correlation degree between influence factors and dynamic elastic modulus loss rate of concrete are shown in Table 2. The results show: the correlation degrees are in descending order as: freeze-thaw and dry-wet cycle> dry-wet cycle> freeze-thaw cycle> air content> multi-salt solution concentration> amount of fly ash> soaking time.

Table 2 Correlation Degree between Influence Factors and Dynamic Elastic Modulus Loss Rate

Influence factors	Freeze-thaw cycles	Dry-wet cycles	Freeze-thaw and dry-wet cycles	Long-term soaking	Multi-salt solution concentration	Air content	Amount of fly ash
Correlation degree γ	0.801	0.808	0.813	0.702	0.717	-0.755	0.694

As can be seen from Table 2, environmental factors have a most prominent correlation to the decay of concrete dynamic elastic modulus loss rate, and the correlation degree between them in descending order as: freeze-thaw and dry-wet cycle> dry-wet cycle> freeze-thaw cycle> soaking time. It describes that multiple environmental factors simultaneously action will impact attenuation properties of concrete more serious than a single environmental factor. Therefore, the concrete project serving in dry-wet environment or seasonal frozen area will have a poor durability. The concrete project existing in harmful salt environment will have a relatively slower decay of the properties of concrete because salt erosion of concrete is a long time process.

The correlation degree between multi-salt solution concentration and dynamic elastic modulus loss rate is high up to 0.717, indicating the higher levels of harmful salts, the greater damage to the concrete performance, and different salts will have different effective results to concrete. Under the saline soil environment in western region of Jilin province, HCO_3^- has a greater impact on concrete dynamic elastic modulus; even though the content of SO_4^{2-} is lower than Cl^-, the impact to concrete dynamic elastic modulus will be greater than Cl^-; whereas the impact of Cl^- on concrete mass loss rate is greater than SO_4^{2-}. This also explains that the erosion of Cl^- to concrete mainly causes the concrete peeling off, the erosion of SO_4^{2-} to concrete mainly causes the decay of concrete dynamic elastic modulus, and the damage due to reduced strength. The erosion and damage of harmful salts to concrete should arouse enough attention.

In addition, the air content and dynamic elastic modulus loss rate of concrete are in negatively correlated (γ = -0.755), and with a larger absolute value, indicating that the greater air content, the slower decay to dynamic elastic modulus, and the better durability of concrete. Therefore, in order to improve the durability of concrete, mixing the right amount of air-entraining agent in concrete is an effective and simple method. Under the same circumstance, the correlation degree between fly ash content and dynamic elastic modulus loss rate is 0.694, and with a weaker impact on the durability of concrete. It will be depended by the concrete serving environment on whether mixing fly ash.

Conclusion

In summary, the good or bad concrete durability is related to environmental factors and the material properties of the concrete. The material properties are the intrinsic factors to determine the durability of concrete, and the environmental conditions are the external factors that affect the durability of concrete. In order to improve the durability of concrete, the various kinds of factors in serving environment of concrete project should be fully considered, such as the selection of appropriate materials, and a reasonable design on concrete mix proportion.

Keywords: Camshift algorithm; Object tracking; Multi-feature fusion; Texture feature; histogram

Abstract. Camshift is an efficient single-feature algorithm based on color-kernel for simple object tracking. However, it's easy to be interfered by sudden illumination variation or the similar color object in the background. Experiments show that the improved algorithm can track object accurately in dealing with sudden illumination variation and the similar color object in the background, and can meet the requirements of the actual task of object tracking.

0. Introduction

MeanShift and CamShift algorithm is the typical representatives of the mean shift algorithm in moving object tracking algorithm[1]. In these two methods, color histogram is used to indicate the target model, through iteration target centroid to track object. Look from the calculation, MeanShift algorithm[2] is slightly complicated, and the size of tracking template is fixed, cannot adapt to the object size scaling, therefore CamShift algorithm applies more widely, which is able to provide a template adaptive adjustment.

In view of the poor tracking quality of the characteristic of single color CamShift tracking algorithm under the condition of illumination change obviously or similar background interference , edge and texture information were fused with color information in this article, established the characteristics of target template, formed the CamShift tracking algorithm based on multiple features adaptive fusion[3], And further improvements have been proposed on these basis through modify feature-histogram and set a reasonable search region. Experimental results show that the improved CamShift algorithm can effectively deal with the interference.

1. Multi-feature adaptive fusion Camshift algorithm

Considering the problem that the tracking effect of the traditional single color features Camshift tracking algorithm is poor when illumination changes significantly, this article uses the color Hue component, Sobel edge gradient, and local three value mode (LTP) texture[4] to establish multi-feature model, and realize the adaptive fusion according to some fusion rules, thereby enhance algorithm robustness to illumination change.

LTP operator computation formula is as follows. In the formula, nc is the center pixel value (x, y), ni is the pixel value of p pixels which are interval distributed on the circle, its center is (x, y) and radius is R.

$$LTP_{P,R}(x,y)=\sum_{i=0}^{P-1}s(n_i-n_c)3^i$$

$$s(x)=\begin{cases}1, & x\geq T\\ 0 & -T<x<T\\ -1, & x\leq -T\end{cases} \tag{1}$$

On the basis of the above, this article also optimized feature weights on the attenuation mechanism, in order to ensure that when a certain features have been unable to achieve tracking its weights can be small enough. Set S_1, S_2, S_3 represent the value ofα,β,γrespectively, d_1, d_2, d_3, represent the similarity value under the color, edge, texture feature, which is obtained by the

formula (1) (the range is [0, 1], and the higher the value, the greater the similarity), T_1, T_2 and T_3 represent thresholds for judging α,β,γrespectively, e-ax is a index function (a=10), the feature weights can be adjusted according to the formula:

$$S_i = \begin{cases} S_i & d_i \le T_i \\ S_i e^{-a(d_i - T_i)} & d_i > T_i \end{cases} \quad (i = 1,2,3) \tag{2}$$

From the above, for some feature, when the similarity value *di* between search window histogram and background window histogram is less than the threshold value T_i, the feature weights S_i remain unchanged; On the other hand, the weights of S_i will be carried out in accordance with the exponential attenuation $e^{-a(d_i - T_i)}$. T_i changes with the change of feature and scene (T_i is 0.5 in this article).

2. The further improvement of the algorithm

Multi-feature adaptive fusion Camshift algorithm is improved on the robustness than traditional Camshift tracking algorithm, but there are still some defects. For example, in the scenarios with similar background (especially the three feature models are close to the background), the algorithm still cannot achieve stability tracking. For this problem, this paper made some further improvements based on the multi-feature adaptive fusion Camshift tracking algorithm. The improvement strategy is as follows.

3. Analysis of experimental results

In experiment 1, the paper respectively use the traditional Camshift tracking algorithm based on single color features and the Camshift tracking algorithm based on multiple features adaptive fusion for target tracking. In using video clips, target to orange and with a certain texture features of ellipse, the target has moved from the darker area to a light region.

Figure 1 shows the target tracking results of traditional Camshift algorithm, can be seen from the diagram, as the change of light intensity, The tracking window of Camshift algorithm which is sensitive to illumination change based on color feature expands unceasingly, the tracking effect is poor.

Figure 2 shows the target tracking results of the Hue component of color features and LBP texture feature fusion Camshift tracking algorithm, which is proposed in the literature [5], from the diagram, the ability of strain illumination change for the improved algorithm is still poor.

Figure 3 shows the target tracking results of Camshift tracking adaptive fusion algorithm based on the Hue component of color features, Sobel edge and LTP texture feature which are proposed in this paper, the algorithm has good tracking performance and strong robustness.

The changes of each feature weights (the initial weights of edge, color, texture feature are 1/3) in figure3 were recorded in Table 1. Can be seen from the table, on the 18th frame and 26th frame, the sum of the weight of three features is not 1, the reason is that feature weights of the attenuation according to formula (2).In the process of tracking, while the influence of the edge feature under illumination changes is not big, but because of its ability to rotate is poorer, and the target is rotating, so the ratio of edge feature in the table has been is not high, and the greater the degree of target rotational deformation, the smaller the edge feature weights. Also can be seen from table 1, in the 26th frames, weight of color feature is only 0.180342, the reason for this is that near the 26 frame, the target is in a transition from the dark area to a lighter area. Due to the color feature is sensitive to illumination change, the search window and background window in this area are hard to distinguish, so the weight of color feature is reduced. In addition, because the texture feature affected by illumination change and rotation is not big, so its weight has been higher.

Table 1 Analysis of feature weight changes

4. Conclusion

Camshift tracking algorithm based on single feature is often failure for the tracking because of the limitations of the features. In view of this, this article fused the multiple features, constitute a multi-feature fusion Camshift tracking algorithm, make full use of the complementarity between different features, to better adapt to the scene changes, and enhance the robustness of target tracking.

Keywords: Plasma; RF wave heating; numerical simulation

Abstract. Wave heating is an important way to implement the controlled fusion. The propagation and absorbability of wave in the plasma are described by the two-fluid equations and Maxwell's equations. A numerical algorithm based on the FDTD method and the MacCormack scheme is designed. The numerical simulation based on parallel computing is carried out to verify the validity of the algorithm and simulation.

Introduction

A promising and possible way to develop and use fusion energy is magnetic confinement fusion [1]. The tokamak is a device using a large toroidal background magnetic field to confine the fusion plasma in the shape of a torus. In order to reach the high enough temperature and satisfy the fusion ignition condition, both of ohmic heating and auxiliary heating play an important role in the tokamak reactor. The toroidal current induced by the transformer in a tokamak reactor produces ohmic heating. The fact shows that the temperature provided by ohmic heating is limited; therefore, the other auxiliary heating methods are required to increase the fusion plasma temperature, such as the radio frequency (RF) wave heating [2]. If the launching frequency is given, the RF wave will resonate with one of eigenfrequencies of the electrons or ions in the plasma. The wave-particles resonance is the basic mechanism by which the plasma could absorb energy from incident RF wave. Thus, it is very important to research the propagation and absorbability of the RF wave in the plasma.

The propagation and absorbability of the RF wave are described by the two-fluid equations and Maxwell's equations. A numerical algorithm suitable for simulation is put forward to solve the equations. As a first step it is important to examine the validity of the algorithm and simulation. In this paper, only topics related to the algorithm design and numerical simulation of linear wave propagation in the cold plasma will be discussed. The simulation of nonlinear process in the hot plasma deserves to be discussed more comprehensively in the future. So this will not be proposed in this paper. The outline of this paper is as follows. In Section 2 a brief introduction of the simulation model is presented. The design method of the algorithm is described in Section 3. The numerical simulation results are presented in Section 4 and Section 5 is a short summary.

Simulation Model

In tokamak, the plasma is constrained in the shape of a torus. In the cross section which is perpendicular to the toroidal direction, the equilibrium density of plasma increases to a maximum N_0 in the core of the torus, and then decreases to a minimum value in the other edge. The direction of the background static magnetic field $\boldsymbol{B}_0$ is along the toroidal direction. The density of the background magnetic field increases monotonically. The value of the background static magnetic field in the center of plasma is B_0. In our model, the toroidal direction is assumed as z direction and the density gradient of the plasma is x direction. For simplicity, we assume that all the electric and magnetic fields exhibit no spatial variation in y direction. Thus, the simulation model has been converted into two-dimensional space [3].

Since the electrons and ions in the plasma are treated as fluids, the motion of electrons and ions are described by the two-fluid equations [4]. The temporal and spatial evolution of the electromagnetic field is described by Maxwell's equations. Consider the plasma with equilibrium density gradient in x direction $N_{e0}= N_0(x)$ and $N_{i0}= N_0(x)$, perturbed electron fluid and ion fluid densities N_{e1} and N_{i1}, unperturbed electric field $\boldsymbol{E}_0=0$, unperturbed electron fluid and ion fluid velocities $\boldsymbol{u}_{e0}=0$ and $\boldsymbol{u}_{i0}=0$, perturbed electron fluid and ion fluid velocities $\boldsymbol{u}_{e1}$ and $\boldsymbol{u}_{i1}$, perturbed electric field $\boldsymbol{E}$, and perturbed magnetic field $\boldsymbol{H}$. The basic equations are:

$$\frac{\partial N_e}{\partial t} + N_e \nabla \cdot \boldsymbol{u}_e + \boldsymbol{u}_e \cdot \nabla N_e = 0 \tag{1}$$

$$\frac{\partial N_i}{\partial t} + N_i \nabla \cdot \boldsymbol{u}_i + \boldsymbol{u}_i \cdot \nabla N_i = 0 \tag{2}$$

$$\frac{\partial \boldsymbol{u}_e}{\partial t} + \boldsymbol{u}_e \cdot \nabla \boldsymbol{u}_e + \frac{e}{m_e}\left[\boldsymbol{E} + \boldsymbol{u}_e \times (\boldsymbol{B}_0 + \mu_0 \boldsymbol{H})\right] = 0 \tag{3}$$

$$\frac{\partial \boldsymbol{u}_i}{\partial t} + \boldsymbol{u}_i \cdot \nabla \boldsymbol{u}_i - \frac{e}{m_i}\left[\boldsymbol{E} + \boldsymbol{u}_i \times (\boldsymbol{B}_0 + \mu_0 \boldsymbol{H})\right] = 0 \tag{4}$$

$$\nabla \times \boldsymbol{E} = -\mu_0 \frac{\partial \boldsymbol{H}}{\partial t} \tag{5}$$

$$\nabla \times \boldsymbol{H} = \varepsilon_0 \frac{\partial \boldsymbol{E}}{\partial t} + e(N_i \boldsymbol{u}_i - N_e \boldsymbol{u}_e) \tag{6}$$

where e and $m_e(m_i)$ are the charge and the mass of an electron(ion), respectively. $N_e(N_i)$ and $\boldsymbol{u}_e(\boldsymbol{u}_i)$ both contain unperturbed quantity and perturbed quantity. Here, the nonlinear terms are included into the equations just to ensure the integrity of equations. They are deferred for future studies.

Algorithm Design

It's obvious that partial differential terms are contained in the basic equations. In order to deal with these terms, the MacCormack scheme is used to solve the two-fluid equations. The Finite Difference Time Domain (FDTD) method is applied to solve Maxwell's equations. In addition, due to the large computational space all the simulations are based on parallel program with Message Passing Interface (MPI).

The FDTD method was first proposed by K.S. Yee in 1966 [5]. The partial differential equations are transformed to finite-difference equation from by the spatial and temporal discretization of the electromagnetic field vector. Having assumed the perturbed quantities with no spatial variation in y direction, we consider TE wave as the incident wave. The perturbed electric field $\boldsymbol{E}$ has two polarization components E_x and E_z. The perturbed magnetic field $\boldsymbol{H}$ has only one component H_y [6]. The two-dimensional Maxwell's equations are:

$$\frac{\partial H_y}{\partial t} = \frac{1}{\mu_0}\left(\frac{\partial E_z}{\partial x} - \frac{\partial E_x}{\partial z}\right) \tag{7}$$

$$\frac{\partial E_x}{\partial t} = -\frac{1}{\varepsilon_0}\frac{\partial H_y}{\partial z} + \frac{e}{\varepsilon_0}(N_e u_{ex} - N_i u_{ix}) \tag{8}$$

$$\frac{\partial E_z}{\partial t} = \frac{1}{\varepsilon_0}\frac{\partial H_y}{\partial x} + \frac{e}{\varepsilon_0}(N_e u_{ez} - N_i u_{iz}) \tag{9}$$

The numerical solution of E_x is selected to explain the process of discretization as an example. The difference form of the equation is:

$$E_x\Big|_{i+1,j}^{n+1} = E_x\Big|_{i+1,j}^{n} - \frac{\Delta t}{\varepsilon_0}\frac{H_y\Big|_{i,j+1}^{n} - H_y\Big|_{i,j}^{n}}{\Delta z} + \frac{e\Delta t}{\varepsilon_0}\frac{N_e\Big|_{i+1,j}^{n} + N_e\Big|_{i,j}^{n}}{2}\frac{u_{ex}\Big|_{i+1,j}^{n} + u_{ex}\Big|_{i,j}^{n} + u_{ex}\Big|_{i+1,j}^{n-1} + u_{ex}\Big|_{i+1,j}^{n-1}}{4} - \frac{e\Delta t}{\varepsilon_0}\frac{N_i\Big|_{i+1,j}^{n} + N_i\Big|_{i,j}^{n}}{2}\frac{u_{ix}\Big|_{i+1,j}^{n} + u_{ix}\Big|_{i,j}^{n} + u_{ix}\Big|_{i+1,j}^{n-1} + u_{ix}\Big|_{i+1,j}^{n-1}}{4} \tag{10}$$

Similarly, the numerical solutions of E_z and H_y can be obtained. In Eq. 10, subscripts i and j refer to the spatial position of a certain point in the x-z two-dimensional plane, respectively. The superscripts n and n+1 refer to a certain moment and the next moment, respectively. This result looks a little complex since semi-implicit form is applied to deal with the difference of $N_e(N_i)$, $u_{ex}(u_{ix})$ and $u_{ez}(u_{iz})$ [7]. The method can effectively improve the numerical stability.

To the two-fluid equations, numerical results had tested that MacCormack scheme was suitable for this model. It is based on explicit difference scheme and has second-order accuracy in time and space. In the fluid model, the density of electron fluid can be calculated by the following form:

$$N_e\Big|_{i,j}^{n+1} = N_e\Big|_{i,j}^{n} + (\frac{\partial N_e}{\partial t})_{av}\Delta t \tag{11}$$

where $(\partial N_e/\partial t)_{av}$ is a representative mean value of $\partial N_e/\partial t$ between times t and t+Δt. In MacCormack scheme, this average time derivative $(\partial N_e/\partial t)_{av}$ is obtained from a predictor-corrector philosophy.

Predictor step: In Eq. 1, the spatial derivative term is approximated by a forward difference. Thus, the predicted value of density is obtained as follows.

$$\frac{\partial N_e}{\partial t}\Big|_{i,j}^{n} = -(N_e\Big|_{i,j}^{n}\frac{u_{ex}\Big|_{i+1,j}^{n} - u_{ex}\Big|_{i,j}^{n}}{\Delta x} + u_{ex}\Big|_{i,j}^{n}\frac{N_e\Big|_{i+1,j}^{n} - N_e\Big|_{i,j}^{n}}{\Delta x} + N_e\Big|_{i,j}^{n}\frac{u_{ez}\Big|_{i,j+1}^{n} - u_{ez}\Big|_{i,j}^{n}}{\Delta z} + u_{ez}\Big|_{i,j}^{n}\frac{N_e\Big|_{i,j+1}^{n} - N_e\Big|_{i,j}^{n}}{\Delta z}) \tag{12}$$

$$\overline{N_e}\Big|_{i,j}^{n} = N_e\Big|_{i,j}^{n} + \frac{\partial N_e}{\partial t}\Big|_{i,j}^{n}\Delta t \tag{13}$$

Corrector step: The spatial derivative term is approximated by a backward difference. We first obtain the predicted value of the time derivative at t+Δt. Thus, the final corrected value is obtained.

$$\frac{\partial \overline{N_e}}{\partial t}\Big|_{i,j}^{n+1} = -(\overline{N_e}\Big|_{i,j}^{n+1}\frac{\overline{u_{ex}}\Big|_{i,j}^{n+1} - \overline{u_{ex}}\Big|_{i-1,j}^{n+1}}{\Delta x} + \overline{u_{ex}}\Big|_{i,j}^{n+1}\frac{\overline{N_e}\Big|_{i,j}^{n+1} - \overline{N_e}\Big|_{i-1,j}^{n+1}}{\Delta x} + \overline{N_e}\Big|_{i,j}^{n+1}\frac{\overline{u_{ez}}\Big|_{i,j}^{n+1} - \overline{u_{ez}}\Big|_{i,j-1}^{n+1}}{\Delta z} + \overline{u_{ez}}\Big|_{i,j}^{n+1}\frac{\overline{N_e}\Big|_{i,j}^{n+1} - \overline{N_e}\Big|_{i,j-1}^{n+1}}{\Delta z}) \tag{14}$$

$$N_e\Big|_{i,j}^{n+1} = N_e\Big|_{i,j}^{n} + (\frac{\partial N_e}{\partial t})_{av}\Delta t = N_e\Big|_{i,j}^{n} + \frac{1}{2}(\frac{\partial N_e}{\partial t}\Big|_{i,j}^{n} + \overline{\frac{\partial N_e}{\partial t}}\Big|_{i,j}^{n+1})\Delta t \tag{15}$$

Other quantities N_i, $\boldsymbol{u}_e$ and $\boldsymbol{u}_i$ in the two-fluid equations are obtained by the same method.

In computations, the whole simulation region is divided into several sub-regions in x direction. Every sub-region is assigned to certain cluster resource and storage resource. The data of the two adjacent sub-regions are exchanged by non-block communication functions, *MPI_Isend* and *MPI_Irecv*. The parallel simulation program is submitted to the server cluster with Linux OS and carried out on the MPICH2 environment.

Results and Discussion

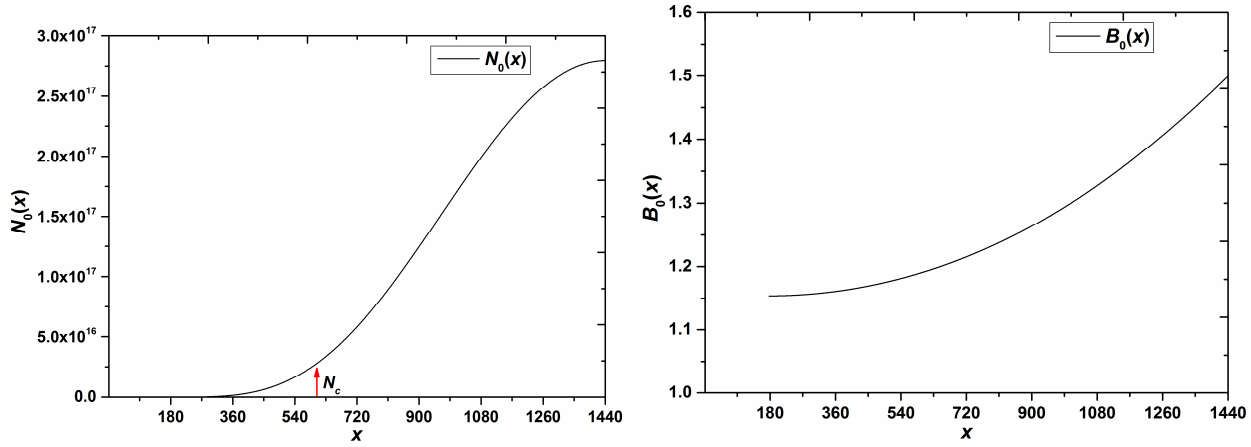
Based on the algorithm above, we investigate the coupling effects between the lower hybrid wave (LHW) and the magnetized plasma in order to examine the validity of the algorithm and simulation. The parameters used in the numerical simulation are shown as Table 1. The linear theory of wave propagation has indicated that the coupling and propagation are strongly affected by the parallel wavenumber k_z, the same direction as $\boldsymbol{B}_0$, and k_0, k_0=ω/c, where ω is the frequency of the incident wave and c is the velocity of light [8]. If the parallel wavenumber k_z is less than k_0, the

wave couldn't propagate into the plasma from the vacuum. If the parallel wavenumber k_z is more than k_0 , the wave will evanesce in the outer layer of the edge plasma, where the density N_e is below the critical density N_c that given by $\omega_{pe}=\omega$, and propagate in the internal layer, where the density N_e is above the critical density N_c [9].

Table 1. Parameters used in the numerical simulation

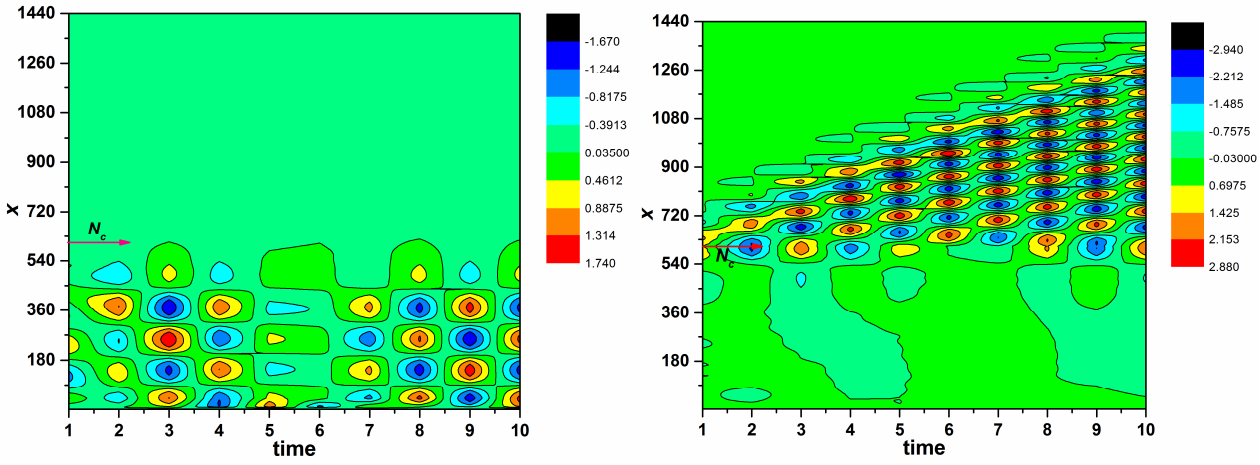
Grid spacing Δx Δz	$0.02\pi c/\omega$
Time step Δt	$0.002\pi/\omega$
Number of grids in x-axis L_x	1440
Number of grids in z-axis L_z	120
Number of time steps	50000
Value of density N_0	2.79×10^{17}
Value of magnetic field B_0	1.5T

In x direction, the grids from 1 to 180 are in the vacuum and the grids from 181 to1440 are in the plasma. The position of the critical density N_c is at x=600. The background magnetic field only exits in plasma. In the simulation model, the distribution curves of the equilibrium density $N_0(x)$ and the background magnetic field $B_0(x)$ are shown as Fig. 1.



(a) distribution of $N_0(x)$ (b) distribution of $B_0(x)$

Fig.1 The distributions of $N_0(x)$ and $B_0(x)$



(a) k_z=0.8k_0 (b) k_z=1.2k_0

Fig.2 The numerical solution of H_y

Two different situations for k_z=0.8k_0 and k_z=1.2k_0 are simulated, respectively. Here, the spatial and temporal evolution of H_y from numerical solution is shown in Fig. 2.

Obviously, the wave can't propagate in the region, x>600Δx, where the density $N_0(x)$ is above the critical density N_c, for the first situation k_z=0.8k_0. When it comes to the other situation, k_z=1.2k_0, the value of H_y is zero in the region, x<600Δx and the waveform appears in the region, x>600Δx. These results mean that the incident wave can propagate into the internal layer of plasma which also shows that our simulation results are in accordance with the linear theory.

Summary

Based on the two-fluid equations and Maxwell's equations, the numerical algorithm is designed to study the propagation of the RF wave in the plasma. In present study, we treat a simple case that the background plasma to be a cold plasma medium and ignore the nonlinear effects. The numerical algorithm contains the FDTD method and the MacCormack scheme. On the basis of the simulation results, we can clarify that the numerical algorithm and numerical simulation are useful and convincing. For future studies, we will treat the plasma as a hot plasma and investigate the wave-particles interaction with nonlinear effects.

Keywords: Electromagnetic Forming; Workpiece Deformation; Finite Element Method

Abstract. Electromagnetic forming is a kind of processing technology that use lorentz force to make rapid prototyping of metal workpiece, which can significantly improve the metal forming performance,and it is expected to become an emerging technology that alternative to traditional machining to process light alloy materials. Based on the understanding the basic structure of the electromagnetic coupling on the basis of physical process of electromagnetic forming, this article adopt ANSYS sequential coupling method to simulate the electromagnetic coupling process of electromagnetic structure, and analysis of tube electromagnetic forming and plate of workpiece in the process of free bulging deformation behavior. The solenoid coil tubing have an axis of symmetry due to bulging, and it's electromagnetism load and constraint has symmetry, so its formability is uniform in hoop direction. When the plank free bulge, the distribution of the electromagnetic force caused by the flat spiral coil is not uniform,and the artifacts accelerate fastest in the part of the radius of coil 1/2, but the center area of the workpiece's forming height is highest.

Introduction

Electromagnetic forming is a kind of processing technology that use lorentz force to make rapid prototyping of metal workpiece, and the forming process rank millisecond, forming speed is generally more than 300 m/s [1][2], the schematic diagram as shown in Fig. 1. Through the capacitor power discharge to drive coil, there produce powerful pulse current in the drive coil, at the same time eddy current is producted in the metal artifacts. Electromagnetic force between excitation current and the induced current drive metal workpiece to accelerate and lead to plastic deformation. Electromagnetic pulse shaping is the use of magnetic force to sheet metal forming, which has the following characteristics:

In the pulsed electromagnetic force, the work obtain a large kinetic and energy to achieve the forming acceleration at the moment. The intensity of magnetic pulse can accurately control, easy to realize mechanization and automation. Electromagnetic forming load force to plate via the medium of magnetic field. There are no mechanical contact and forming surface have a high quality.

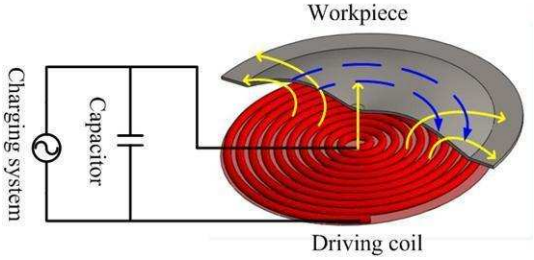

Fig. 1. Electromagnetci forming process.

AL-Hassani studied and analyzed the electromagnetic force distribution of different shapes coil on the sheet metal [3]; Takatsu studied the free bulging process of electromagnetic plank taking the flat spiral coil for example , and the simulation and experimental results are basically identical [4]. Scholars studied and simulated the electromagnetic tube bulging process and so on, with the method of electromagnetic and structural decoupling, namely, the loosely coupling method [5] [6].

Fenton and Daehn analyzed the Planar-Magnetic free bulging process by using the algorithm of 2 d arbitrary Lagrangian,and the simulation results matched with the experiment very well [7]. However, loosely coupling method did not consider the influence between the structure and the magnetic field , so the model is only applicable to the simulative electromagnetic forming process of small deformation workpiece.

Based on the understanding of basic electromagnetic structure coupling process of electromagnetic forming,this article adopts a sequence coupling method to simulate the electromagnetic coupling process of electromagnetic structure, and analyzes the deformation behavior of workpiece in the process of tube electromagnetic forming and plate workpiece's free bulging.

Basic principle of electromagnetic forming

Field forming process of pulse high magnetic field is a complicated physical field coupling issue, involving many other disciplines such as the electromagnetic field, structure field, temperature field and material science. In view of the main problems,the forming process can be considered as a coupling physical process of electromagnetic structure. the electromagnetic process of workpiece's inside can be calculated according to Faraday's law of electromagnetic induction:

$$\nabla \times E_{\varphi} = -\frac{\partial B_z}{\partial t} \quad (1)$$

The electromagnetic force of workpiece is:

$$F_z = J_{\varphi} \times B_r \quad (2)$$

In the forming process of pulse magnetic field, the workpiece speeds up and becomes distored under the action of pulse electromagnetic force . Bz and Br in equation (1) and (2) stand for the magnetic flux density inside the workpiece.Apart from its being associated with time, its value is related to the workpiece deformation caused by the displacement changes. At the same time, the magnetic flux density distribution also varies with the shape changing. Magnetic flux density and electromagnetic force, along with the change of displacement and shape workpiece are the workpiece structure field effect of electromagnetic field.

Sequential coupling method

Because of the development of computer technology and finite element software,finite element simulation study of pulsed magnetic field has become one of the main physical processes shaping the electromagnetic coupling structure.Sequential coupling method has achieved the analysis of electromagnetic coupling structure. The specific flow chart shown in Figure 1:Build geometric models;Clear structural loads and boundary setting, Set electromagnetic model unit type, load, borders, etc. Written electromagnetic physical environment;Clear electromagnetic load and boundary setting,Forming structural unit type field and boundary conditions.Written to structure physical environment; settings the simulation time and time step, the preparation of the electromagnetic coupling cycle program sequence structure:Read out electromagnetic physics model, solving electromagnetic model; read out structure physical model, loaded electromagnetic force load, solving the structure of the model;Updated according to the results of the workpiece and nearby structures air grid; determine whether the step is the last step, if not, continue to the next magnetic field and deformation analysis, and if so, stop the cycle, end coupling analysis.Generally, high pulsed magnetic field formed the discharge process as microseconds, milliseconds forming process; After the discharge, the movement and deformation of the workpiece can do a simple structural analysis. Therefore, in order pulsed magnetic field coupling loop ends after forming, usually set up a new simulation time and time step, the process used to analyze the deformation of the workpiece under the action of inertial force.

Analysis of deformation behavior

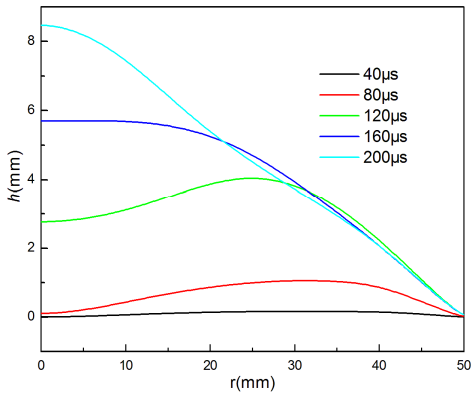

Fig. 2. Workpiece deformation behavior.

With flat spiral coil plate free bulging, circle constraints outside the workpiece must be fixed; Due to uneven distribution of flat spiral coil of electromagnetic force, the artifacts accelerate fastest in the part of the radius of coil 1/2(as shown in fig. 2); When the 1/2 of workpiece was accelerated to high speed, the central portion of the workpiece is drived to accelerated, eventually the center area formed the highest height due to the minimum binding. Figure 5 showed the free forming process of electromagnetic plate,which clearly reflects the free bulging's deformation process.

Conclusion

Electromagnetic forming process is a complicated physical field coupling problem, which involves the electromagnetic field, structure field, temperature field and material science, and other disciplines. In view of the main problems, pulse magnetic field forming can be considered as an physical process of electromagnetic structure's coupling.That adopt the electromagnetic structure coupling finite element method to analyze the electromagnetic forming process, can effectively response deformation behavior of work piece under different loading conditions, and also can provide powerful theory basis for parameters optimization design of electromagnetic forming.

Keywords: Radial Basis Function; Neural Network; Extended Kalman Filter; Learning Algorithm

Abstract. To improve the learning capability of Radial Basis Function (RBF) neural network, a RBF neural network algorithm based on Extended Kalman Filter (EKF) is proposed. First the basic idea of EKF algorithm and RBF neural network are introduced, and then EKF is used to optimize the parameters combination of RBF neural network to obtain the better model. The experiment proves its feasibility.

Introduction

RBF neural network has many advantages, and has been widely used such as image recognition, speech recognition, nonlinear system identification and so on. According to the characteristics of RBF neural network, a variety of RBF neural network algorithms have been proposed, but these algorithms has the shortcoming such as poor explanation, requirement of high quality data, theory depth and so on.

Based on this, a extended Kalman filter algorithm for RBF neural network training is proposed to optimize the parameters of the network from sample data. The experiments show its validity.

Extended Kalman filter algorithm

Kalman filter is a highly efficient recursive filter (autoregressive filter) that can estimate the state of dynamic system. be measured from a series of measurement without incompletely containing noise. This filter method was named by its inventor R. E. Kalman. However, the simply Kalman Filter need be applied in system following Gauss distribution, later scholars had made many improvements on it, one of which is Extended Kalman Filter (EKF) [1] that can be applied in the nonlinear dynamic system.

Filter theory initially proposed by Kalman is only suitable for linear systems, Bucy, Sunahara et al proposed and studied EKF, and it be further applied in the field of nonlinear filtering theory. The basic idea of EKF is that first the nonlinear system is linearized, and then Kalman flter is executed, so EKF is a suboptimal filter. In addition, the proposition and application of various second-order EKF methods further improve the estimation performance of Kalman filter for the nonlinear system. The second -order filter method considers the quadratic term of Taylor series expansion, thus it can reduce the estimation error caused by the linearization, but greatly increases the amount of computation, so campared to first-order EKF[2], it was not used widely in practice.

When the state equation and measurement equations are nonlinear, EKF usually is adopted. EKF conduct the first-order linearization truncation for Taylor expansions of nonlinear function, ignoring the rest of the high order item, thus the nonlinear problem is transformed into the linear problem, Kalman filter algorithm of can be applied in the nonlinear system, which solves the nonlinear problem.

For a nonlinear discrete systems

$$x_t = \Phi_{t,t-1} x_{t-1} + \Gamma_{t-1} w_{t-1} \tag{1}$$

$$z_t = H_t x_t + v_t \tag{2}$$

where t is the present moment, x_t is the system state vector, z_t is the observation vector, $\Phi_{t,t-1}$ is the state transition matrix, H_t is the observation matrix. Process noise w_t and measurement noise v_t is the series with unrelated zero mean white noise, its statistical characteristics is as follows:

$$E[w_t] = 0;\ E[w_t w_j^T] = Q_t \delta_{tj} \tag{3}$$

$$E[v_t] = 0;\ E[v_t v_j^T] = R_t \delta_{tj} \tag{4}$$

$$E[w_t v_j^T] = 0 \tag{5}$$

where $\delta_{tj} = \begin{cases} 1 & t = j \\ 0 & t \neq j \end{cases}$.

Suppose that the initial state of statistical characteristics is

$$E[x_0] = \mu_0;\quad E[(x_0 - \mu_0)(x_0 - \mu_0)^T] = P_0 \tag{6}$$

and x_0 is completely irrelevant to w_t, v_t, namely

$$Cov(x_0, w_t) = 0;\quad Cov(x_0, v_t) = 0 \tag{7}$$

The filtering process of the system is as follows:

$$\hat{x}_{t|t-1} = \Phi_{k|k-1} \hat{x}_{t-1} \tag{8}$$

$$\hat{x}_t = \hat{x}_{t|t-1} + K_t (z_t - H_t \hat{x}_{t|t-1}) \tag{9}$$

$$K_t = P_t H_t^T R_t^{-1} \tag{10}$$

$$P_{t|t-1} = \Phi_{t,t-1} P_{t-1} \Phi_{t,t-1}^T + \Gamma_{t-1} Q_{t-1} \Gamma_{t-1}^T \tag{11}$$

$$P_t = (I - K_t H_t) P_{t|t-1} \tag{12}$$

RBF neural network

Neural network has a strong ability of nonlinear fitting, and can execute the mapping for arbitrarily complex nonlinear relation with simple learning rules and easy computer realization. It has very strong robustness, memory capacity, nonlinear mapping ability and strong self-learning ability, so it has great application foreground[3].

RBF neural network is a feed-forward neural network with excellent performance. RBF network can approximate any nonlinear function through arbitrary precision, and has the ability of global approximation, solving the problem of local optimum BP neural network radically, and its topology structure is compact, its structure parameters can realize the separation learning with fast convergence speed[4]. The advantages of RBF neural network mainly include:

① It has a unique optimal approximation properties without local minimum.

② RBF neural network has strong mapping function for input and output, and it has be proved that, in feed-forward neural network, RBF neural network is the best network completing the mapping function.

③ The relationship between connection weights and output of network is linear.

④ It has a good classification ability.

⑤ The learning process has a rapid convergence speed.

In fact, RBF neural network generally has only one hidden layer with RBF activation function. For Fig.1 shows the structure of RBF neural network, the expression of RBF neural network is as follows:

$$z=\sum_{i=1}^{n}\omega_i f(\|x-C_i\|/\delta_i) \tag{13}$$

or if considering threshold value we have

$$z=\sum_{i=1}^{n}\omega_i f(\|x-C_i\|/\delta_i)+d \tag{14}$$

where ω_i is the connection weight of output layer, C_i is the center of radial basis function, $f(\cdot)$ is the RBF function, $x\in R^n$ is the input of neural network, δ_i is the sensitive domain of RBF, d is the threshold value of output layer, $\|\bullet\|$ is the distance operator, n is the number of hidden neurons.

Suppose that the training samples $S_m=\{X_i,Z_i\}$, $i=1,2,\cdots,m$, then the training process of RBF neural network is to hunt for $\Theta=\{C_i,\delta_i,\omega_i\}$ to acheive the minimization of following function

$$\min e_{RBF}(S_m,F_n(X,\Theta))=\frac{1}{m}\sum_{i=1}^{m}|Z_i-F_n(X,\Theta)|^2 \tag{15}$$

$$F_n(X,\Theta)=\sum_{i=1}^{n}\omega_i f(\|x-C_i\|/\delta_i) \tag{16}$$

Because the output layer of RBF neural network is the linear neurons, so as long as C_i and δ_i are determined, the parameters of output layer can be constructed by least square method. In learning algorithm of RBF neural network, the main task is to search the optimal vector $\Theta=\{c_i,\sigma_i,w_i\}$.

Learning process of RBF neural network based on extended Kalman filter

The state space model is a dynamic model in time domain in which the connotative time is regarded as the argument. Application of state space model in the analysis of time series are increasing rapidly. The state space model that is more commonly applicated is the canonical correlation method proposed by Akaike and further evolved by Mehra. The new method of state space model that can estimate the vector value proposed by Aoki et al can get the state space model with so-called internal balance, if only the corresponding element in the system matrix can be removed, any low order approximation model can be obtained without re-estimation, and as long as the original model is stable, low order approximation model obtained is also stable.

For RBF neural network shown in Fig.1, its network learning is optimal estimation for the network parameters Θ (including c_i,σ_i,w_i) so as to search the optimal network parameters. Therefore, Θ is taken as the state variables of the network system, the output as the measurement equation of the network, the state space model of RBF neural network can be expressed as

$$\Theta_{t+1}=\Theta_t+\eta_t \tag{17}$$

$$z_t=f(X_t,\Theta_t)+\mu_t \tag{18}$$

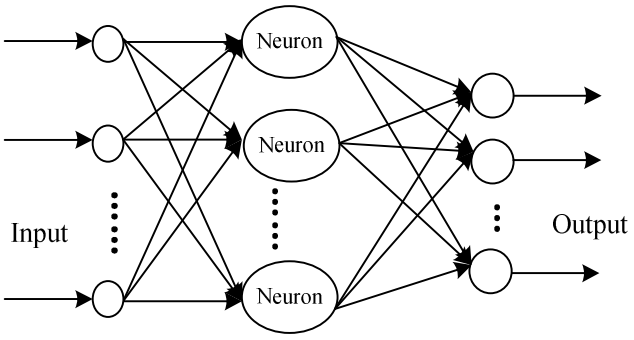

Fig.1 Topology Structure of RBF neural network

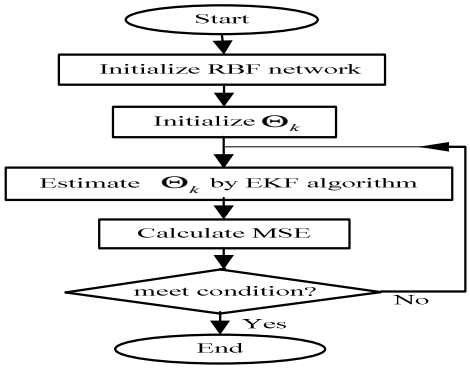

Fig.2 Flow of EKF-RBFNN

where X_t is the input of the network, z_t is the output of the network, $f(X_t, \Theta_t)$ is the nonlinear function parameterized. η_t is the process noise and in paper is taken as Gauss white noise with mean 0 and variance Q_t, η_t is the measurement noise and in paper is taken as Gauss white noise with mean 0 and variance R_t, noise.

Through EKF training RBF neural network, we can use EKF algorithm to obtain the optimal parameter vector $\Theta = \{c_i, \sigma_i, w_i\}$. The training flow of RBF neural network using EKF algorithm is shown in Fig. 2, where Mean Square Error (MSE) is taken as the error indicators of network training.

Simulation example

The simulation object is a function with multi-peak and dramatic changes as follows

$$y_i = \frac{\sin(9x_i)}{(x_i - 0.16)^2 + 0.1} \tag{19}$$

Suppose that the training set is 100 points following the uniform distribution in $[0,6]$, namely $\{(x_1, y_1), \cdots, (x_{100}, y_{100})\} \in R^1 \times R^1$. The training input is $x_1, x_2, \cdots, x_{100}$; the training output is $y_1, y_2, \cdots, y_{100}$. The input of the test set is 100 points that are randomly generated in $[0,6]$, the test output is the corresponding function values according to the formula (19).

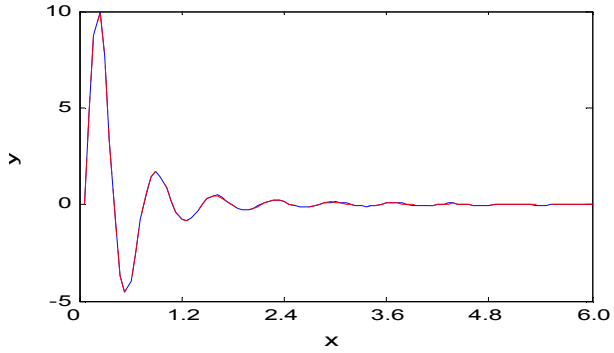

Fig.3 Approximation effect of function

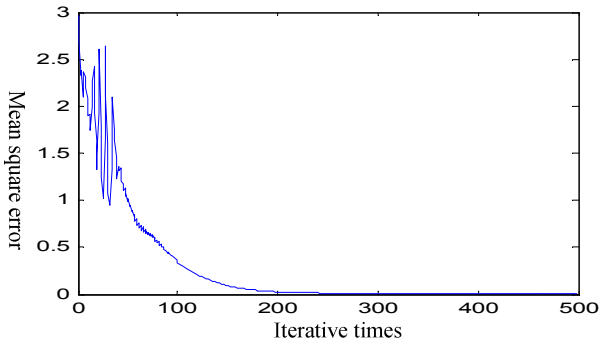

Fig.4 Training convergence curve

The experiment result as shown in Fig.3 and Fig.4 indicates that, the proposed learning algorithm of RBF neural network based on EKF has a good approximation ability with rapid convergence rate.

Conclusions

A learning algorithm of RBF neural network using EKF is proposed. In the algorithm, the traditional EKF algorithm is used to estimate the optimal parameters of RBF neural network for the network training . The simulation indicate that this learning algorithm can achieve a good modeling ability.

Keywords: NN; CAZAC; Application; Interpolation

Abstract. In order to adapt the spectrum property of Zadoff-Chu sequence to the requirement of HF channel sounding transmitter-receiver, the Formula Direct Interpolation Algorithm (FDIA) is put forward by which the amplitude frequency characteristic of Zadoff-Chu sequence can be enhanced. Then the comparison of spectra of the sequences respectively interpolated by FDIA and commonly used interpolation algorithm is conducted, which affirms the superiority of FDIA. Finally, an effective method of achieving best decimation of the sequence interpolated by FDIA is provided. All these lay primary theory foundation for the application of Zadoff-Chu sequence to HF channel sounding.

Introduction

CAZAC sequence with a length of N^2 (N is an integer) which was used in the Zadoff-Abourezk patent of a synchronizing system was first proposed by Frank in 1950s. The CAZAC sequence proposed by Frank was described afresh by Frank and Zadoff in. Based on the work of Frank and Zadoff, D[1]. Chu proposed a sort of CAZAC sequence without restriction on its length, that is, Zadoff-Chu sequence. And he proved that certain linear phase shift of the form $\exp(j2\pi qk/N)$, when introduced into the sequence will not affect its correlation property, where q , k and N are integers, and k is relatively prime to L[2].

The spectrum of Zadoff-Chu sequence is flat in the full bandwidth, even though its periodic autocorrelation property is perfect, which indicates that the sequence cannot be transmitted directly by channel sounding transmitter because its energy is decentralized. Therefore, an interpolation algorithm is needed, by which the spectrum of Zadoff-Chu sequence can be compressed for the transmission in HF channel. Consequently, the paper proposes an interpolation algorithm which is suitable for Zadoff-Chu sequence, that is, the FDIA. Then the comparisons of the spectra, the real parts and the imaginary parts of the sequences respectively interpolated by FDIA and commonly used interpolation algorithm are carried out. The decimation method of the sequence interpolated by FDIA is investigated and an efficient method by which the optimal decimation position can be found is provided. The method makes use of the periodic auto-correlation property of Zadoff-Chu sequence. The simulation results show that the periodic auto-correlation property of Zadoff-Chu sequence is perfect[3]. The spectra of the sequence respectively interpolated by FDIA and commonly used interpolation algorithm have the same main-lobe width, but the spectrum of the sequence interpolated by FDIA has a faster roll-off and almost no big side-lobes. Besides, the optimal decimation position of the sequence interpolated by FDIA can be easily found out by the method provided[4].

The paper is organized as follows: Section II describes the periodic auto-correlation property of Zadoff-Chu sequence. In Section III, the FDIA is proposed. The comparisons of the spectra, the real parts and the imaginary parts of the sequences respectively interpolated by FDIA and commonly used interpolation algorithm are carried out in this section, too. Section IV provides the decimation method of the sequence interpolated by FDIA.

Correlation Property of ZADOFF-CHU Sequence

Fig.1 shows the PACF of Zadoff-Chu sequence with k=1 and L=1024. The PACF of m sequence with period of 1023 is also depicted in Fig.1 to clearly illustrate the perfect periodic autocorrelation property of Zadoff-Chu sequence. In addition, theoretical calculations show that the peak to side-lobe ratio of the PACF of Zadoff-Chu sequence ups to 280dB, and the peak to sidelobe ratio of the PACF of m sequence is only 60dB.

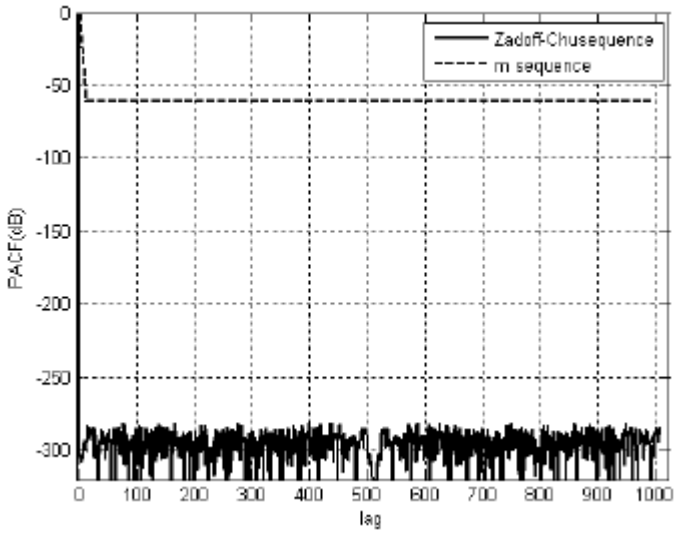

Fig.1 Normalized PACFs of Zadoff-Chu Sequence and m Sequence

Comparison of FDIA and the commonly used interpolation algorithm

Fig.2 shows the real parts and the imaginary parts of the original Zadoff-Chu sequence with L=32 and k=1 and of the sequences respectively 8 times interpolated by FDIA and commonly used interpolation algorithm. The real line represents the sequence interpolated by FDIA and the broken line represents the sequence interpolated by the commonly used interpolation algorithm.

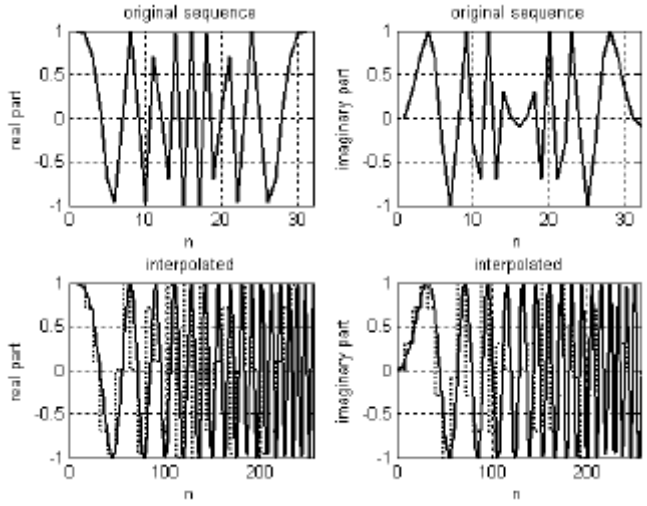

Fig.2 Waves of sequences respectively interpolated by FDIA (real line) and commonly used interpolation algorithm (broken line)

Motion Control Section

Motion control section can be divided into the control part and actuator, which is a classic servo closed loop position control, Motion control section diagram shown in Fig.3. Movement control card can receive PC control instruction, and the axes interface to be controlled send pulses to relevant servo controller to control motor rotation angle, and then ball-screw will convert rotation

angle to horizontal displacement, so as to carry the infrared supply horizontal or vertical movement. The control part mainly includes movement control card, servo controller and so on, motor control command is sent through the PC software to regular the movement control card to produce the corresponding output pulse. The whole movement process need two axes motor control respectively, it is adequate for us to use the movement control card supported four axes, and available for circular interpolation, continuous linear interpolation, so the card can meet the equipment requirements. Actuator is a key part of the whole system, which is designed three-rail plane, including two horizontal rails and one vertical rail, ball-screw inside, which can drive the slider with infrared light supply to move in the whole plane. There at the edge of rail separately installs limit switch and origin switch to determine the origin and the maximum boundary. The parts of actuators in detail designed as Fig.4 shows.

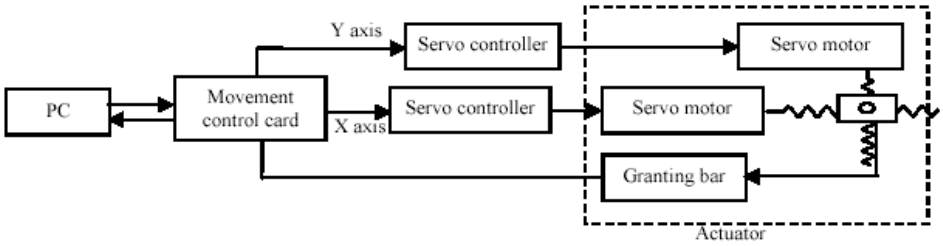

Fig.3 Motion control section

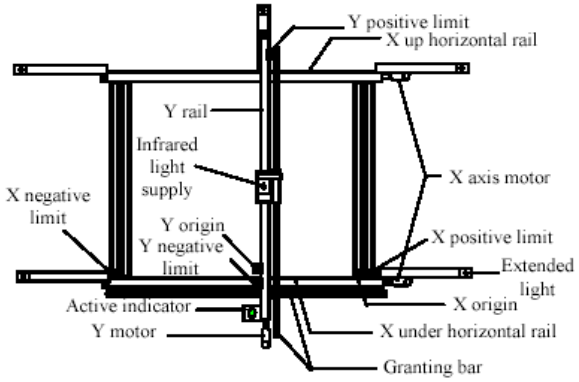

Fig.4 Part of actuator

Neural Network Augmented Model Inversion Architecture

This section details the architecture of the NN augmented model inversion as applied to the tiltrotor aircraft. Fig.5 contains a diagram of the architecture used for implementation of ACAH control in the pitch channel. The command filter serves both to limit the input rate, and as a model for desired response. This allows for straightforward implementation of ADS-33 handling qualities specifications. The presented architecture provides for excellent results in the longitudinal application, as is shown in following sections. Identical construction applies to the lateral channels.

The results in the lateral channels show similar performance.

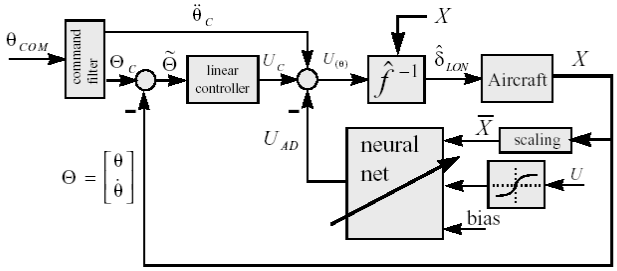

Fig.5 Adaptive NN augmented model inversion architecture in the longitudinal channel configured for ACAH

Conclusion

In HF channel oblique sounding, the selection or design of sounding sequences is a key technique. The paper investigates the periodic autocorrelation property of Zadoff-Chu sequence based on the introduction of the definition and properties of CAZAC sequences. Aiming at resolving the problem that the spectrum of Zadoff-Chu sequence is not band-limited which makes it be not suitable for transmission in HF channel, the FDIA is proposed in the paper by which the amplitude frequency characteristic of Zadoff-Chu sequence can be enhanced. The comparisons of the spectra, the real parts and the imaginary parts of the sequences respectively interpolated by FDIA and commonly used interpolation algorithm are carried out. At the same time, an effective method of achieving optimal decimation of the Zadoff-Chu sequence interpolated by FDIA is provided. The simulation results show that the periodic auto-correlation property of Zadoff-Chu sequence is perfect. The spectra of the sequence respectively interpolated by FDIA and commonly used interpolation algorithm have the same main-lobe width, but the spectrum of the sequence interpolated by FDIA has a faster roll-off and almost no big side-lobes, which means that it has a higher energy using ratio when transmission in narrow band HF channel. Hereby, this paper lays primary theory foundation for the application of Zadoff-Chu sequence to HF channel oblique sounding.

In the control process, it is convenient to process all necessary parameter setting and adjustment, and in the control process of the whole system the photovoltaic simulator shows superior performance and achieves the expected effect.

Comparison on turnovers of agricultural products futures based on Hilbert-Huang transform

Qingbin Han[1, a],Haili Shi[2,b]

[1]University of Science and Technology Liaoning, Anshan, China

[2] Northeastern University, Shenyang, China

[a] hanneu@163.com, [b]421666182@qq.com

Keywords: Turnover amounts, Non-stationary signals, Hilbert-Huang transform, Empirical mode decomposition.

Abstract. In order to distinguish the different patterns and evolving trends on turnovers of agricultural products futures between Zhengzhou Commodity Exchange (Z-CE) and Dalian Commodity Exchange (D-CE), a novel time-frequency analysis approach, i.e. Hilbert-Huang transform (HHT), is investigated in this paper. Firstly, Hilbert-Huang transform is briefly introduced. Secondly, two different non-stationary signals of turnover of agricultural products futures from 2009 to 2013 coming from Z-CE and D-CE are described in Empirical Mode Decomposition (EMD). With these results, the two signals are distinctly different from each other. It is proved that the technique of HHT is effective for the purpose of distinction of turnover of agricultural products futures in commodity exchanges.

Introduction

Turnover of agricultural products futures of Zhengzhou Commodity Exchange (Z-CE) and Dalian Commodity Exchange (D-CE) includes so much information that it can be used to diagnose, treat or predict economic trends. The data turnover of agricultural products futures has one or more of the following problems, (a) the total data span is too short, (b) the data is non-stationary and (c) the data represents nonlinear process.

The time series of turnover of agricultural products futures is mainly regarded that, for the signal itself, there are stationary or non-stationary properties, while the linear or nonlinear properties should refer to its original system [1]. In economic community, most of the systems are regarded to be nonlinear; moreover, their signals are often non-stationary.

Historically, Fourier spectral analysis has provided a general method for examining the global energy-frequency distributions, but has some inherent restrictions, for example, the system must be linear and the data must be strictly periodic or stationary. So how to identify or at least to distinguish the non-stationary properties of the signals is of major concerned. In recent years, some time-frequency processing methods for nonlinear and non-stationary signals have been proposed, such as wavelet analysis, Wigner-Ville distribution, etc [2-5].

Recently, a new method based on Hilbert-Huang transform (HHT) for analyzing non-stationary signals has been proposed [6], in which the expansion bases are adaptive for signals from nonlinear and non-stationary processes. Based on this method, any complicated signals can be decomposed into a finite and often small number of 'Intrinsic Mode Functions' (IMFs) that admit well-behaved Hilbert transforms. And with the Hilbert transform, the IMFs yield instantaneous frequencies as functions of time that give sharp identifications of embedded structures. The final presentation of the results is an energy-frequency-time distribution, designated as the Hilbert spectrum.Compared to the Fourier-based linear and stationary spectral analysis and other time-frequency analysis methods, HHT is now considered a great breakthrough and used in non-stationary analyses and processing fields [7-9].

In this paper, we choose turnover of agricultural products futures between Zhengzhou commodity exchange and Dalian commodity exchange to analysis. From their time domain waveforms and their power spectrum densities, they are not easily to be distinguished. In using HHT, we obtain effective distinctions between them. The results demonstrate that HHT is effective

to identify the features of non-stationary signals of turnover of agricultural products futures between Zhengzhou commodity exchange and Dalian commodity exchange.

Basic algorithm procedure of HHT

HHT involves two aspects: empirical mode decomposition (EMD) and Hilbert spectral analysis (HAS) [6]. Firstly, a time-adaptive decomposing operation named EMD is applied to a signal, in which the signal are decomposed into a set of complete and almost orthogonal components named Intrinsic Mode Functions (IMFs). Secondly, with Hilbert transforming of those IMFs, a full energy-frequency-time distribution of the signal is obtained [10- 11].

The IMFs, which are regarded as both the amplitude modulation and the frequency modulation, satisfy the following requirements: 1) the number of extremes and the number of zero crossings in the IMF must either be equal or different at most by one; and 2) at any point the mean value of the envelopes defined by the local maxima and local minima must be zero. The process to find the IMFs of a signal $x(t)$ comprises the following steps:

1) Find the positions and amplitudes of all local maxima and minia in the input signal $x(t)$. Then create an upper envelope by cubic spline interpolation of the local maxima, and a lower envelope by cubic spline interpolation of the local minima.

2) Calculate the mean of the upper and lower envelopes; this is defined as $m_1(t)$.

3) Subtract the envelope mean from the original input signal,

$$h_1(t) = x(t) - m_1(t). \tag{1}$$

4) Check whether $h_1(t)$ meets the requirements to be an IMF. If the sifting result $h_1(t)$ is an IMF, stop the process. Otherwise, treat $h_1(t)$ as the new signal data and iterate on $h_1(t)$ through the previous step 1) ~ 4). That is, to set

$$h_{11}(t) = h_1(t) - m_{11}(t). \tag{2}$$

Repeat this sifting procedure k times until $h_{1k}(t)$ is an IMF. This is designated as the first IMF, shown below

$$c_1(t) = h_{1k}(t). \tag{3}$$

5) Subtract $c_1(t)$ from the input signal and define the remainder, $r_1(t)$, which is the first residue as following,

$$r_1(t) = x(t) - c_1(t). \tag{4}$$

6) Since the residue $r_1(t)$ still contains information related to longer period components, it is treated as a new data stream and the above-described sifting process is repeated until the last IMF. This procedure can be repeated n times to generate n residues, $r_n(t)$, and result in

$$r_2(t) = r_1(t) - c_2(t), \ldots, r_n(t) = r_{n-1}(t) - c_n(t). \tag{5}$$

The sifting process stops when either of two criteria are met: 1) the component $c_n(t)$, or the residue $r_n(t)$, becomes so small as to be considered inconsequential; or 2) the residue, $r_n(t)$, becomes a monotonic function from which an IMF can not be extracted. For example, the stopping condition for an IMF is

$$\sum_t \frac{[h_{k-1}(t) - h_k(t)]^2}{h_{k-1}^2(t)} < S. \tag{6}$$

where $h_k(t)$ is the sifting result in the kth iteration, and S is typically set between 0.2 and 0.3. Besides, in order to achieve the last IMF, a simple way can be used. The last IMF could be obtained when the cubic spline fitting stops due to the number of local maxima or minima of the residue is less than 2.

Finally, we obtain

$$x(t) = \sum_{j=1}^{n} c_j(t) + r_n(t). \tag{7}$$

In other words, the original signal can now be represented as the sum of a set of IMFs plus a residue.

Now apply Hilbert transform to all IMFs,

$$H\left[c_j(t)\right]=\frac{1}{\pi}\int_{-\infty}^{\infty}\frac{c_j(\tau)}{t-\tau}\mathrm{d}\tau . \tag{8}$$

After the Hilbert transform, $H\left[c_j(t)\right]$ and $c_j(t)$ form a complex signal. So, the envelope of every IMF $c_j(t)$,, is given by

$$a_j(t)=\sqrt{c_j^2(t)+(H[c_j(t)])^2} . \tag{9}$$

The phase functions are

$$\Phi_j(t)=\arctan\frac{H[c_j(t)]}{c_j(t)} . \tag{10}$$

And the instantaneous frequencies are obtained as

$$\omega_j(t)=\frac{\mathrm{d}\Phi_j(t)}{\mathrm{d}t} . \tag{11}$$

Having obtained the components of IMFs, we will have no difficulty to apply Hilbert transform to each component of them. With the Hilbert transform of each IMF component, we can express the signal in the following form,

$$X(t)=\sum_{j=1}^{n}a_j(t)\exp(i\int\omega_j(t)dt) . \tag{12}$$

Equation (12) also enables us to represent the amplitude and the instantaneous frequency as functions of time in a three-dimensional space, in which the amplitude can be contoured on the frequency-time plane. This frequency-time distribution of the amplitude is designated as the Hilbert amplitude spectrum, i.e. $H(\omega,t)$. With the Hilbert spectrum defined, we can also define the marginal spectrum, i.e. $h(\omega)$, as following

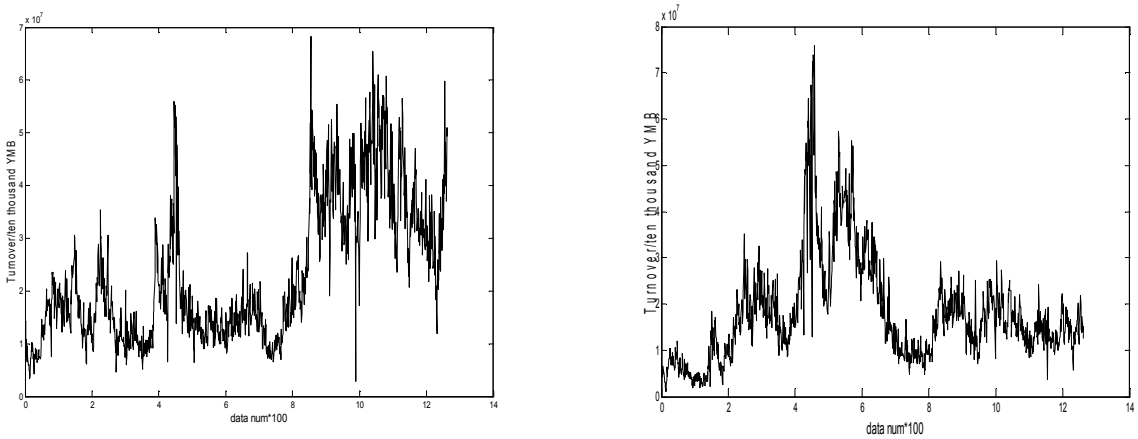
$$h(\omega)=\int_0^T H(\omega,t)dt . \tag{13}$$

The marginal spectrum offers a measurement of the total amplitude (or energy) contribution.

Results

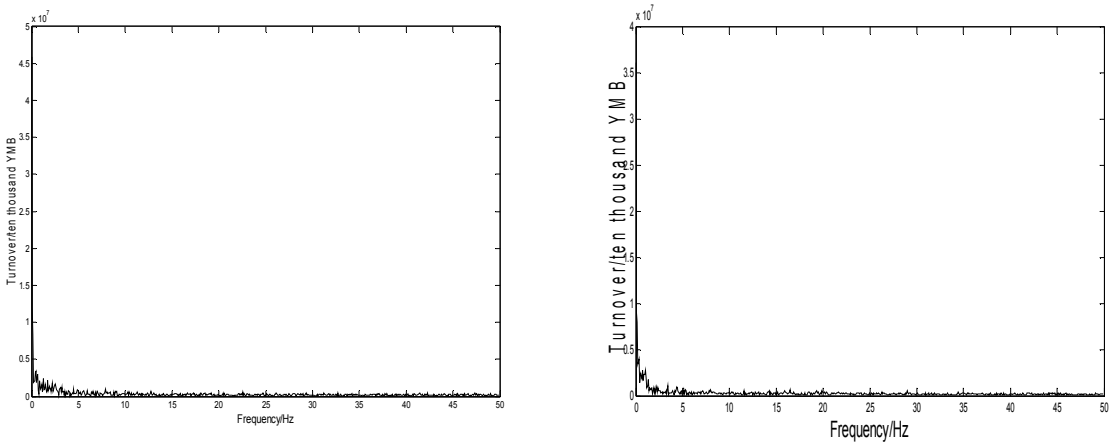
We choose two time series of turnover of agricultural products futures between Zhengzhou commodity exchange and Dalian commodity exchange to be analyzed. These two time series are recorder as turnover of every day agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange from the beginning of 2009 to the end of 2013.

There are two different non-stationary signals are shown in Fig 1, and there amplitude spectrum densities are shown in Fig 2 correspondingly. From Fig 1, the difference is obviously. But it is not easy to identify one from each other.



(a) (b)

Fig.1 Original signals of turnover of agricultural products futures
(a)Zhengzhou commodity exchange (b)Dalian commodity exchange



(a) (b)

Fig.2 Frequency spectra of original signals of turnover of agricultural products futures
(a) Zhengzhou commodity exchange (b)Dalian commodity exchange

Now apply HHT for the two signals. The calculated IMFs and instantaneous frequency (IFs) of turnover of agricultural products futures of Zhengzhou commodity exchange and turnover of agricultural products futures of Dalian commodity exchange are shown in Fig 3 and Fig 4.

From Fig.3 (a) and (b), we can see that there are both seven IMF components from signal of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange. So we can say that the signal of the two turnovers contain same frequency components which embody there same complexity in quantities way. The first IMF of turnover of agricultural products futures of Zhengzhou commodity exchange, c1, appears as amplitude modulation, is also completely different from that in turnover of agricultural products futures of Dalian commodity exchange. The second and third orders of the IMF of turnover of agricultural products futures of Zhengzhou commodity exchange, i.e. c2 and c3, appear frequency modulations, while turnover of agricultural products futures of Dalian commodity exchange is not. Correspondingly, IF of every IMF of the two time series are shown in Fig.4 (a) and (b), which are physically meaningful, and the differences between two time series are clearer.

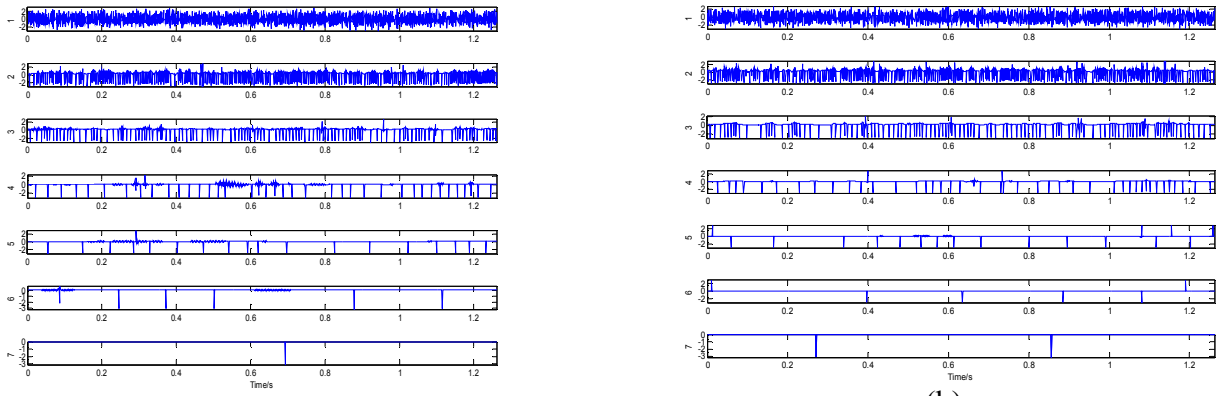
(a) Zhengzhou commodity exchange (b)Dalian commodity exchange



(a) (b)

Fig. 4 Instantaneous frequencies of turnover of agricultural products futures
(a) Zhengzhou commodity exchange (b)Dalian commodity exchange

Furthermore, their frequency spectra of Instantaneous frequencies are also obtained according to the results of IMFs. They are shown in Fig. 5. For the frequency spectra of Instantaneous frequencies of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian exchange, they offer the measurements of the total amplitude contributions from each frequency value. From Fig 5, we can find the values and their tendency of the total amplitude contributions of turnover of agricultural products futures are remarkable different of Zhengzhou commodity exchange and Dalian exchange. From the two frequency spectra of Instantaneous frequencies of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian exchange, we can distinguish the differences between them as well.

Conclusions

Turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange as two different non-stationary signals are used as examples to be described and distinguished in the time-frequency analyses of HHT in the paper. The technique of HHT is proved to be effective on processing and distinguishing the differences of the non-stationary signals.

For the original non-stationary signals of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange given here, the obtained IMFs with HHT are easily distinguished from each others. The frequency spectra are also different between them. These results demonstrate that the HHT can offer a new and more effective way for identifying the different features of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange.

Keywords: Epanechnikov mixture model; Fuzzy model; Stock index.

Abstract. In this paper, the mathematical equivalence between the conditional mean of a Epanechnikov mixture model (EMM) and the defuzzified output of a rule-centered generalized fuzzy model (RCGFM) is derived theoretically. Our results provide a new perspective for fuzzy systems, i.e., interpreting them from a probabilistic viewpoint. Thus, instead of directly estimating the parameters of the fuzzy rules in a rule- centered generalized fuzzy model, we can first estimate the parameters of the corresponding EMM using any popular density estimation algorithm like the expectation maximization (EM) algorithm. Our experimental results clearly indicate that a rule-centered generalized fuzzy model trained in such a new way has higher approximation accuracy and generalization ability than other models.

Introduction

In [1], a novel technique regarding fuzzy modeling was proposed using a kind of probabilistic system, namely the Gaussian mixture model (GMM). Gan and Hanmandlu proved the mathematical equivalence between the condition mean of GMM , and the defuzzified output of generalized fuzzy model (GFM)[2]. They built a bridge between probability theory and fuzzy logic. The proposed modeling method lacks interpretability without taking into consideration the correlation among components of sample data, but is less time-consuming. A major advantage is that their results provide a study of the new perspective of fuzzy model by interpreting a fuzzy system from a probabilistic viewpoint.

In [3], Janos Abonyi et al. proposed a new fuzzy modeling algorithm which partitioned the input space more effectively than conventional fuzzy modeling algorithms by taking into consideration the correlation among components of sample data. The main advantage of the proposed method is that it yields compact and easily manageable fuzzy models. However, the algorithm is only suitable for the low dimensional case as a result of calculating the complicated eigenvalue of matrix.

In [4], M. Bikdash presented a new form of fuzzy inference systems (FIS) that was highly interpretable and easy to manipulate. The new form is based on a judicious choice of membership functions that have strong locality and differentiability properties and on a modification of the Sugeno and generalized Sugeno forms of the consequent polynomials as to make them rule-centered. Under these conditions, the coefficients in the consequent polynomials can be exactly interpreted as Taylor series coefficients. This increased interpretability bridges the gap between the linguistic and computational interpretations of fuzzy inference systems with great benefit to both. A major advantage, is that the rudiments of the calculus of fuzzy inference systems begin to emerge.

In [5], Dorin Comaniciu and Peter Meer proved the Epanechnikov kernel was the optimal kernel and yielded minimum mean integrated Square Error(MISE). This paper followed the example of GMM in establishing Epanechnikov mixture model (EMM) that repalced Gaussian kernel function with Epanechnikov kernel function.

In this paper, a new fuzzy modeling algorithm combining the advantages of [1], [3] and[4] is proposed: it is inspired by EMM, and avoids their disadvantages. The proposed model takes into consideration the correlation among components of sample data with a small number of fuzzy rules as well as Abonyi's model [3], is as easy to implement as Gan and Hanmandlu's[1] and highly

interpretable like Bikdash's[4]. The suggested model has the same structure as that of Azeem's model [2] and its identification mimics the simple identification procedure of Gan and Hanmandlu's one [1].

Rule-centered generalized fuzzy model with multidimensional and correlational membership functions(RCGFM-MCMF)

Generally speaking, fuzzy models are superior to linear models in capability to represent a given unknown system. In this chapter, RCGFM-MCMF is proposed based on the three models [2,3,4].

RCGFM-MCMF combines the merits and removes the demerits of the above three fuzzy models. RCGFM-MCMF rules and output can be represented as follows:

$$R_k: \text{If } x \text{ is } A_k(x), \text{ then } y \text{ is } B_k(f_k(x), v_k) \text{ and } y^o = \frac{\sum_{k=1}^{M} v_k \cdot A_k(x) \cdot f_k(x)}{\sum_{k'=1}^{M} A_{k'}(x) \cdot v_{k'}} \quad (1)$$

Where M is the number of rules, v_k is the index of fuzziness, $R_k(k=1,2,\cdots,M)$ denotes the k th fuzzy rule, $x=(x_1,x_2,\cdots,x_J)^T$ is the input vector and $A_k(x)$ is the multidimensional membership function defined on x. $f_k(x)$ is the varying centroid and has the following form:

$f_k(x)=b_0^k+b_1^k(x_1-r_1^k)+\cdots+b_J^k(x_J-r_J^k)$, where $r_k=(r_1^k,r_2^k,\cdots,r_J^k)$ is the k th rule center.

In the proposed framework, the partitioning of the input space is realized by means of multivariable fuzzy sets with taking into account the correlation among data components. Better accuracy was achieved than other models. The special form of $f_k(x)$ possesses a high degree of interpretability which follows from that of the coefficients of the consequent polynomials.

From EMM to RCGFM-MCMF

Let the input vector be x with dimensions $J(\mathrm{J}>1)$, and the output be y. The first J variables x form the input vector while the $(J+1)$ th variable is the output y. We can give the form of EMM according to GMM as follows:

$$G(x,y)=\sum_{k=1}^{C} p_k G_{(J+1)\mathrm{k}}\left(\begin{bmatrix}x\\y\end{bmatrix};\begin{bmatrix}\mu_{kx}\\\mu_{ky}\end{bmatrix},\Sigma_k\right) \quad (2)$$

where, $G_{(J+1)\mathrm{k}}\left(\begin{bmatrix}x\\y\end{bmatrix};\begin{bmatrix}\mu_{kx}\\\mu_{ky}\end{bmatrix},\Sigma_k\right)$ is the k-th component multivariate Epanechnikov kernel functions.

With $G(x,y)$, it is possible to estimate the expected value y_e. y_e is given

$$y_e=E(y|x)=\int_{-\infty}^{+\infty} yG(y/x)dy=\frac{\int_{-\infty}^{+\infty} yG(x,y)dy}{G(x)}=\frac{\int_{-\infty}^{+\infty} yG(x,y)dy}{\int_{-\infty}^{+\infty} G(x,y)dy} \quad (3)$$

The marginal probability density function (pdf) of the k th term of $G(x,y)$ is given by

$$G_{Jk}(x)=\begin{cases}\dfrac{4F^3}{3V_J(\sigma^{kyy})^2} & A^2-\sigma^{kyy}B+\sigma^{kyy}K^2\geq 0\\ 0 & otherwise\end{cases} \quad (4)$$

where $(x-\mu_{ky})^T\sigma^{kxy}=A$, $(x-\mu_{kx})^T\sigma^{kxx}(x-\mu_{kx})=B$ and $F=(\sigma^{kyy}K^2-\sigma^{kyy}B+A^2)^{\frac{1}{2}}$.

Hence, the marginal pdf of x is

$$G(x)=\int_R G(x,y)dy=\sum_{k=1}^{C} p_k G_{Jk}(x) \quad (5)$$

We can derive

$$\int_R yG_{(J+1)\mathrm{k}}\left(\begin{bmatrix}x\\y\end{bmatrix};\begin{bmatrix}\mu_{kx}\\\mu_{ky}\end{bmatrix},\Sigma_k\right)dy=\frac{4F^3}{3V_J(\sigma^{kyy})^2}\left(\mu_{ky}-\frac{(x-\mu_{kx})^T\sigma^{kxy}}{\sigma^{kyy}}\right) \quad (6)$$

By (2), (4) and (6), we have

$$\int_R yG(x,y)dy = \sum_{k=1}^{C} p_k G_{Jk}(x)(\mu_{ky} - \frac{(x-\mu_{kx})^T \sigma^{kxy}}{\sigma^{kyy}}) \tag{7}$$

Substituting (5) and (7) into (3), we obtain

$$y_e = \frac{\sum_{k=1}^{C} p_k G_{Jk}(x)(\mu_{ky} - \frac{(x-\mu_{kx})^T \sigma^{kxy}}{\sigma^{kyy}})}{\sum_{k'c=1}^{C} p_{k'} G_{Jk'}(x)} \tag{8}$$

Note that (8) is similar in form to (1), and both are equivalent if the following conditions are true.

Theorem 1: (8) and (1) are equivalent under the following conditions:

I. The number of rules, M , in the RCGFM rule base, equals the number of components, C , in the EMM, i.e., $\boxed{M = C}$.

II. he weight of each rule, υ_k , is given by the corresponding prior of the mixture model p_c, i.e., $\boxed{p_k = v_k}$

III. The regression function in the THEN-part of the RCGFM rules is linear, and is a function of all input variables, given by $\boxed{f_k(x) = \mu_{ky} - \frac{(x-\mu_{kx})^T \sigma^{kxy}}{\sigma^{kyy}}}$

IV. The membership function in the IF-part of the RCGFM rules, $A_k(x)$, is a generalized Epanechnikov function with mean μ_{cx} and variance σ_{cxx} , i.e., $\boxed{A_k(x) = G_{Jk}(x).}$

V. The fuzzy system is additive, with multiplicative conjunction and implication.

These are the conditions under which there is mathematical equivalence between the output of a RCGFM and the expected output of a EMM. What this means is that for any MISO system whose input-output joint probability distribution is known to be a Epanechnikov mixture, there exists, under the above five condisions, a fuzzy system which equivalently models its expected output. The new fuzzy system that is obtained from EMM is named as EMM-inspired RCGFM (EMM-I- RCGFM).

Applications

In this section, we validate the effectiveness and efficiency of the proposed EMM-I-RCGFM algorithm by comparison with GM Markov Model [6] on Shanghai composite index,.

To quantify the performance of the resulting EMM-I-RCGFM , we use the performance measure found in [7], which is a form of the mean squared error (MSE) function. The performance measure MSE is expressed by the formula: $MSE = \frac{\sum_{n=1}^{N} e^2(n)}{N \cdot y_r}$, where $N =$ total number of data; $e(n) = y_{target} - y_{forecast}$; $y_r = [\max(y_{target}) - \min(y_{target})]^2$.

We choose the Shanghai composite index (daily closing price) between January 5, 2009 and December 30, 2011 as historical data, and choose the Shanghai composite index between January 4, 2012 and March 29, 2013 as verification data. There is a total of 1025 observations.

Fig. 1 plots the target output (solid line) and the model output (dotted line), due to very small values of model error at each point, the dotted line has been almost completely hidden by the solid line.

Fig. 2 plots the target output and predicted output. As can be observed, even with the validation data, the proposed RCGFM has captured the characteristic and nuances of the Shanghai composite index. The shape of the predicted output plot follows the target output plot reaonably well.

Tabel 1 shows the experiment results of EMM-I-RCGFM and GM Markov Model. According to Tabel 1, the performance of EMM-I-RCGFM seems superior to GM Markov Model. Hence, it is clear that EMM-I-RCGFM works efftively in the forcast of Shanghai composite index.

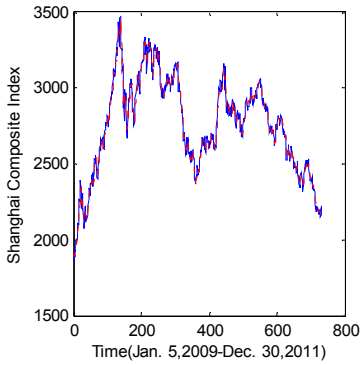

Fig. 1 Comparison of model outputs, original output data for the historical data of Shanghai composite index.

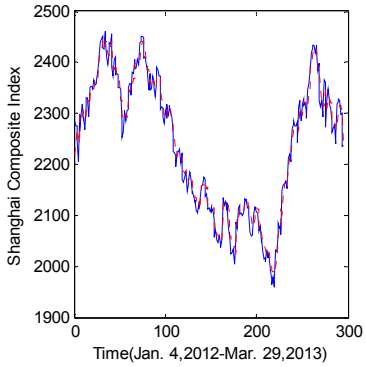

Fig. 2. Comparison of model outputs, original output data for the test data of Shanghai composite index

Table1 Performance comparison of different models for the test data of Shanghai composite index

Models	MSE
EMM-I-RCGFM	0.0019
GM Markov Model	0.0996

Conclusions

We have presented the theory and design of EMM-I-RCGFM. The parameters of RCGFM is computed using an efficient and simple probabilistic method. EMM-I- RCGFM provides a new viewpoint to design fuzzy system by probabilistic system. EMM-I-RCGFM has a markedly high interpretability stemmed from Epanechnikov kernel function and rule-centered consequent polynomials. The rule-centered consequent polynomials can be interpreted as the truncated Taylor series expansions of model output at rule center. EMM-I- RCGFM has taken into consideration the correlation among components , which resulted in an ineffective partition of the input space.Finally, the proposed fuzzy model has been used on stock applications: The results demonstrate the superiority of this model over other model in accuracy and generalization ability. Thus this paper makes an important contribution to the field of fuzzy modeling by introducing probabilistic and calculus theory into fuzzy model for dealing with real-life applications.

A Multifactor grey forecasting model of agriculture output value

Weizhen Chen[a], Lijuan Liang[b]
School of Electrical and Electronic Engineering，Wuhan Polytechnic University Wuhan 430023, China
[a]email: chenwz_2005@126.com, [b]email: 79108730@qq.com

Keywords: Multifactor; Grey forecasting model; Poor information; Agriculture output value.

Abstract. In this paper, a multifactor grey forecasting model of agriculture output value is proposed. Agriculture output value is very important in the country. It can help us to well know the situation of agriculture, and to modify the policy of agriculture. When the data change greatly, one-factor forecasting model may not be get good results. Grey forecasting model with multifactor would be better. From the simulation, this multifactor grey forecasting model with gross and total farm output value can get better effects.

Introduction

Agriculture output value is very important in the country. It can help us to well know the situation of agriculture, and to modify the policy of agriculture. As we all known, the perfect way to control the agriculture situation is to get forecasting value. That means, finding the appropriate forecasting model is a significant thing for agriculture planning. Agriculture output value can be gotten every year. How to use these values to construct the forecasting model is still a problem in this field. Although, agriculture output value can be gotten every year, it is difficult to describe the changes. The latest data should be more helpful to find the relevant between the past data and the future data. In this opinion, agriculture output forecasting value is still belong to poor information problem. Using grey system theory with multifactor may be expected to get good results.

Recently thirty years, grey system theory has been a quick development in china[1-6], and both the theory and practical applications of grey systems have achieved splendid results. This theory has been successfully applied in many scientific fields and various human endeavors. Relative to usual model, a grey system is a system with “poor” information. An excessively complex or complicated object, which generally shows a lack of completed model information, may be looked upon as a grey system.

In this paper, a multifactor grey forecasting model of agriculture output value is proposed. Based on multifactor to make grey forecasting model better. From the simulation, this multifactor grey forecasting model can get good effects.

A multifactor grey forecasting model

A grey system is a system with “poor” information. When analyzing grey problems, we try to see their own characteristics as a system through generating operation rather than finding their statistical features or probability distributions, and may find their latent laws through the integral generating transform(IGT for short) and Trend relational Analysis(TRA for short).When analyzing bridge-health forecast problem, we try to see it own characteristics as a system through generating operation rather than finding it statistical features or probability distributions, and may find it latent law through the IGT.

Based on mean-value, $SCGM_{mv}(1,h)$ has been propose several years before. In fact, $SCGM_{mv}(1,1)$ always has been used. That is to say, these forecasting model were built with one-factor[7-10] .

It is assumed that only a few of the discrete data observed from agriculture output values. such as $X_i^{(0)} = \{X_i^{(0)}(k) \mid X_i^{(0)}(k) \geq 0, k = 1,2,..., n\}$ $= (X_i^{(0)}(1), X_i^{(0)}(2), \dots, X_i^{(0)}(n)), i = 1,2,\dots,h$ which is called the original time series corresponding

to $X^{(0)}(t) \in X(\otimes,t)$. Now, it is required that a system model is established for agriculture output value forecasting. Taking the mean-value generating transform, we have the mean-value generating time series:

$$\overline{X}_i^{(0)} = (\overline{X}_i^{(0)}(2), \overline{X}_i^{(0)}(3), \ldots, \overline{X}_i^{(0)}(n))$$

$$\overline{X}_i^{(0)}(k) = 0.5[X_i^{(0)}(k) + X_i^{(0)}(k-1)], \qquad k = 2,3,...,n; i = 1,2,...,h.$$

According to the principle of grey dynamic modeling, if $\overline{X}_i^{(0)}$ tendency is satisfactorily related to the non-homogeneous exponential function with respect to discrete time, then the grey model of system cloud, denoted by $SCGM_{mv}(1,h)$ model of agriculture output value forecasting, can be constructed as

$$\dot{\hat{X}}^{(0)}(t) = \hat{A}\hat{X}^{(0)}(t) + \hat{U}, t \geq 0$$

and its solution (forecasting model) is

$$\hat{X}^{(0)}(t) = \underline{\hat{A}}^t \underline{\hat{B}} - \underline{\hat{C}}$$

or

$$\hat{X}^{(0)}(k) = \underline{\hat{A}}^{k-1} \underline{\hat{B}} - \underline{\hat{C}}$$

where

$$\underline{\hat{A}} = \underline{X}_{k+1}^T \underline{X}_k (\underline{X}_k^T \underline{X}_k)^{-1}$$

$$X_{k+1} = \begin{bmatrix} X_1^{(0)}(4) - X_1^{(0)}(2) & X_2^{(0)}(4) - X_2^{(0)}(2) & \cdots & X_h^{(0)}(4) - X_h^{(0)}(2) \\ X_1^{(0)}(5) - X_1^{(0)}(3) & X_2^{(0)}(5) - X_2^{(0)}(3) & \cdots & X_h^{(0)}(5) - X_h^{(0)}(3) \\ \vdots & \vdots & & \vdots \\ X_1^{(0)}(n) - X_1^{(0)}(n-2) & X_2^{(0)}(n) - X_2^{(0)}(n-2) & \cdots & X_h^{(0)}(n) - X_h^{(0)}(n-2) \end{bmatrix}$$

$$X_k = \begin{bmatrix} X_1^{(0)}(3) - X_1^{(0)}(1) & X_2^{(0)}(3) - X_2^{(0)}(1) & \cdots & X_h^{(0)}(3) - X_h^{(0)}(1) \\ X_1^{(0)}(4) - X_1^{(0)}(2) & X_2^{(0)}(4) - X_2^{(0)}(2) & \cdots & X_h^{(0)}(4) - X_h^{(0)}(2) \\ \vdots & \vdots & & \vdots \\ X_1^{(0)}(n-1) - X_1^{(0)}(n-3) & X_2^{(0)}(n-1) - X_2^{(0)}(n-3) & \cdots & X_h^{(0)}(n-1) - X_h^{(0)}(n-3) \end{bmatrix}$$

$$\underline{\hat{B}} = 2(I + \underline{\hat{A}}^{-1})^{-1} \underline{\hat{B}}$$

$$\underline{\hat{B}} = \left[(n-1) \sum_{k=2}^{n} \left(\underline{\hat{A}}^{k-1} \right)^T \underline{\hat{A}}^{k-1} - \left(\sum_{k=2}^{n} (\underline{\hat{A}}^{k-1})^T \right) \left(\sum_{k=2}^{n} \underline{\hat{A}}^{k-1} \right) \right]^{-1} \cdot$$

$$\left[(n-1) \sum_{k=2}^{n} \left(\underline{\hat{A}}^{k-1} \right)^T \overline{X}_{0.5}^{(0)}(k) - \left(\sum_{k=2}^{n} (\underline{\hat{A}}^{k-1})^T \right) \left(\sum_{k=2}^{n} \overline{X}_{0.5}^{(0)}(k) \right) \right] \quad \underline{\hat{C}} = \frac{1}{n-1} \left[\left(\sum_{k=2}^{n} \underline{\hat{A}}^{k-1} \right) \underline{\hat{B}} - \sum_{k=2}^{n} \overline{X}_{0.5}^{(0)}(k) \right]$$

$$\hat{A} = \ln \underline{\hat{A}}, \quad \hat{U} = \hat{A}\underline{\hat{C}}, \quad \hat{X}^{(0)}(1) = \underline{\hat{B}} - \underline{\hat{C}}$$

Demonstrating experiment

A. One-factor grey forecasting model

Agriculture output data can be gotten from Chinese Western statistical yearbook. Here we use the gross output value and total value of farm output in Nei Monggol province. From mass data(1991-1995) obtained, the approximate function will be found, and forecasting value in 1996 will be estimated. In the table 1, the test values are gross output from 1991 to 1995, and the forecasting value in 1996 is estimated.

Table 1. Results of gross output forecasting value(million yuan)

Year	Gross output value	Forecasting value	Error
1991	1065704	982342	-7.8%
1992	1194970	1177809	-1.4%
1993	1353978	1490980	10.1%
1994	2121949	1992732	-6.1%
1995	2694508	279.6621	3.8%
1996	3073205	4084584	33.0%

$SCGM_{mv}(1,1)$ forecasting model: $\hat{X}^{(0)}(k)=\hat{\underline{a}}^{k-1}\hat{\underline{b}}-\hat{\underline{c}}=(16022)^{k-1}\times(324608)-(-657733)$

In the table 2 the test values are total farm output from 1991 to 1995, and the forecasting value in 1996 is estimated.

Table 2. Results of total farm output forecasting value (million yuan)

Year	Total farm output value	Forecasting value	Error
1991	763191	704206	-7.7%
1992	871291	855948	-1.8%
1993	991439	1096595	10.6%
1994	1579087	1478233	6.4%
1995	2002403	2083468	4.0%
1996	2352458	3043300	29.3%

$SCGM_{mv}(1,1)$ forecasting model: $\hat{X}^{(0)}(k)=\hat{\underline{a}}^{k-1}\hat{\underline{b}}-\hat{\underline{c}}=(15859)^{k-1}\times(258998)-(-445208)$

Using one-factor grey forecasting model, the forecasting value is not satisfied. The result of test data maybe well, but the forecasting value in 1996 is not good. The reason is the test data changing greatly. In view of this situation one-factor grey forecasting model may not be used well.

B. Multifactor grey forecasting model

Based on relevant between multifactor, more information could be mined. Multifactor grey forecasting model is used here. In the table 3, the test values are gross output and total farm output from 1991 to 1995, and the forecasting value in 1996 is estimated.

Table 3. Results of gross and total farm output forecasting value(million yuan)

Year	Gross output forecasting value	Error of gross output forecasting value	Total farm forecasting value	Error of total farm forecasting value
1991	1139608	6.9%	821659	7.7%
1992	1121066	-6.2%	812823	-6.7%
1993	1427882	5.5%	1049907	5.9%
1994	2048045	-3.5%	1520619	-3.7%
1995	2768412	2.7%	2060871	2.9%
1996	3196688	4.0%	2373379	0.9%

From table 3, less error would be gotten. That means, using multifactor grey forecasting model with agriculture output value maybe achieved better results. The effects of two different grey forecasting models are be compared by errors. Obviously, the effects of multifactor grey forecasting model is better. The error value of gross output forecasting decreased for 33.0% to 4.0%. The error value of total farm output forecasting decreased for 29.3% to 0.9%.

$SCGM_{mv}(1,2)$ forecasting model:

$$\hat{X}^{(0)}(k)=\hat{\underline{A}}^{k-1}\hat{\underline{B}}-\hat{\underline{C}}$$

$$\hat{\underline{A}}=\begin{bmatrix}483534 & -358297\\ 626963 & -464257\end{bmatrix},\ \hat{\underline{B}}=\begin{bmatrix}-395052\\ -521864\end{bmatrix},\ \hat{\underline{C}}=\begin{bmatrix}-1216711\\ -1661472\end{bmatrix}$$

From the result, it can get better estimate value and less error.

Conclusions

Although agriculture output value can be gotten every year, the forecasting model still hard to be constructed in this situation. It is difficult or impossible to describe this complicated system. Generally, forecasting models always have been built up by one-factor. In this paper, multifactor have been used and a multifactor grey forecasting model has been proposed. Using relevant of multifactor, better result can be achieved. From the simulation, the effects of two different grey forecasting models are be compared by errors. Obviously, the effects of multifactor grey forecasting model is better.

Keywords: Demodulation, PCM/FM, MSD

Abstract. Based on maximum likelihood, research a new based on Symbol Detection (Multi-Symbol Detection, MSD) soft demodulation method of PCM/FM telemetry signals. Introduced the basic principle of the demodulation method and the implementation process, analyzed the demodulation and synchronization factors and formulate the corresponding synchronization strategies.

Introduction

With the development of modern remote sensing system as well as to the requirement of signal post-processing is increasing, the demand for software to resolve tuning is becoming more and more urgent. Software signal demodulation greatly widened the signal receiving and processing system solutions, for software radio, signal processing provides an effective way. Of non-stationary random signal processing usually adopts the time-frequency analysis methods, such as proposed in the literature [1][2] FM signal demodulation method based on STFT and WD, although the noise resistance and resistance to fall excellent performance, but the computation is very big, takes a long time, is not conducive to real-time processing software.

1 Algorithms of MSD

Is not zero in PCM/FM (NRZ PCM/FM) is a kind of hybrid coding and modulation mode, used to send digital signal transmission line. This method is to use high frequency shift formula one Hertz carrier on behalf of the binary "1" state, low frequency shift f0 Hertz carrier on behalf of the binary "0" state.PCM/FM signal in the field of remote sensing is known as the continuous phase frequency shift keying (CPFSK) signals, and its mathematical expression is:

$$S(t) = A\cos\left[2\pi(f_c + f_d)t + K_m \int f(t)dt\right] \tag{1}$$

$$\phi(t;a) = \pi h \sum_{k=-\infty}^{n-l} a_k + 2\pi h a_n q(t - nT) \qquad (nT \le t \le (n+1)T) \tag{2}$$

This shows that the PCM/FM signal instantaneous phase is equal to the original on the basis of the instantaneous phase and the phase change from the current element.PCM/FM signal, therefore, is the symbol between before and after the phase of memory, and traditional demodulation methods did not use this information.MSD is based on the idea of maximum likelihood estimation, the use of symbols between before and after the memory, a multiple symbols for maximum likelihood detection. Its central idea is: the bit-rate received a signal that is not an immediate decision, but to continue to observe the following several yards after code, through the code of several code sequence estimation, on the whole sequence.

According to the core of the MSD, the MSD algorithm simulation concept description is as follows:

As a first step, according to the parameters of the signal, and observation of MSD length N, generating all possibility 2 N kind of local phase meter, and the corresponding modulation signal baseband sample, forming a series of related receiving channel, this paper will be off for observation length N = 5.

The second step, through telemetry channel receiving signals for digital quadrature down-conversion, it is advantageous to the carrier tracking, at the same time be able to get two I/Q signal component, which contains the signal phase information, and the I/Q phase two road rough adjustment in time domain, makes the frequency filter to the I/Q two-way signal shift effect to adjust to a symbol scope.

Third step, the next two road I/Q signal after frequency conversion merged into complex envelop form, the complex envelop are associated with the local sample signals of each channel operation, from the various channels selected related calculation is a maximum likelihood of the corresponding channel number.

The fourth step, find local code set of tables, the output channel number corresponding theory frame as the demodulation results.

According to the above derivation, MSD algorithm core operation flow, as shown in figure 1.

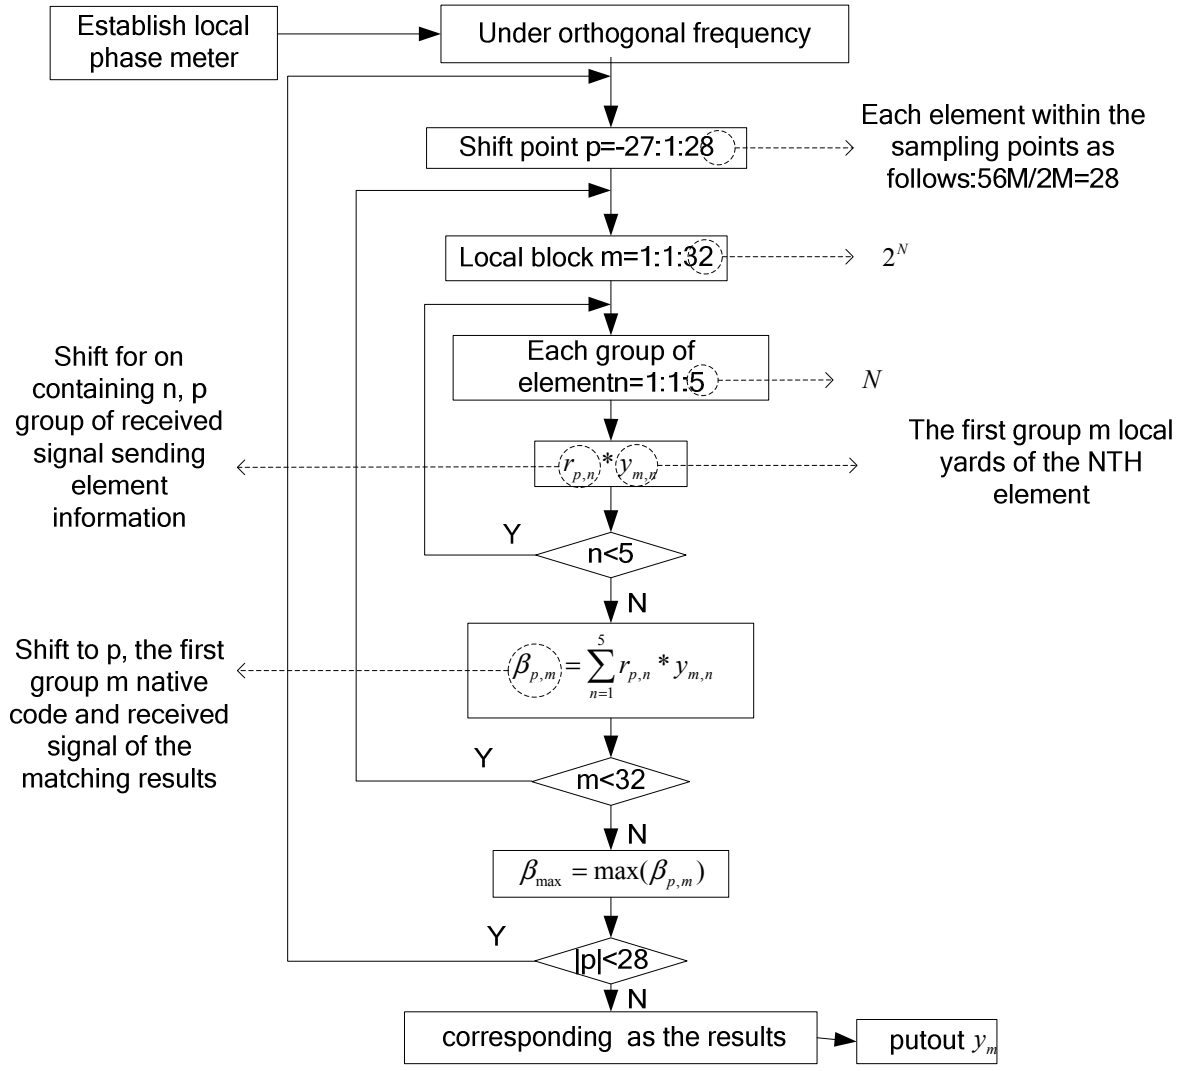

Fig 1 MSD algorithm simulation core operation flow.

2 Carrier synchronization

Received signal expression is:

$$r(t)=s(t)+n(t)=Ae^{j(\Delta wt+\theta+\pi h\sum_{k=-\infty}^{n-1}a_k+2\pi ha_n\frac{t-nT}{2T})}+n(t) \tag{3}$$

With deviation of received signal generation into the likelihood value expressions, eventually maximum likelihood values can be obtained and the relation between the frequency offset is as follows:

$$\beta_{\max}(\omega)=\frac{1}{N}\left|\int_{(n-N+1)T}^{(n-1)T}e^{\omega tj}dt\right| \tag{4}$$

The rise and fall of the final design frequency carrier synchronization block diagram is shown in figure 2.

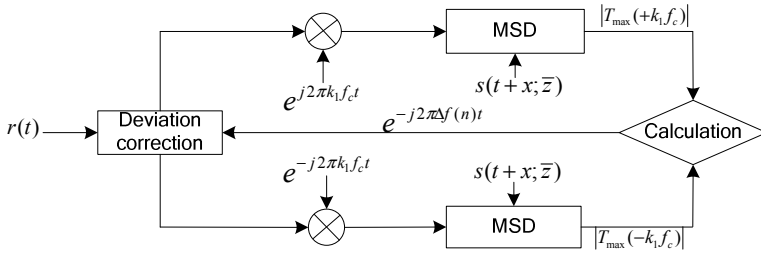

Fig 2 Based on the MSD deviation compensation principle diagram

Because of MSD is a kind of phase correlation algorithm, so the existence of time delay will also affect the phase, which affect the MSD. With similar carrier synchronization, by transforming the received signal with a delay expression generation into the likelihood value expressions can be eventually likelihood value and the relation between the time delay is as follows:

$$\left|\beta(\mathbf{a},r(t-T))\right|=\begin{cases}N\left|(\frac{1}{2}T-\frac{\Delta T}{4})\cos(\pi h\frac{\Delta T}{T})+\frac{T}{4\pi h}\sin(\pi h\frac{\Delta T}{T})\right|, 0\le\Delta T\le\frac{T}{2}\\ N\left|\frac{1}{4}(T+\Delta T)\cos(\pi h\frac{T-\Delta T}{T})+\frac{T}{4\pi h}\sin(\pi h\frac{T-\Delta T}{T})\right|, \frac{T}{2}\le\Delta T<T\end{cases} \tag{5}$$

Design a kind of time synchronization algorithm to synchronize time delay, similar to that in figure 2.

3 Algorithm performance.

The classical synchronization correction step is divided into fixed step length and step length. Cycle time deviation is 0.05 times the selected code, frequency deviation is 0.01 times the rate of synchronization precision as a threshold, when the synchronization error is lower than the threshold that enters the lock, bit error rate after enter lock area compared with the complete lock bit error rate of error is very small, the simulation results of fixed step length and variable step as shown in figure 3 and 4, respectively.

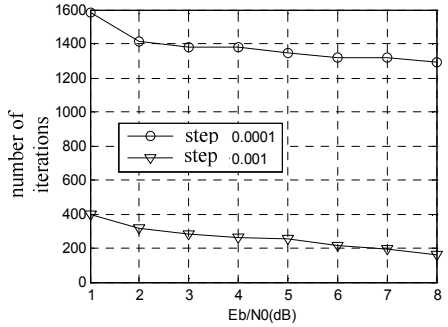

Fig 3 Fixed time step into the lock

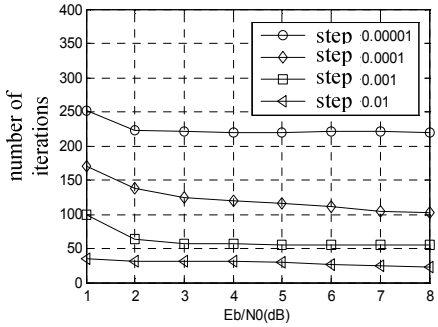

Fig 4 Variable time step into the lock

As shown in figure 3, the lock time and iterative step become inverse ratio, the iteration step length that synchronization of the required number of iterations increases, the iteration step length is 0.001 times the bit rate, the steps needed for synchronization iterative step is about 100; Iteration step length is 0.0001 times the bit rate, the steps needed for synchronization iterative step is about 1000, in the early time increase rapidly. To increase the capture speed, select the variable step parameter set, using smaller length L, smaller small scale fluctuation corresponding decision parameters k_1, smaller continuous motion corresponding decision parameters k_2, moreover the iteration step length increase rate should be greater than less.

Through the study of MSD algorithm and demodulation synchronization method, the following will be demodulation performance test of the entire software demodulation system. Signal intensity were 10.45 dB and 8.18 dB and 4.62 dB, then the MSD system software demodulation and the final error rate, and then with the hardware of MSD demodulation and STFT method and traditional method of frequency demodulation performance comparison, the article demodulation performance results in the diagram as shown in figure 5.

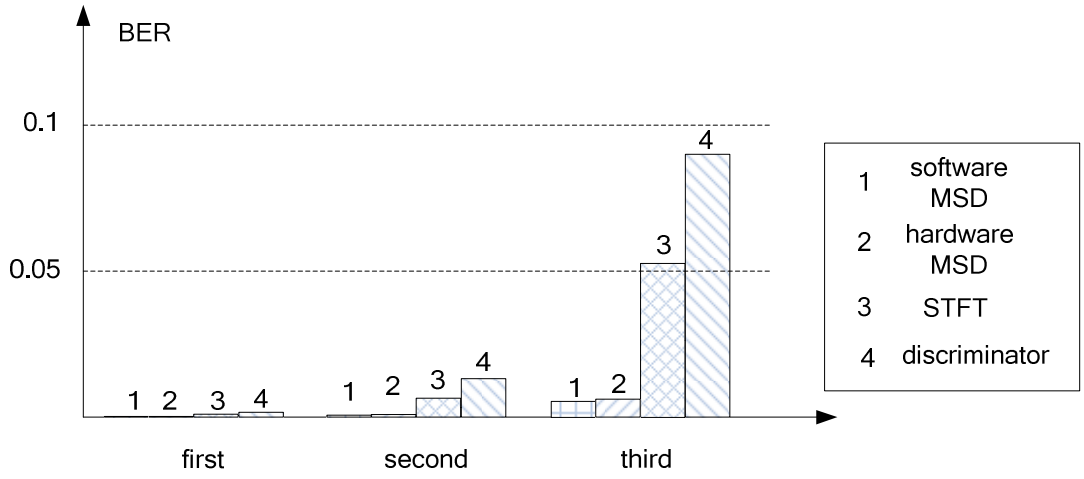

Fig 5 A comparison error rate

See from figure 5 can be more intuitive, MSD method of BER performance is far better than short time Fourier transform (STFT) [3]and the frequency discrimination laws, and get the bit error rate of MSD after demodulation software and hardware method (MSD) BER is after demodulation, consistent with the expected results of the test, software demodulation algorithm is practical and feasible, the demodulation results.

Summary

This article uses the symbol detection more demodulation method and the corresponding synchronization method to build the software demodulation system, verified by measured data was tested, the results show that the method of demodulation performance is very good, in line with expectations.

Keywords: Action recognition, silhouette, optical flows, mixed characteristics, leave one out, improved algorithm.

Abstract. The choice of the motion features affects the result of the human action recognition method directly. Many factors often influence the single feature differently, such as appearance of human body, environment and video camera. So the accuracy of action recognition is limited. On the basis of studying the representation and recognition of human actions, and giving full consideration to the advantages and disadvantages of different features, this paper proposes a mixed feature which combines global silhouette feature and local optical flow feature. This combined representation is used for human action recognition.

Introduction

Human action recognition based on video is one of the important research directions in video analysis, which belongs to the low level of computer vision, having broad application prospects in the field of video surveillance, video retrieval, human-computer interaction, virtual reality, etc.

In the video sequence, motion information can usually use optical flow, silhouettes, points of interest and other features to describe. Document [1]proposed to use optical flow histogram to describe the motion information, and then using support vector machine classifier to identify players batting action. Optical flow representation can, without any prior knowledge of the background region, realize the detection and tracking of moving object; but the drawback is that it is not only greatly affected by noise and changes of light intensity, but also has a complex calculation method and large amount of calculation. Based on silhouette image, literature[2]divides moving target into vehicle, the human body and the crowd through extracting the distance feature from centroid to boundary points. Description method based on sketch is easy to realize and slightly affected by the illumination condition, but it is mainly dependent on the shape of the boundary information, cannot obtain the internal structure and easily affected by the background variation. In literature[3], standard body posture silhouette image is scaled into m*n sub block. By calculating the number of pixels in each sub block body of all sub pixels, it can count the maximum proportion to the analysis of human behavior. This method describes the silhouette of internal information and has simple calculation, too. But it is sensitive to the changes of angle and behavior.

Features Expression and Extraction

Image Preprocessing. Image processing can reduce the image area and process data of the study, which could reduce the amount of computation. Usually using background subtraction method to determine the approximate region of human body movement and the silhouette, as is shown in Figure 1 (b). Assuming that all action is performed in the static background, based on silhouette information, we can determine the region of interest is as shown in Figure 1 (c). After region of interest is determined, we can only process the information in region of interest.

Fig. 1. (a) Video in the Original Image; (b) The Human Body Silhouette; (c) Marked the Original Image (the green rectangular box is for region of interest)

Silhouette Feature Expression and Extraction. Single frame images of human silhouette can be used to describe the overall shape change information of human motion. The silhouette feature has following advantages: ① silhouette feature can provide simple and intuitive description of moving human shape; ②silhouette feature can be easily extracted; ③two-value silhouette is not sensitive to the image texture and color of foreground silhouette [4]. The purpose of this step is to convert motion information of original video into the associated morphological characteristics sequence which reflects the changes of the movement process.

Provided with a section of video T frame images such as I, $V = [I_1, I_2, \dots, I_T]$, moving silhouette sequence corresponding to $S = [S_1, S_2, \dots, S_T]$, S, have been obtained in the image preprocessing. For the sake of simplicity, we used the method of vector [5] to describe the overall shape of the contour information of human silhouettes. The detailed process is as follows:

Edge profile of each frame silhouette can be obtained by using canny operator, as is shown in Figure 2 (a). And the coordinate representation of edge profile can also be acquired, as is shown in Figure 2 (b). So the body contour can be expressed by n_t points, i.e.:

$\{(x_1, y_1), (x_2, y_2), \dots, (x_{n_t}, y_{n_t})\}, \quad t = 1,2,3, \dots, T$

The centroid of body contour can be obtained by formula (1).

$$(x_c, y_c) = \left[\frac{1}{n_t}\sum_{i=1}^{n_t} x_i, \frac{1}{n_t}\sum_{i=1}^{n_t} y_i\right] \quad (1)$$

Among which, (x_c, y_c) is the center, $(x_i, y_i)$is for edge point, n_t is the total number of edge profile in t image.

The distance from centroid to edge point can be obtained by formula (2):

$$d_i = \sqrt{(x_i - x_c)^2 + (y_i - y_c)^2}, i = 1,2, \dots, n_i \quad (2)$$

d_i is the distance of the corresponding centroid of the i edge point to edge point. Starting with the leftmost top point of contour record when doing the calculation, which should be the clockwise calculation, so we can get corresponding one-dimensional profile vector D_t from two-dimensional contour record of single frame image I_t.

$$D_t = [d_1, d_1, d_1, \dots, d_1, \dots, d_1,], i = 1,2, \dots, n_t \quad (3)$$

Feature Expression and Extraction of Optical Flow. Inaccurate silhouette image extraction may cause that the profile vector feature information could not accurately express action features. At this time, flow characteristics can accurately express the action information in video sequences. Extracting optical flow in movement region, and using local optical flow information of sub region to represent local features of human movement, can improve the anti-noise capability of optical flow. The specific process of optical flow extraction and expression is as follows:We can determine the position of the corresponding interest region of current frame image I_t, and shear the corresponding gray scale image region to the position of current frame and previous frame image to the region of interest, as is shown in Figure 3 (a1), (a2). Then we can use the method of Lucas -Kanade for optical flow detection in region of interest in current and previous frames. The optical flow field is shown in Figure 3 (b), the optical flow is decomposed into 2 components of vertical and horizontal, i.e. vertical flow, transverse flow.

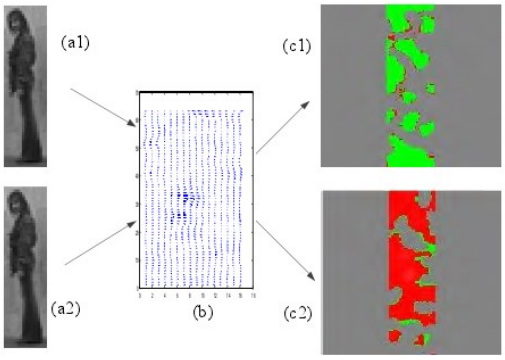

Fig. 3. (a1) Gray Level Image of t-1 Region of Interest Image;(a2) Gray Level Image of Interest Region at t Moment; (b) The Optical Flow Field at Time t（the optical flow field is divided into vertical and horizontal directions）; (c1) is for the longitudinal optical flow chart; (c2) is for the horizontal flow chart

In order to reduce the optical flow information dimension, find the identification ability of data expression, we can use the sub regional radial histogram method to count optical flow characteristics .

Firstly, according to the premise of the zoomed long side, the optical flow image will be standardized into the optical flow diagram in 120*120 dimensional unified sizes. As is shown in Figure 3 (c1), (c2).

The normalized optical flow diagram is divided into 2*2 sub frame S_1, S_2, S_3, S_4, which is in size of 60*60. The center points are respectively C_1, C_2, C_3, C_4, as is shown in Figure 4 (a). And then taking the center point of sub frames as the center, we can divide sub frame into 18 sub regions which are respectively $S_{i1}, S_{i2}, \dots, S_{i18}, i = 1,2,3,4$, as is shown in Figure 4 (b). Each central angle is of 20 degrees, so that 72 sub regions are forming[9].

The optical flow information of the whole image I_t can be expressed by the longitudinal and transverse flow O_L and H_L of 72 sub regions, such as is shown in type (4), (5), and (6).

$$O_L = [O_{L1,1}, \dots, O_{L1,18}, \dots, O_{L4,1}, \dots, O_{L4,11}] \quad (4)$$

$$O_H = [O_{H1,1}, \dots, O_{H1,18}, \dots, O_{H4,1}, \dots, O_{H4,11}] \quad (5)$$

$$O_t = [O_L, O_H] \quad (6)$$

Formula (4) is for longitudinal local optical flow vector O_L composed by the longitudinal optical flow of 72 sub regions, type (5) is for the transverse local optical flow vector O_H composed by transverse flow of 72 sub regions, in type (6), O_t is for the local optical flow vector.

By using the 2- norm to normalize O_t we can get the features expressed by radial histogram of local optical flow vector in current frame image I_t.

The Introduction of Recognition Method

There are many ways to solve the problem of statistical classification. This paper is mainly testing the identification ability of putting forward characteristics, so the most simple nearest neighbor classifier was chosen here[6]. The specific algorithm is as follows:

Firstly, the nearest neighbor of each frame in testing sequence ought to be found. Supposing that the feature vector of the t_{th} frame in testing sample sequences is M_Q^t, among which t=1, 2,… T, and the feature vector of the nth frame corresponding to the training sample is M_T^n. Then when using the Euclidean distance to test the similarity of M_Q^t and M_T^n, we can find that the training sample frame which keeps a minimum distance from M_Q^t is the nearest neighbor of the tth frame in testing sample sequence, as is shown in formula (7):

$$S_q=\min\|M_Q^t - M_T^n\|, \quad n=1, 2,...,N \quad (7)$$

Secondly, to assign the label of the action which is affiliated with the nearest neighbor training frame that is corresponding to the testing frame to the current testing frame, so that each frame in testing sequence will get an action label.

Finally, to do an action label statistic of each frame in the testing sequence, so that different testing sequence categories are classified, and each category is made of the actions which the same action labels are corresponding to. For example, there are 83 frames in diaria_bend sequence. Each frame is marked with the nearest action label, and the statistical results are [69,3,0,5,2,0,1,0,2,1], i.e. 69 frames are marked as No.1 action, 3 frames are marked as No.2 action, and so on. The largest number of votes is 69, and its action label is "1", the sequence will be identified as No.1 action.

Summary

This paper presents a human action recognition algorithm based on hybrid features. It combines the distance feature and contour flow characteristics of contour vector from contour centroid to the edge point, so as to get the mixed features to perform action recognition. From the recognition results of the third part, we can see that the mixed feature has been correctly identified 95% of the rate in Weizmann database and KTH database, fully demonstrating the effectiveness and feasibility of the algorithm.

Keyword: Diagnosis, Fuzzy set, Fault set, a sign set

Abstract: This paper discusses a diagnostic model based on the fuzzy relation equations in the diagnosis model, adding a time parameter, given the consistency between the fault symptom set and a set of observed signs of relevance, coverage, and equal quantitative indicators, these quantitative indicators can guarantee that the omission of a potential fault is neither in the case of incomplete knowledge, but also to get the best known symptom set matching solution. At the same time, diagnose problems in the knowledge of the adequacy and completeness of their relationships.

Introduction

Knowledge - based diagnosis of artificial intelligence branches. In practice , diagnose problems often related and time parameters , and diagnostic knowledge is often incomplete , reflected in two aspects : First , the observation of the signs of the system is not complete , for example , is limited by certain conditions , some the signs simply observe the less than or observation costly . Second, fault set and symptom set mapping relationship is not complete. How , in the case of incomplete knowledge , neither the omission of a potential failure , but also to get the best match solutions with existing observations , this paper investigates a stepwise refinement of diagnostic model , the model can be used with a deportation structure the various levels of the system .

Description of the problem

Diagnose problems p is defined as a seven- tupelo

$P = \langle\ D, M, R, M^+(\hat{D}, t+k), M^-(\hat{D}, t+k), M^+(t_0+i), M^-(t_0+i)\ \rangle$, among:

(1) $D = \{\ d_1, d_2 \cdots, d_q\ \}$ represents single - fault set of a given system, $A = \{\hat{D}_1, \hat{D}_2, \cdots, \hat{D}_p\ \}$ represents a set of failure modes of the system, then $D \subseteq A \subseteq \Gamma$, which Γ indicates the full combination of all single faults in the system. The base of the collection Γ and D is expressed as $|\Gamma|$ and $|D|$, respectively $|\Gamma| = 2^{|D|}$. Failure below represents the failure mode; failure set represents failure mode set.

(2) $M = \{m_1, m_2, \cdots, m_q\ \}$ represents a symptom set of a given system.

(3) $M^+(\hat{D}_j, t+k)$, $M^-(\hat{D}_j, t+k)$ $\hat{D}_j \in A$, $k = 0, \cdots, n$ respectively represents the sign sets that system inevitably appears and must not appear at the time of $t+k$ after system failure $\hat{D}_j$ at the time of t .

Definition 1: If $\forall \hat{D}_j \in A$, $k = 0, \cdots, n$ $M^+(\hat{D}_j, t+k) \bigcup M^-(\hat{D}_j, t+k) = M$, the system's diagnostic knowledge is sufficient. Otherwise, it is not sufficient.

If as $M^+(\hat{D}_j, t+k)$ and $M^-(\hat{D}_j, t+k)$ fuzzy subset, its membership functions are expressed as $\mu_{M^+(\hat{D}_j, t+k)}(m_f)$, $\mu_{M^-(\hat{D}_j, t+k)}(m_f)$. $\mu_{M^+(\hat{D}_j, t+k)}(m_f) = \mu_{M^-(\hat{D}_j, t+k)}(m_f) = 0$ represents nothing about the mapping relationship of $\hat{D}_j$ and m_f .

(4) $\mu_{t_0+i}(t+k)$, $k = 0, \cdots, n$ $i = 0, \cdots, m$ which indicates the degree of membership function or near at the time $t+k$ on the timeline moment t_0+i .

(5) $R \subseteq A \times M$ is the subset defined on the fuzzy relationship . The fuzzy set defined on $A \times M$, for each pair of $(\hat{D}_j, m_f)$, $\hat{D}_j \in A$, $m_f \in M$, $R(\hat{D}_j, m_f)$ is a set of $(\mu_{M^+(\hat{D}_j, t+k_1)}(m_f), t+k_1, \mu_{M^-(\hat{D}_j, t+k_2)}(m_f), t+k_2)$ .If $R_1 \subseteq D \times M$, apparently $R_1 \subseteq R$.

In fact, it is sufficient for a given system, the completion of the diagnostic problem solving knowledge does not need to be diagnosed. For either a failure mode, only require access to a subset of its symptom set premise is to ensure that the subsets of the signs can the corresponding failure modes and other failure modes to distinguish.

Definition 2:① in the accurate sets , $\forall \hat{D}_i, \forall \hat{D}_j \in A$, and $\hat{D}_i \neq \hat{D}_j$ so

$$DISCRIM(\hat{D}_i, \hat{D}_j) = \{ (M^+(\hat{D}_i, t+k) \cap M^-(\hat{D}_j, t+k)) \cup (M^-(\hat{D}_i, t+k) \cap M^+(\hat{D}_j, t+k)) \}$$

If $DISCRIM(\hat{D}_i, \hat{D}_j) \neq \varnothing$, the diagnostic knowledge of the system is complete.

②in the fuzzy sets, $\forall \hat{D}_i, \forall \hat{D}_j \in A$ and $\hat{D}_i \neq \hat{D}_j$

$$\mu_{DISCRIM(\hat{D}_i, \hat{D}_j)} = \max \{ \min(\mu_{M^+(\hat{D}_i, t+k)}(m_f), \mu_{M^-(\hat{D}_j, t+k)}(m_f)), \min(\mu_{M^-(\hat{D}_i, t+k)}(m_f), \mu_{M^+(\hat{D}_j, t+k)}(m_f)) \}$$

$\mu_{COMPLETE} = \min\{ \mu_{DISCRIM(\hat{D}_i, \hat{D}_j)} \}$, $\forall \hat{D}_i, \forall \hat{D}_j \in A$ and $\hat{D}_i \neq \hat{D}_j$ .When $\mu_{COMPLETE} > 0$, the system diagnostic knowledge is complete. In practice, given a threshold value, when $\mu_{COMPLETE}$ is greater than the threshold value, the diagnostic knowledge of the system is complete.

Proposition 1: If a system diagnostic knowledge is sufficient, the diagnostic knowledge of the system is complete. Otherwise may not be valid.

Proposition 2: If a system diagnostic knowledge is complete when the system fails, the diagnosis of the problem solving can be a unique interpretation.

3 Diagnostic models

3.1 Consistency diagnosis

Known $M^+(t_0 + i)$, $M^-(t_0 + i)$, $i = 0, \cdots, m$,consistent diagnostics is to find a fault set $\hat{D}_t$ .Any one of the failures of $\hat{D}_t$ is not contradictory with known symptom set, no contradiction in two aspects : First , the intersection between any failure of the corresponding necessarily occurred symptom set $M^+(\hat{D}_j, t+k)$, $k = 0, \cdots, n$ in $\hat{D}_t$ and known no signs of sets of $M^-(t_0 + i)$, $i = 0, \cdots, m$ is the empty set; The second, the intersection between the faults corresponding to the inevitable symptom set that does not appears $M^-(\hat{D}_j, t+k)$ $k = 0, \cdots, n$ and known to occur with the symptom set $M^+(t_0 + i)$, $i = 0, \cdots, m$ is the empty set, the precise collection represents as follows:

$$\hat{D}_{t_crisp} = \{ \hat{D}_j \subset A \quad \forall k = 0, \cdots, n \quad M^+(\hat{D}_j, t+k) \cap M^-(t_0 + i) = \varnothing \text{ and } M^-(\hat{D}_j, t+k) \cap M^+(t_0 + i) = \varnothing \} \tag{1}$$

For the accurate collection $F \cap G \neq \varnothing$ extending to fuzzy sets, the definition of an operator $cons(F, G) = \max(\min(\mu_F(u), \mu_G(u)))$

Definition 1: fuzzy subset $M^+(\hat{D}_j, t+k)$ and $M^-(t_0 + i)$ consistent degree of:

$$cons(M^+(\hat{D}_j, t+k), M^-(t_0 + i)) = \max (\min (\mu_{M^+(\hat{D}_j, t+k)}(m_j) * \mu_{t_0+i}(t+k) + \mu_{M^-(t_0+i)}(m_j))) \tag{2}$$

The degree of consistency of $M^+(\hat{D}_j, t+k)$ and $M^-(t_0+i)$ is higher, then the degree of inconsistency $\hat{D}_j$ and $M^-(t_0+i)$ is higher. Thus $cons(\ M^+(\hat{D}_j, t+k), M^-(t_0+i))$ is the degree of the conflict of $\hat{D}_j$ and $M^-(t_0+i)$.

Therefore, the degree of $M^+(\hat{D}_j, t+k) \bigcap M^-(t_0+i) = \varnothing$:

$$1 - cons(\ M^+(\hat{D}_j, t+k),\ \ M^-(t_0+i)) \tag{3}$$

Similarly, we can have the degree of $M^-(\hat{D}_j, t+k)$ and $M^+(t_0+i)$, $M^+(\hat{D}_j, t+k) \bigcap M^-(t_0+i) = \varnothing$. The membership function $\mu_{\hat{D}_t}(\hat{D}_j)$ of $\hat{D}_t$ is:

$$\begin{aligned}
\mu_{\hat{D}_t}(\hat{D}_j) &= \min(\ 1 - cons(\ M^+(\hat{D}_j, t+k),\ \ M^-(t_0+i)), \\
&\quad 1 - cons(\ M^-(\hat{D}_j, t+k), M^+(t_0+i))) \\
&= 1 - \max\ (cons(\ M^+(\hat{D}_j, t+k), M^-(t_0+i)), cons(\ M^-(\hat{D}_j, t+k), M^+(t_0+i))) \\
&= 1 - \max_{j=1,q} \max\ (\min\ (\mu_{M^+(\hat{D}_j, t+k)}(m_j) * \mu_{t_0+i}(t+k), \mu_{M^-(t_0+i)}(m_j)) \\
&\quad \min\ \ (\mu_{M^-(\hat{D}_j, t+k)}(m_j) * \mu_{t_0+i}(t+k), \mu_{M^+(t_0+i)}(m_j)))
\end{aligned} \tag{4}$$

For the known signs set $M^+(t_0+i)$ and no signs of sets $M^-(t_0+i)$, $\hat{D}_t$ includes all possible failure modes. If a failure mode $\mu_{\hat{D}_t}(\hat{D}_j) = 0$, you can rest assured that will give it up.

It should be noted here, because knowledge is not complete, some signs of the failure is not known, these failures and no known signs consistent diagnostic model, these failures are included in the explanation.

3.2 Diagnostic

Related diagnostic concern is the set of signs and known to occur , known to be no signs of failure, performance failure $\hat{D}_j$ occurs in the moment t, at the moment $t+k$ will inevitably be a sign of $M^+(\hat{D}_j, t+k)$ the moment t_0+i known symptom set $M^+(t_0+i)$ a certain degree of coverage, $\hat{D}_j$ necessarily does not occur at the timing $t+k$ the symptom set $M^-(\hat{D}_j, t+k)$ on a certain degree of time t_0+i is known not to occur symptom set $M^-(t_0+i)$ covering .

The precise collection is represented as:

$$\begin{aligned}
\hat{D}^*_{t_crisp} = \Big\{ & \hat{D}_j \in \hat{D}_{t-crisp}\ ,\ \ M^+(\hat{D}_j, t+k) \bigcap M^+(t_0+i) \neq \varnothing \\
& or \quad\ M^-(\hat{D}_j, t+k) \bigcap M^-(t_0+i) \neq \varnothing\ \Big\}
\end{aligned} \tag{5}$$

Extended to the fuzzy sets under expressed as:

$$\begin{aligned}
\mu_{\hat{D}^*_t}(\hat{D}_j) = \min(\mu_{\hat{D}_t}(\hat{D}_j),\ & \max(\ cons(\ M^+(\hat{D}_j, t+k),\ \ M^+(t_0+i)), \\
& cons(\ M^-(\hat{D}_j, t+k),\ \ M^-(t_0+i))))
\end{aligned} \tag{6}$$

3.3 coverage diagnosis

The accurate collection of the $\hat{D}^*_{t_crisp}$ further refinement can be obtained of the formula (7):

$$\begin{aligned}
\hat{D}^{**}_{t_crisp} = \Big\{ & \hat{D}_j \in \hat{D}^*_{t_crisp}\ ,\ \ M^+(t_0+i) \subseteq M^+(\hat{D}_j, t+k)\ \ or \\
& M^-(t_0+i) \subseteq M^-(\hat{D}_j, t+k)\ \ \exists k, \exists i, t+k = t_0+i,\ k = 0, \cdots, n \quad i = 0, \cdots, m\ \Big\}
\end{aligned} \tag{7}$$

Obviously there $\hat{D}^{**}_{t_crisp} \subseteq \hat{D}^*_{t_crisp}$,

E. Sanchez weak implication defined as

$$inc(F, G) = 1 \qquad \text{If}\ \ \mu_F \leq \mu_G \tag{8}$$

$$inc(F, G) = \mu_G \qquad \text{If}\ \ \mu_F > \mu_G \tag{9}$$

$$\text{For } k=0,\cdots,n \quad i=0,\cdots,m, \text{ if } \exists i, \exists m_f \in M^+(t_0+i),\ \exists k,$$
$$\mu_{M^+(t_0+i)}(m_f) \le \mu_{M^+(\hat{D}_j,t+k)}(m_f) * \mu_{t_0+i}(t+k),$$
$$\text{and } inc(\ M^+(t_0+i),\ M^+(\hat{D}_j,t+k)) = 1 \tag{10}$$

$$\text{For } k=0,\cdots,n \quad i=0,\cdots,m, \text{ if } \exists i, \exists m_f \in M^+(t_0+i),\ \exists k,$$
$$\mu_{M^+(t_0+i)}(m_f) > \mu_{M^+(\hat{D}_j,t+k)}(m_f) * \mu_{t_0+i}(t+k),$$
$$\text{And } inc(\ M^+(t_0+i),\ M^+(\hat{D},t+k)) = \mu_{M^+(\hat{D}_j,t+k)}(m_f) * \mu_{t_0+i}(t+k) \tag{11}$$

(10) Means that a sign belongs $M^+(t_0+i)$ the signs must belong to $M^+(\hat{D},t+k)$.This indicates that the coverage of the latter on the former, Therefore $\mu_{\hat{D}_t^{**}}(\hat{D})$=1. (11) Reflects the closeness of $\mu_{M^+(t_0+i)}(m_j)$ and $((\mu_{M^+(\hat{D},t+k)}(m_j),t+k)$.

Similarly defining $inc(\ M^-(t_0+i),\ M^-(\hat{D}_j,t+k))$.

In fuzzy sets:

$$\mu_{\hat{D}_t^{**}}(\hat{D}_j) = \min(\mu_{\hat{D}_t}(\hat{D}_j), inc(\ M^+(t_0+i),\ M^+(\hat{D}_j,t+k)),$$
$$inc(\ M^-(t_0+i),\ M^-(\hat{D}_j,t+k))) \tag{12}$$

3.4 Equality diagnostic

$$\text{In accurate collection, } \hat{D}_{t_crisp}^{***} = \{\hat{D}_j \in \hat{D}_{t_crisp}^{**},\ M^+(t_0+i) = M^+(\hat{D}_j,t+k) \ \ and$$
$$M^-(t_0+i) = M^-(\hat{D}_j,t+k) \ \ \exists k, \exists i, t+k=t_0+i,\ k=0,\cdots,n \quad i=0,\cdots,m \ \}$$

In fuzzy collection,

$$\mu_{\hat{D}_t^{***}}(\hat{D}_j) = 1 \quad \text{if } \min(\mu_{M^+(t_0+i)}(m_f), \mu_{M^+(\hat{D}_j,t+k)}(m_f) * \mu_{t_0+i}(t+k)) \ne 0 \ \ and$$
$$\min(\mu_{M^-(t_0+i)}(m_f), \mu_{M^-(\hat{D}_j,t+k)}(m_f) * \mu_{t_0+i}(t+k)) \ne 0 \tag{13}$$

4 Conclusions

This paper presents the stepwise refinement of diagnostic model to ensure that the omission of a potential failure, but also in the case of incomplete knowledge neither the solution with the best known symptom set match. Complexity of diagnostic problem solving, and to overcome the high price probability calculation based on the fuzzy relation equations, the model can be used to meet the real-time requirements. Text definition of 1 , 2 and Proposition 1,2 diagnose the problem solving knowledge completeness criterion also makes access to knowledge work with clear objectives , and avoid expending energy to get those redundant knowledge .

Keywords: pulley；straightening machine；automatic correction；motion simulation based on Pro/E

Abstract. Pro/Engineer(Pro/E) was applied to design a new kind of motorcycle belt pulley straightening machine, which was composed of electric cylinder and stepper motor in this paper. The effect of positioning and correcting were achieved by the straightening machine during operation. The motion simulation for correcting key parts was done under mechanical module of the software. The mechanism motion speed and the motion trails of the straightening machine were acquired under different positioning accuracy. Through analysis on the motion trails, the best range of the correcting parts′ rotational speed can be optimized.

Introduction

When a motor pulley has a deformation and bending and so on, it can affect the normal operation of the internal drive motorcycle. Even worse it will generate serious personal injury and property loss to motorcycle users. Existing motor pulley correction methods mostly make use of heavy manual equipment to correct, and the efficiency and accuracy of the correction methods are low. The common correction devices are roller plate straightening machine in sheet metal processing industry. The correction devices can automatically correct sheet, but it cannot be applied to the correction of a camber motorcycle pulley. In order to improve the correction efficiency and accuracy to the motor pulley, this paper designed a new type pulley straightening machine，which can greatly improve the low efficiency and low accuracy of the motor pulley[1].

Pro/E Software Introduction

Pro/Engineer is called for Pro/E, it has more powerful functions in product structure design and parametric modeling. Pro/E is the system adopt the entity modeling based on characteristics, it can random drawing and change the model parameters by means of parameter design. The Phenomenon any changes of the whole design project can reflected in the related links of the whole process of design can come true by Pro/E taking advantage of the unity of grassroots database. What's more, all modules of Pro/E are interconnected, for example, if a place be modified in the process of product development, Then the whole design content including engineering documents will automatically change. In the process design products by Pro/E, users can use familiar characteristics as the components of the product model, leading to the product design becoming easy. In terms of mechanical structure simulation, Pro/E is easy to find potential assembly conflicts and defects, and feedback the related information to the designer in time. Relatively speaking, Pro/E give a poor performance in surface modeling[2−3].

Straightening machine structure design

The main composition and working principle of structure. In this paper, when the motorcycle pulley straightening machine is working, the cylinder movement will fix the pulley on the fixed axis of the workbench. Following fixed pulley, the stepper motor drive the pulley rotating. When the motor drive the pulley rotating, the eddy current sensor collect data distance data, system set 5˚as a set of distance data, rotating a ring collect 72 sets of distance data used for detecting the deflection of the pulley. The distance data the eddy current sensor collected transfer to the single-chip microcomputer system, the position the highest point on the surface of the pulley can be calculated and located. The peak of the surface of the pulley can be located in underneath of the electric

cylinder head by controlling the stepper motor drive belt rotating. According to the difference of the highest point and the lowest point of the pulley measured by the device, the electric cylinder axis press, electric cylinder and the squeeze head can stamping pulley. If this operation has been completed, the above process repeat until the data measured up to the requirement of the pulley surface flatness[4].

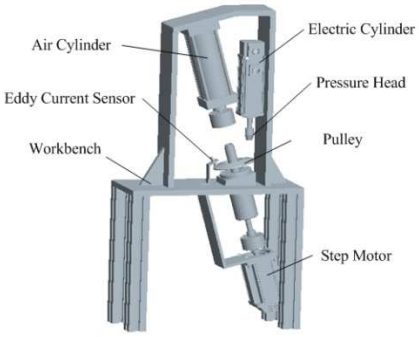

Fig.1 Pulley straightening machine structure chart

Selection and design of the key components. In the process of straightening machine working, the work on, the pulley can be fixed by the fixed shaft and the cylinder head, which on the worktable. In the process of eddy current sensor detecting surface deformation of the pulley, the stepper motor drive the pulley to rotate. When the electric cylinder and the squeeze head stamping to the peak of pulley, the position of the pulley is fixed. As a result, the rotation of the pulley is stop. Hence, it is necessary to design the cylinder head. In this paper, the cylinder head was used to fix pulley, which constitute a pair of tapered roller bearing, matching cups and bearing cower.

To improve the correction efficiency of the pulley for looms, the way of electric stepper motor can be corrected rapidly by shorting the cylinder's and electric cylinder's stroke and improving the speed of the cylinder, the cylinder and electric stepper motor. Comprehensive consideration the energy consumption of the straightening machine and pulley correction effect and the running speed of cylinder, electric cylinder and stepping motor can be controlled in a proper range. Eventually, the correction effect of the pulley for looms at different speeds is simulated by the Pro/E mechanism motion simulation module, which has obtained the best corrective running speed of the pulley for looms under that simulation.

Motion simulation analysis

Motion Simulation Setting. When the simulation is proceed by Pro/E，it can achieve the final assembly by setting various constraints, which consists of rigid constraints and user-defined constraints. Rigid constraint mainly aimed at the rigid assembly of fixed fittings. The assemblies ultimately are required limited at six degrees of freedom[5], the choose of assembly connection mode for rigid constraints including matching, insert and alignment, etc. User-defined constraints mainly aim at the assembly of the component, requesting guarantee freedom of moving parts is greater than 1 or equal to 1.What's more, the freedom constraint assembly connection mode including pin connection, sliding connection and slot connection and so on for the user to choose. The paper establishes the 3 d mode of motorcycle pulley straightening machine by Pro/E, setting the connection between the electric cylinder shaft and electric cylinder, the cylinder shaft and cylinder as sliding connection, setting the connection between the cylinder and the cylinder shaft, the fixed axis and the bearing as the pin connection, the rest constraints between the components and the workbench are rigid constraint.

When the assembly straightening machine model is input to the Pro/E motion simulation mechanism to simulate, three servo motor parameters is need to be defined on the basis of the actual work movement of the straightening machine[6]. According to the distance (L = 80 mm) between

the surface of the squeeze head and the pulley corrected, the speed of electric cylinder is set to 80*(t-2) mm/s, including 2s≤t≤3s. According to the movement condition of the cylinder and cylinder axis, the motor is set as slide servo motor, and the speed is set to t*75mm/s, including 0s≤t≤1s. According to the actual situation of step motor, the motor is set as rotary motor, and the speed is set to 360*(t-1)deg/s, including 1s≤t≤2s.When servo motor parameter setting is completed, mechanism analysis option need to be selected at the machinery analysis interface, which set a series of motion simulation operation parameters, including the begin time ,the end time, the total frame number and the time per frame. This paper set the begin time to 0s and set the end time to 10s, and set the rest parameters as the default parameters.Specific straightening machine motion simulation parameters setting as shown in table 1.

Table.1 Motion simulation parameters settings table

simulation mechanism	parameters of velocity	time parameters
electric cylinder	80*(t-2)mm/s	2s≤t≤3s
air cylinder	t*75mm/s	0s≤t≤1s
Stepper motor	360*(t-1)deg/s	1s≤t≤2s

The simulation result and analysis. After setting the parameters of corrective machine movement simulation, the mechanism motion simulation analysis can start. At the same time, the straightening machine model can simulate the actual corrective motion of the belt pulley. After the simulation enter the playback interface, the simulation results also can be watched from different angles, and the dynamics characters of straightening machine can be shown. In the process of motion playback, the working parts movement can be analyzed, which detect he interference phenomenon. The interference areas can be automatically highlighted and stop play when the interference phenomenon is detected. Now the interference part is changes until all the motion have no interference, which achieving the expected requirements. An example of the squeeze head, the position, the velocity and the acceleration curve are shown in figure 2 according the setting parameters of the electric cylinder servo motor[7].

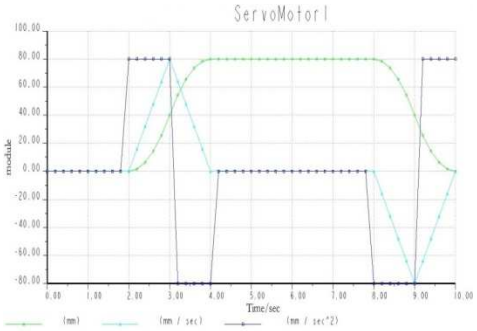

Fig.2 The simulation curve of the position of squeeze head, the velocity and the acceleration

From figure 2, press and return time of the squeeze head under the set speed is 2s.At the begin time and the end work time, the maximum acceleration of the squeeze head can reach ± 8 0mm/s2. But the numerical value is sudden change, which will have a certain impact on motive mechanisms. Considering the squeeze head's quality is small, the impact force will not affect the actual operation of the straightening machine.

Summary

In order to improve the motor pulley correction efficiency and quality of correction, this paper designs a new type pulley straightening machine based on Pro/E. Simulating the motion of the whole structure by mechanism simulation module of Pro/E, it can effectively discover design flaws and quickly achieve equipment operation and assembly requirements. And simulating the motion of

the component by mechanism simulation module of Pro/E, it can easily obtain running speed and acceleration. Above simulation data optimize the operation parameters of the electric cylinder and the stepping motor and other parts, providing reference data for confirming the final operation parameters of straightening machine.

Keywords: The spray pump; Crankshaft; Soildworks; Simulation analysis

Abstract. For the research of the mine large displacement spray pump in structure characteristics, each part of the spray pump should make use of Solidworks 3 d modeling, then assembled to be assembly at the same time. During the process of assemble, the assembly must be checked for interference. And simulate the spray pump motion, operation parameters are obtained according to the basic parameters and theoretical analysis. It's of great significance to enhance the efficiency of the practical production in coal mine by bearing the main stress, testing and optimizing the performance of the crankshaft.

Introduction

With the rapid development of China's coal industry, there are higher and higher demands are proposed for the safety and the efficiency of fully mechanized equipment in coal reliability. The spray pump is the key equipment that high pressure spray pump station provides the required pressure water of spray system for large and medium-sized coal winning machine and heading machine. Whether its design is reasonable or not directly decides the safety and reliability of coal winning machine and heading machine during the working. With the constant progress of science and technology, spray pump are in a gradual increase in nominal flow rate and pressure, spray pump types are also increasing, in order to adapt to the working characteristic of various types of mining machinery. This makes the development and research that meet the requirements of the use of new emulsion pump has become the top priority in our country. In order to shorten the development cycle and reduce development costs, the use of Solidworks modeling and simulation analysis of course to be an ideal choice[4].

The main structure and working principle of the spray pump

Spray pump is a kind of device which can change mechanical energy of the motor's into the hydraulic energy of working medium. In the coal mine industry, spray pump are used mainly with spray pump body, explosion-proof motor, coupling, hydraulic system and the base together in working[2]. High pressure spray pump used in mine mainly relies on the power offered by the electrical machine, letting the rotation of the crankshaft movement into the straight line reciprocating movement of the spray pump column to realize the liquid of suction and ejection. The spray pump adopts horizontal three plunger structure which can shape increasing the nominal flow volume under the condition of guaranteed in minimize spray pump. Spray pump mainly include housing, crankshaft, connecting rod, connecting rod and the bush, etc[1,3]. Above all, the carrying capacity of crankshaft and connecting rod is the key to the normal operation of the spray pump as it is the main transmission part. The concrete structure diagram is shown in figure 1.

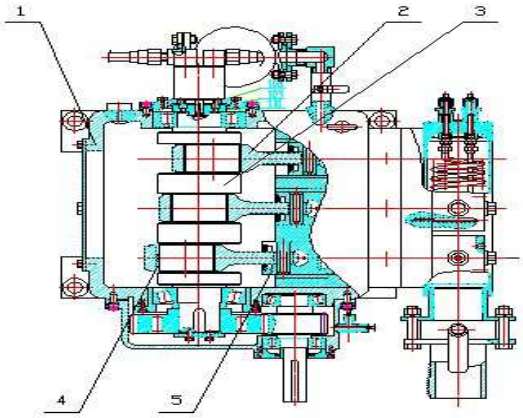

Fig. 1 Structure diagram of the new spray pump
1. The enclosure 2. Connecting rod 3.The crankshaft 4. Transport mechanism
5. The bush 6. The slider

Make use of Solidworks 3 d to model all the parts of the spray pump

Establishing the modeling of the spray pump modeling is the precondition of simulation analysis. In various parts of the spray pump, the crankshaft is the one of the core component. Its modeling is quite complicated. Now, in the case of the crankshaft, briefly describes the modeling process: first of all draw the outline of the crank on the sketch, stretching it into the crank entity, then use tensile entity command to create crank shaft neck. Similar to the above steps, gradually achieve the whole modeling of crankshaft. We can also finish other parts modeling of spray pump with the appropriate command[5].

The achievement of virtual assembly

Virtual assembly is to design and product 3 d model for preassembly by using the virtual technology in virtual environment. Solidworks virtual assembly modeling provides three effective way of assembly, including the top-down, bottom-up and more than the combination of the two ways. You can put the parts together as required just by a few simple steps. This paper chooses the assembly design approach which general engineering habit of top-down.

All the parts are assembled transfer into according to the reasonable when assembling and ordering. The part called first is often fixed default, then the others assembly parts are assembled with the requirements of assembly. The spray pump assembly model is shown in figure 2.

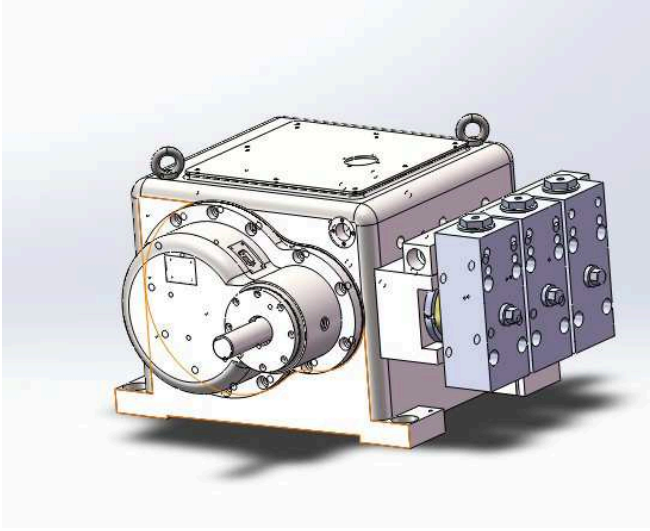

Fig. 2 The spray pump assembly model

After completion of assembly, interference check is needed. Several interference parts must be modified to be eliminated, some can be ignored completely, such as interference between threads and the bolts.

Based on the simulation analysis

SolidWorks simulation, not only can be used to simulate the mechanical movement of assembly and they produce force, but also can determine the related factors, such as the interference between parts, each parts pressure and energy consumption, etc. The designer can simulate the different motion state according to the given conditions and parameters of the product and inspection motion performance the correctness of the design and calculation[6]. At the same time can also determine the scheme of break time, failure time, parts and whether there is potential safety hazard or not, etc. The mechanical simplify are needed before the analysis, otherwise it is hard to calculate, even if the results are wrong. Therefore those which do not affect the results of the analysis of parts must be compressed or deleted. Simplified model is shown in figure 3.

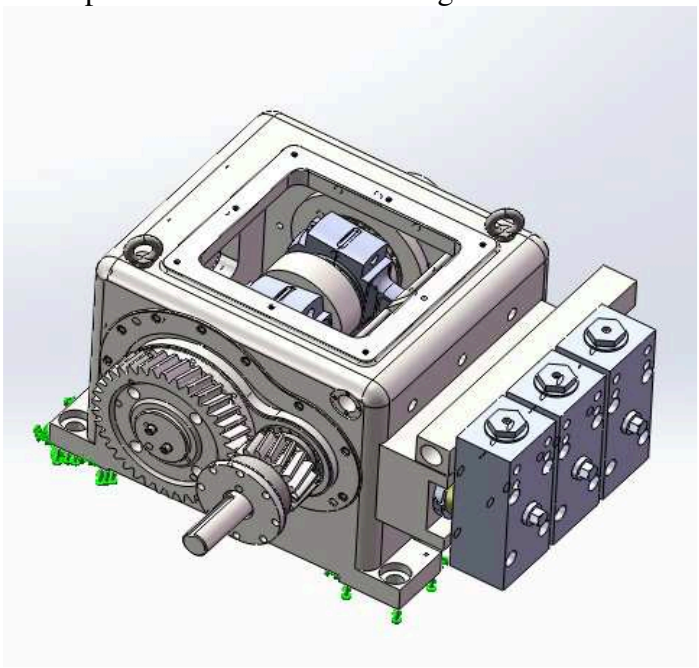

Fig. 3 The simplified assembly modeling

Set the parameters

Select material. The crankshaft as the main components of the spray pump, it choose 42CrMoA alloy steel in material;

Generate the static analysis example. Select the crankshaft initial state by generating the static analysis example;

Apply the fixed constraint and load pressure. Select power is 280 KW, rotational speed is 1480r / min motor as power source, so the input torque of 1806756 n, mm; Plunger cross section by the resistance of the emulsion, through the connecting rod is passed to the crankshaft. Each plug column resistance by about 2000 n through calculation;

Mesh. The parts mainly selecting the crankshaft as the grid, and grid for crankshaft by setting grid options;

Run the example. By running the example, the crankshaft stress, displacement and strain diagram can be received;

Evaluate the safety of the design. Through analysis of the force in maximize known crank of crankshaft stress, the dangerous section can be found, and then determine whether the design is reasonable or not.

Conclusion

(1) Through the simulation analysis of crankshaft, the data and the design value can be compared, then verify the validity of the design and calculation results, at the same time the deficiencies and defects in the design can be improved, which can make a design become more reasonable

(2) Which using the Solidworks 3 d modeling and simulation analysis are carried out on the products can improves the design efficiency and accuracy greatly, and also proposes more reliable and comprehensive analysis in product long life of the service and high reliability. Above all, it can be certainly seen that this method has practical application in production.

Keywords: PDC, Anchor bit, Tooth rake angle

Abstract. PDC anchor bit has the very good rock fragmentation abilities with high penetration rate and long drilling time,which makes the drilling efficiency highly improved and the economic benefit remarkably increased.Now PDC anchor bit has been widely used in drilling field.But for the reason that it is sensitive to the formation characteristics and working conditions,it doesn't achieve good performance in homogeneous formations such as conglomerate and interbeded sections.In order to reach the goal of enlarging the scope of PDC anchor bit application in oilfields,it is necessary to study the breakage mechanism in conglomerate formations and design the PDC anchor bit optimally.

Introduction

Drilling efficiency is the value of PDC anchor bit in the first study, this chapter through the establishment of the statics model of stress of the PDC anchor bit and drilling process chip fluid simulation model to study each bit geometric parameters of tooth rake angle α influence on the stress distribution.

Bit stress under different surrounding rock deformation

PDC anchor bit of finite element analysis combined with surrounding rock stress, in full consideration the factors that influence the PDC anchor bit stress change and the computer can spit out results, so the selection of PDC anchor bit F in the propulsion force and its speed v as the independent variable, the remaining factors as constants to simplify the mechanical model. PDC anchor bit by axial propulsive force F is provided by drill, drill the rated power of P unchanged, as a constant value. Bit by N increased with the increase of rotational speed to reduce torque and drilling mudstones high drilling time, drilling drilling time is low, therefore, by analyzing the change of the speed v to force under different surrounding rock stress, namely

$$P = dN \cdot v = const$$

When PDC anchor bit drilling litho logy according to the particle size and rotation of drilling obstructive divided into sandstone, sandy mudstone and shale, the corresponding stress changes following chart:

1. The mudstone of PDC anchor bit speed is about 750 rad/min

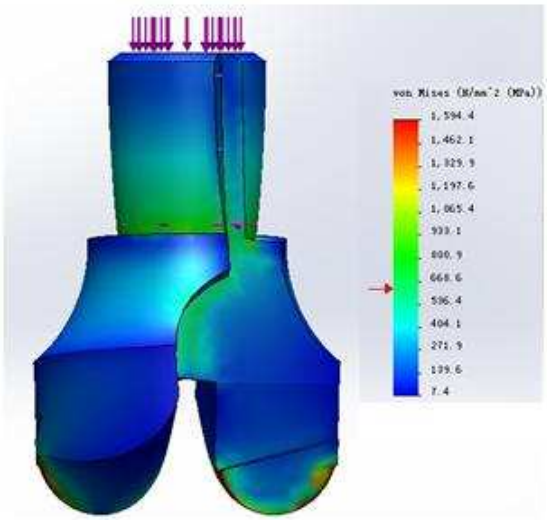

Fig. 1 Mudstone in bit stress nephogram

2. The shaly sand of PDC anchor bit speed is about 1100 rad/min

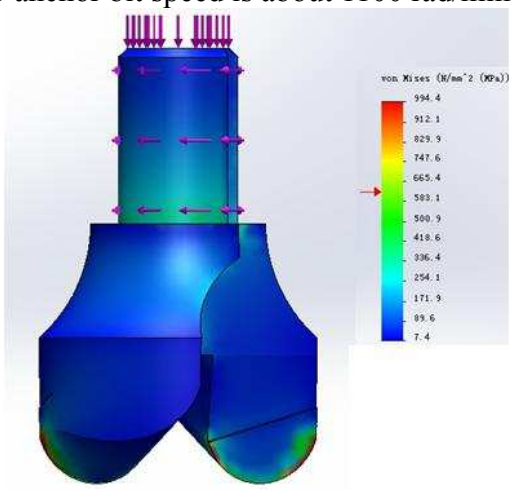

Fig. 2 Shaly sand in the bit stress nephogram

3. The sandstone of PDC anchor bit speed is about 1500 rad/min

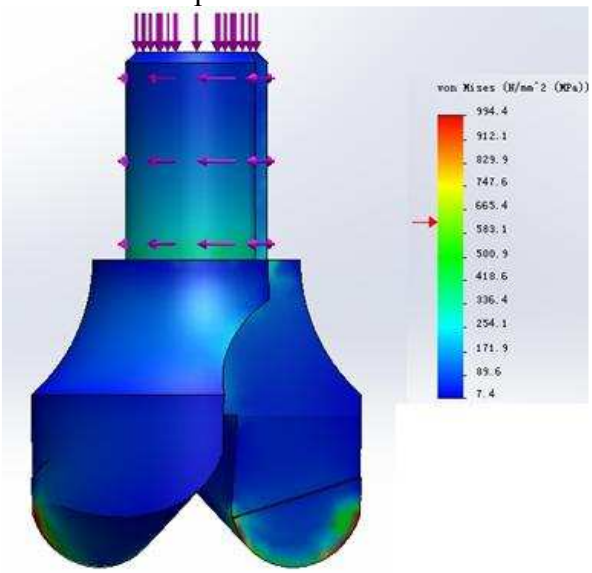

Fig. 3 Sandstone drilling stress nephogram

Under different litho logy of numerical statistics, tooth Angle alpha before the change on the dangerous point of maximum stress can be classified as the chart below:

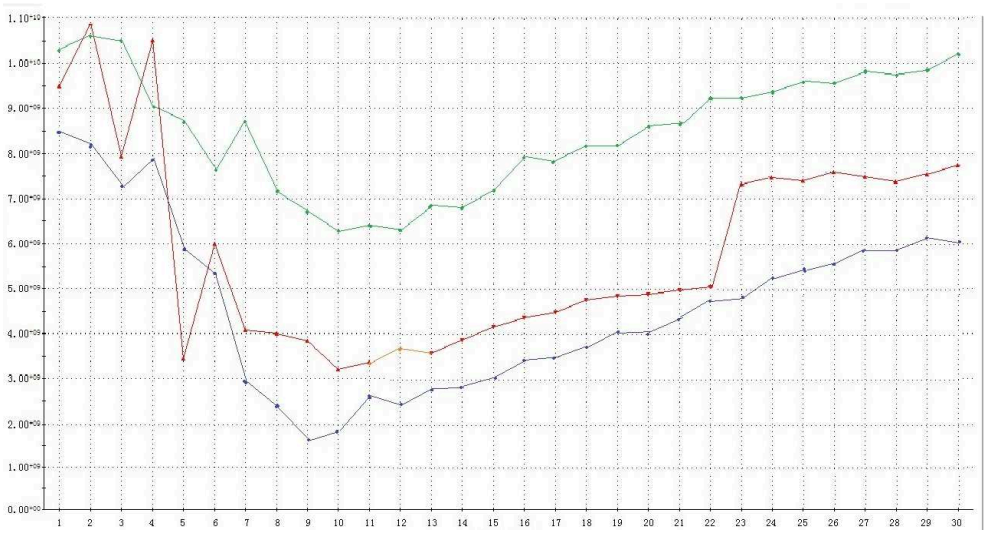

Fig. 4 The effects of the stress with tooth rake angle changing on

For PDC anchor bit, the accuracy of 1 degree is so large, but the actual calculations capability of the computer has to be considered. The way of superimposing two operations can improve the accuracy of tooth rake angle.

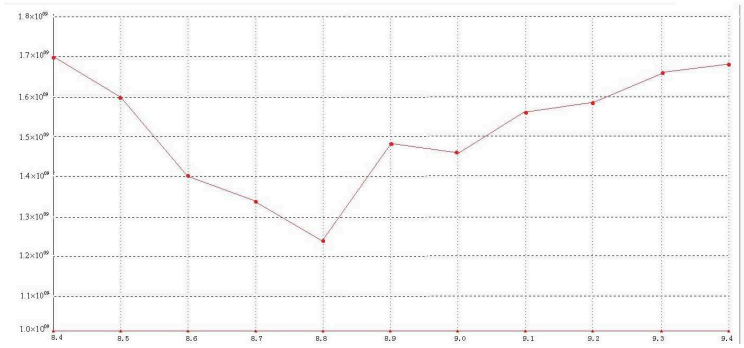

Fig. 5 The stress variation of tooth rake angle in mudstone

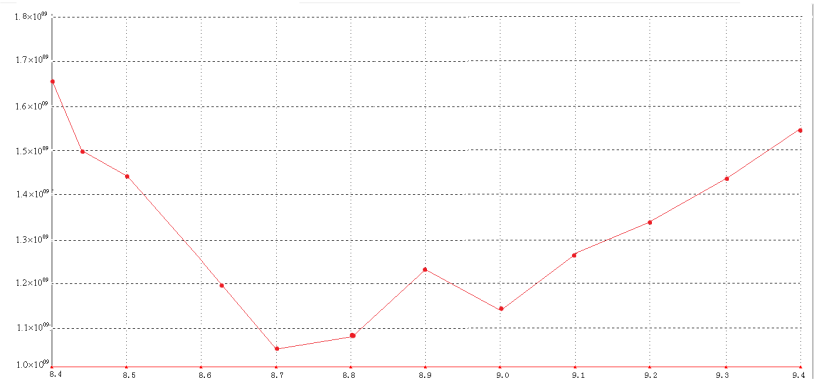

Fig. 6 The stress variation of tooth rake angle in shaly sand

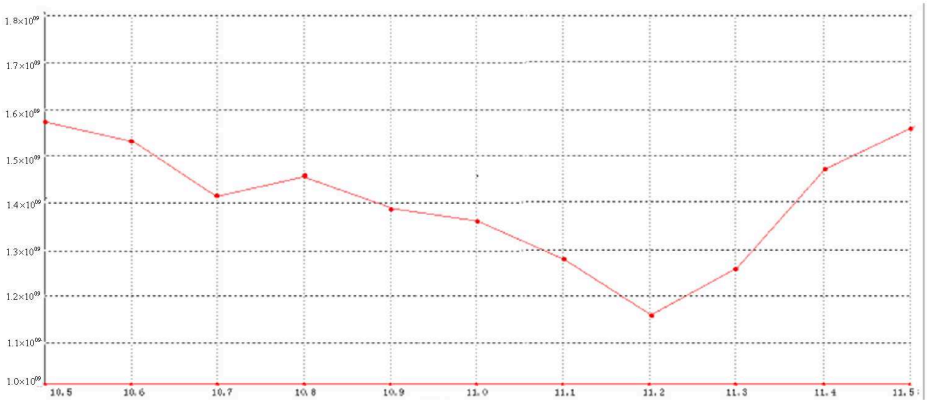

Fig. 7 The stress variation of tooth rake angle in sandstone

Conclusion

Established the statics model of PDC anchor bit, its stress and torque are simulated, and the geometric parameters of PDC anchor bit are classified and studied the Angle change on the tooth Angle alpha before the change of the maximum stress, contact the actual situation, under different surrounding rock is divided into sandstone, mudstone and argillaceous sandstone several ways to discuss, and try to under the condition of without increasing computer computation, two numerical simulation, in order to improve the calculated tooth Angle alpha before the best accuracy.

Keywords: Planetary train; Herringbone; Tooth profile parameter; strength safety coefficient

Abstract. The influence of tooth profile parameters on the strength safety coefficient can provides the basis for the design of high strength herringbone planetary train system. Through calculation of the three strength safety coefficients (contact strength, bending strength, bonding strength), curves of the relationships between the tooth shape parameters (addendum coefficient, tip clearance coefficient, spiral angle) and the strength safety coefficients have been obtained and the impact of tooth shape parameters on the three strength safety coefficients have been analyzed. The research results show that the bigger addendum coefficient can be selected for the design of high strength herringbone planetary train system. In order to satisfy bending strength, no-undercut and lubrication condition the smaller tip clearance coefficient should be taken. The strength safety coefficients are bigger with the increase of spiral angle, so a bigger spiral angle may be appropriately chosen.

Introduction

Herringbone has the advantages of strong bearing capacity, stable transmission, small vibration and noise etc. The herringbone planetary train system is widely used in the heavy mechanical train system of high speed and heavy load.

The strength safety coefficient of high speed and heavy load herringbone planetary train system is bigger. Variation of tooth profile parameter can change the strength safety coefficient. The influence of tooth profile parameters on the strength safety coefficient can provides the basis for the design of herringbone planetary train system. Domestic and foreign scholars on the impact of tooth profile parameters on the strength safety coefficients of the gear transmission system which conduct some theoretical and experimental research. Abroad, Doctor of Engineering Namigasenshou [1] researched in the influence of various important parameters of gear for surface contact strength, bending strength, bonding strength; Andrzej etc [2] by ISO and AGMA standard gear load is applied, come to different tooth profile parameters corresponding curves of root strength. China, Jinglong Hung etc [3] using the Hertz contact theory, analysis of impact of the tooth pressure angle on contact strength, the tooth strength with the variation regularity of pressure angle is obtained; Dongan Zhan etc [4] analyzes the influencing factors of helical gear spiral angle size and ranges in high speed gear transmission; Ying Wang etc [5] inspect impact of addendum coefficient, pressure angle, spiral angle, gear ratio and the modification coefficient on gear performance. These studies mainly on a single or a pair of meshing gears, but for the whole of herringbone planetary train system aspects little studied.

In this paper, by changing of the tooth profile parameters(addendum coefficient, tip clearance coefficient, spiral angle), calculation of strength safety coefficients, curves of the relationships between the tooth shape parameters and the strength safety coefficients have been obtained, and the impact regularity of tooth profile parameters on the strength safety coefficients have been analyzed.

Three strength safety coefficients

The strength safety coefficient of the gear transmission system including the contact strength safety coefficient, bending strength safety coefficient, scuffing load capacity safety coefficient.

Contact strength safety coefficient S_H expressed as:

$$S_H = \frac{\sigma_{H\lim} z_N}{\sigma_{HO}} \cdot \frac{z_L z_v z_R z_w z_x}{\sqrt{K_A K_v K_{H\beta} K_{H\alpha}}} \tag{1}$$

Bending strength safety coefficient S_F expressed as:

$$S_F = \frac{\sigma_{F\lim} y_{ST} y_{NT}}{\sigma_{FO}} \cdot \frac{y_{\sigma relT} y_{RrelT} y_x}{K_A K_v K_{F\beta} K_{F\alpha}} \tag{2}$$

Scuffing load capacity safety coefficient S_B expressed as:

$$S_B = \frac{\vartheta_{S\text{int}}}{\vartheta_{\text{int}}} \tag{3}$$

Eq. (1), (2) in symbol meaning see references [6], Eq. (3) in symbol meaning see references [7].

In the planetary gear transmission system, the gear contact strength safety coefficient including contact strength safety coefficient of sun gear, planetary gear and internal gear; the gear bending strength safety coefficient including bending strength safety coefficient of sun gear, planetary gear and internal gear; the gear scuffing load capacity safety coefficient including bonding strength safety coefficient of sun gear and planetary gear, bonding strength safety coefficient of planetary gear and internal gear.

Impact of tooth profile parameters on the strength safety coefficient. Herringbone planetary train system diagram see reference [8]， the main parameters of herringbone planetary train system: input power 85.5*kw*, spindle speed 6500*r/min*, life expectancy 24000*h*, transmission ratio 6.3, the number of planetary gear 3. Parameters of the gear transmission system shown in table 1.

Table 1 Parameters of the gear transmission system

parameter	value
modulus(mm)	4
sun gear teeth	19
planetary gear teeth	41
internal gear teeth	101
sun gear modification coefficient	0.229
planetary gear modification coefficient	-0.182
internal gear modification coefficient	-0.135
spiral angle(°)	24.399
tooth width coefficient	0.710

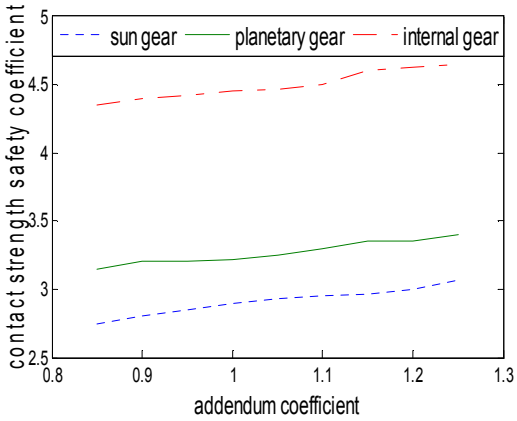

Fig.1 The addendum coefficient effect on the safety coefficient of contact strength

In this paper tooth profile parameters include the addendum coefficient h_a^*, tip clearance coefficient c^* and spiral angle β are studied. Due to the change of pressure angle α value, the actual center distance between sun gear and planetary gear and between planetary gear and internal gear will be changed, they may not equal, that does not meet the concentric condition, so do not

make the pressure angle α analysis of herringbone planetary train system strength safety coefficient impacts.

Impact of addendum coefficient on three strength safety coefficients. The other parameters unchanged, the three strength safety coefficients with addendum coefficients curve shown in figure 1 to figure 3. Figure 1, Figure 2 shows that contact strength and bending strength safety coefficient of sun gear, planetary gear and internal gear are bigger with the increase of the addendum coefficient. Figure 3 shows that scuffing load capacity safety coefficient has a decreasing trend with increases of the addendum coefficient, but not obvious.

Increase the contact ratio of gear transmission, to improve bearing capacity of gear transmission has important significance [9]. The contact ratio is bigger with the increase of addendum coefficient. Increase the addendum coefficient can improve the gear contact strength and bending strength. From figure 1, figure 2 and figure 3：The bigger addendum coefficient can be selected for the design of high strength herringbone planetary train system.

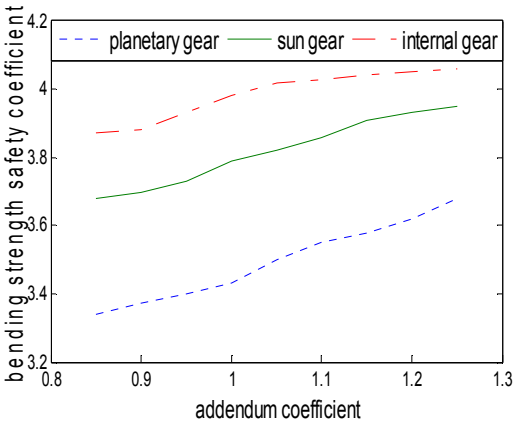

Fig.2 The addendum coefficient effect on the safety coefficient of bending strength

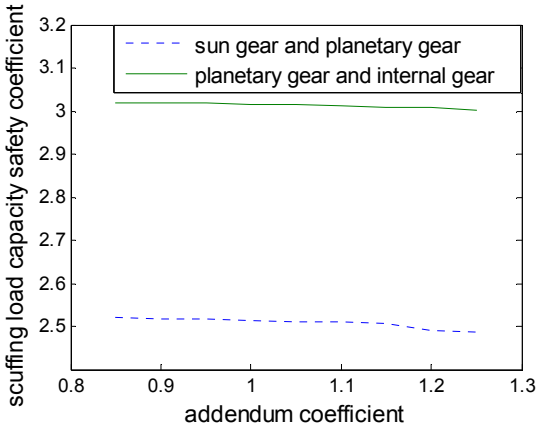

Fig.3 The addendum coefficient effect on the safety coefficient of scuffing load capacity

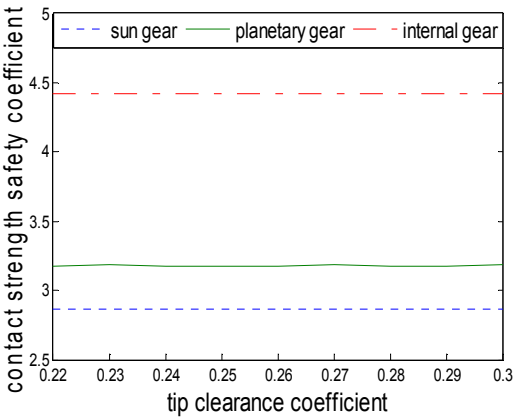

Fig.4 The tip clearance coefficient effect on the safety coefficient of contact strength

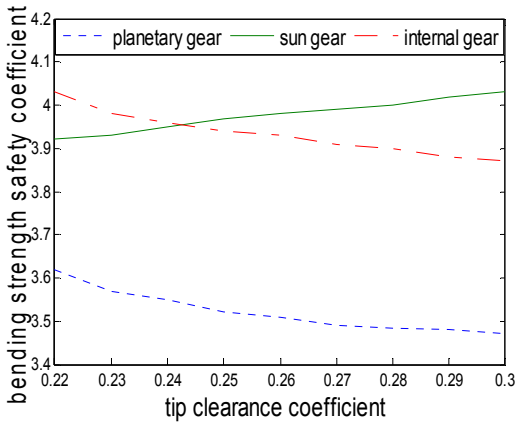

Fig.5 The tip clearance coefficient effect on the safety coefficient of bending strength

Impact of tip clearance coefficient on three strength safety coefficients. The other parameters unchanged, the three strength safety coefficients with tip clearance coefficient curve shown in figure 4 to figure 6 .Figure 4, Figure 6 shows that contact strength and scuffing load capacity safety coefficient of sun gear, planetary gear and internal gear altered little when the tip clearance coefficient increased. Contact strength and scuffing load capacity was mainly affected by the parameters of the tooth surface, so the tip clearance coefficient little effect on contact strength and scuffing load capacity.

Figure 2 show that contact strength safety coefficient of sun gear, planetary gear and internal gear are smaller with the increase of the tip clearance coefficient. Tip clearance coefficient increases,

single arm gear increases，reduced bending strength of the gear. For the design of high strength herringbone planetary train system，no-undercut and lubrication condition the smaller tip clearance coefficient should be taken.

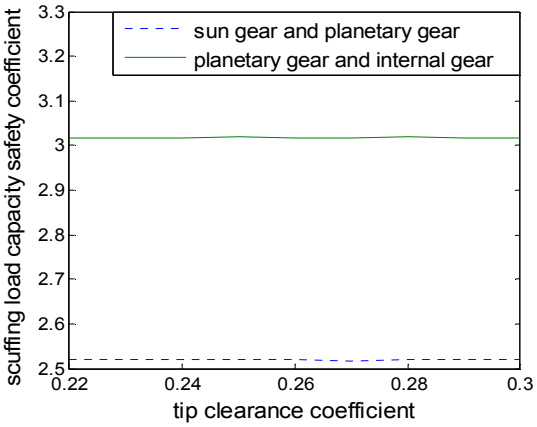

Fig.6 The tip clearance coefficient effect on the safety coefficient of scuffing load capacity

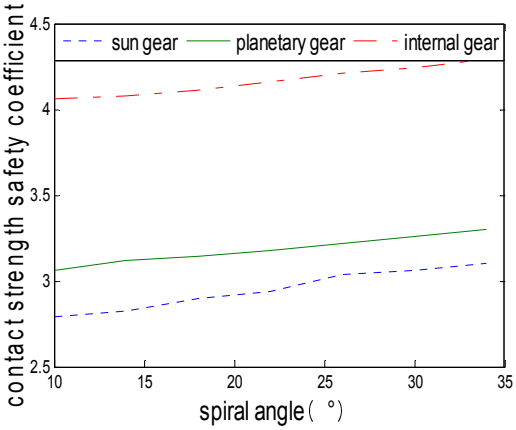

Fig.7 The spiral angle effect on the safety coefficient of contact strength

Impact of spiral angle on three strength safety coefficients . The other parameters unchanged, the three strength safety coefficients with spiral angle curve shown in figure 7 to figure 9. Visible, with the increases of spiral angle, three strength safety coefficients increase.

The contact ratio of herringbone is bigger with the increase of spiral angle [9]. Contact ratio increases and the number of meshing teeth increased. Single tooth to withstand the load becomes smaller, bearing capacity is stronger also. Scuffing damage not easy to be caused when single tooth to withstand the load becomes smaller .Increasing the spiral angle can improve the three strength safety coefficients.

Helical gear spiral angle is usually taken $\beta = 8^\circ \sim 15^\circ$, herringbone axial forces offset each other, β value up to 30°or more [1]. The bigger spiral angle can be selected for the design of high strength herringbone planetary train system under conditions permit.

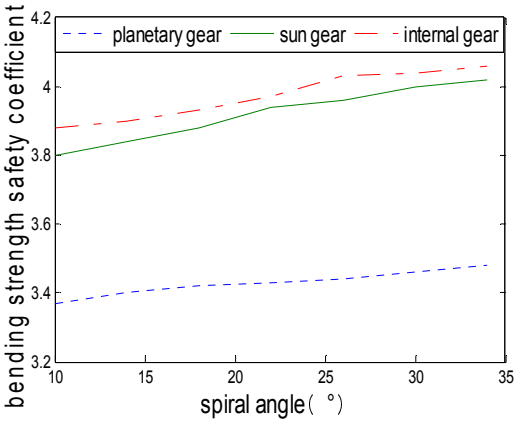

Fig.8 The spiral angle effect on the safety coefficient of bending strength

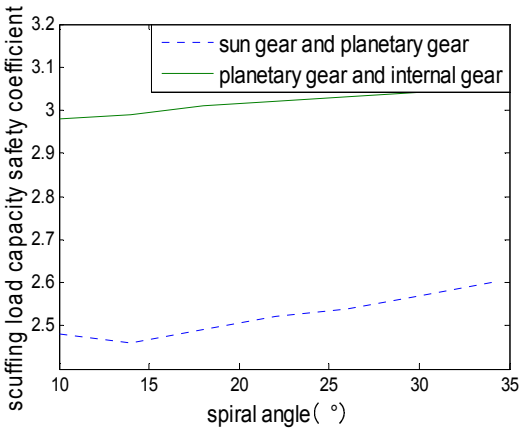

Fig.9 The spiral angle effect on the safety coefficient of scuffing load capacity

Conclusions

(1) Contact strength and bending strength safety coefficient of sun gear, planetary gear and internal gear are bigger with the increase of the addendum coefficient, the addendum coefficient little effect on safety coefficient of scuffing load capacity. The bigger addendum coefficient can be selected for the design of high strength herringbone planetary train system.

(2) Contact strength and scuffing load capacity was mainly affected by the parameters of the tooth surface, so the tip clearance coefficient little effect on contact strength and scuffing load capacity. Tip clearance coefficient increases, single arm gear increases，reduced bending strength of the gear. To meet no-undercut and lubrication condition the smaller tip clearance coefficient should be taken.

(3) The contact ratio of herringbone are bigger with the increase of spiral angle. Contact ratio is bigger，bearing capacity is stronger also，and scuffing damage not easy to be caused. Appropriate increase spiral angle can improve three strength safety coefficients.

Keyword: Hydraulic support, LabVIEW, Pressure monitoring

Abstract: Hydraulic support is widely used under the mine while the pressure is the most important factors of its safety.In view of the defects about present pressure monitor of mining hydraulic support ,designing a mining hydraulic support pressure monitoring system based on LabVIEW.This article mainly introducing the overall structure of the system, hydraulic system principle, the LabVIEW program, data communication and interface design.Using LabVIEW collection and storage support's real-time pressure information. On the basis of the single chip microcomputer and the LabVIEW for data processing and display, improving the real-time control of hydraulic support.

Introduction

Coal industry got a great development in recent years, but coal mine accidents still occurred frequently.For example, January this year in ZhuJi mine ,Huainan Mining Group, anhui province,happening a downhole caving accidents which many miners are trapped.As such cases occur frequently, the development of coal industry is greatly affected and restricted.

At present, the roof support in mostly adopts the hydraulic support while the factors such as strata movement and mining work, making the roof pressure constant change. So hydraulic support pressure's real-time monitoring is requirement.Most of the existing hydraulic support work, pressure is monitored by the recording instrument for monitoring which connected on the support column that required staff to go to working face to get the data so it is difficult to learn the current pressure on the hydraulic support[1].For this problem, this paper designed a mining hydraulic support pressure monitoring system based on LabVIEW, which can achieve real-time monitoring pressure of the hydraulic support.Therefore ,effective measure can be timely taken when a special circumstances happened.

System structure

The pressure of the hydraulic support can be read through the pressure sensor, then the pressure would be transmitted to the corresponding data collection which would preprocess the information.After that,the information would be show on the display.The information would be sent to the monitor host through center station,then the data in LAN can be compared with the collected pressure while center station would achieve real-time monitoring, fault alarm, key data record query and other functions[2].The overall block diagram is shown is Fig 1.

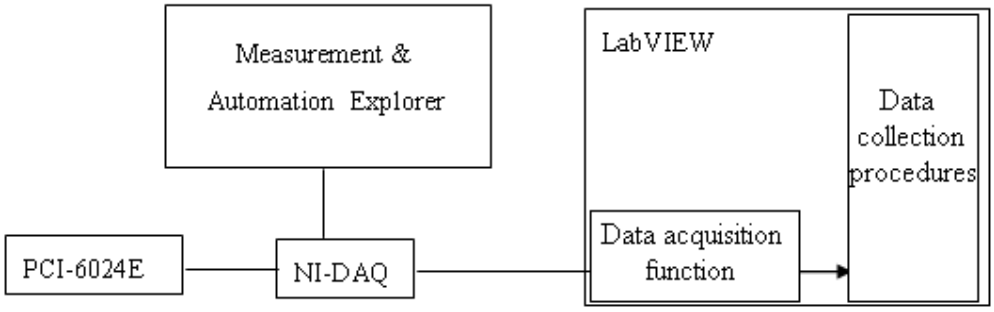

Fig 1 The overall block diagram

The hardware design

The microprocessor

AT89C51 microprocessor is chose(produced by ATMEL company)in this system , which belong to the MCS - 51 series micro-controller.System composed of C51 series single chip microcomputer and AT89C51 do not need without extension program, which make it widely used.

Data acquisition card

PCI - 6221 data acquisition card is a 16-bit resolution, 250 ks/s sampling rate, 2 road 12 analog input, eight digital I/O lines and two 24 bits counter which through USB interface power supply.It is suitable for mining work under the record and environmental testing, at the same time, can also meet the needs of the measurement of this system.

Pressure sensor

Pressure sensor selection: PTG501 strain type pressure sensor which electing high stability and high precision resistance strain gauge sensor chip as transmitter, SMT process including a complete set with zero and full range compensation which could convert the measured pressure into standards electrical signals,such as 4 ~ 20 mA, 0 ~ 5 VDC, 0 ~ 10 VDC, 0.5 ~ 4.5 VDC . The structure is whole sealing , which would make the product of the impact resistant ability, overload ability, such as sealing performance improved greatly, the product the highest pressure can be up to 150 MPa[3].

The choice of strain gauge and layout

BF 120 metal foil strain rosette is elected as the elastomer strain gauge which has good linearity, high fatigue life, small creeping and strong anti-jamming capability.The value is 120 Ω, sensitivity coefficient is 2.0.

Strain gauge is deployed in the maximum strain of the elastomer,which is the roof beam hydraulic support.In order to derivate the signal lines facilitated,a hole is opened on the elastomer.The elastomer should be patch nearly that could reduce the the signal output length[4].Therefore, four slices of strain elastomer are used ensuring the survey of mining hydraulic support, R1, R2, R3 and R4 are used to express the electricity resistance while R1 and R3 express tensile strain gauge and R2 and R4 express compressive strain gauge.In order to obtain larger output sensitivity, full bridge connection is adopted , which is shown in the Fig 2.The initial resistance strain gauge are the same, setting as R.

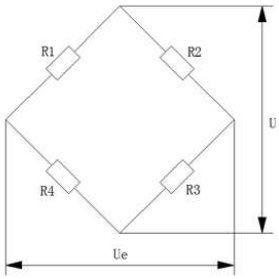

Fig 2 Full Bridge Connection

During the using process, strain gauges resistance is changed as the elastomer's deformation by the effect of load , resistance are supplied as $R_1+\Delta R_1$, $R_2-\Delta R_2$, $R_3+\Delta R_3$, $R_4-\Delta R_4$.As the patch location of strain gauge are symmetry, $\Delta R_1=-\Delta R_2=\Delta R_3=\Delta R_4=\Delta R$ is got.Resistance of strain gauge are as follows:

$$R_1=R_3=R+\Delta R$$

$$R_2=R_4=R-\Delta R$$

Analyze the bridge road, getting the output of the bridge is:

$$U_0=\frac{\Delta R}{R_0}U_e$$

The software design

According to the needs of the real-time monitoring of hydraulic support pressure, landing module, fault monitoring module, data acquisition module, data display module are designed in the

software system. graphical programming language LabVIEW developed by NI company is used in this design which is a general software development platform, not only can provide almost all of the classic analog signal, but also easy to be integrated with data acquisition card.It can improve efficiency at a lower cost[5].The front panel of software system is shown in Fig 3.

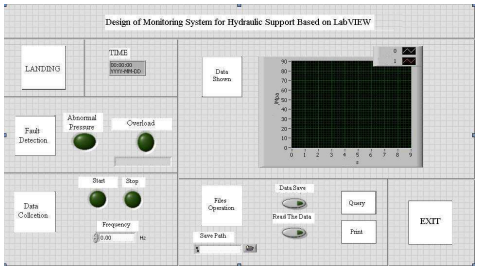

Fig 3 Front Panel

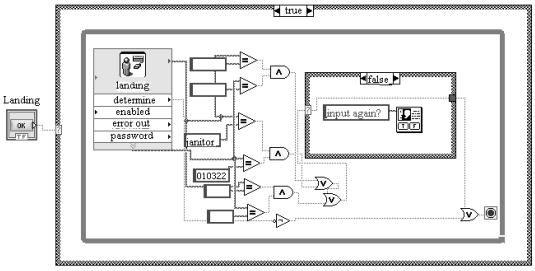

Fig 4 Login module

Login module

In order to prevent the non-working personnel do STH without authorization changes of detection system, a multi-level user management system program is setted in the system.The system only can be operated after a correct password.Administrator logged can add a regular user, thus can effectively avoid the improper operation.Login module's program block diagram is shown in Fig 4.

Pressure real-time display module

This monitoring system can simultaneously monitor ten hydraulic support's pressure ,while each holder's pressure can be displayed the in the beside oscilloscope over time.Pressure real-time display module's program block diagram is shown in Fig5.

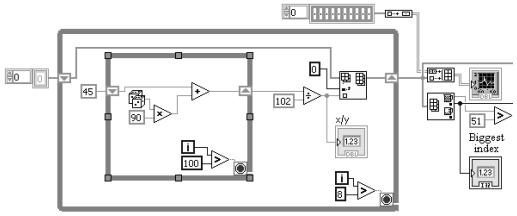

Fig5 Pressure real-time display module

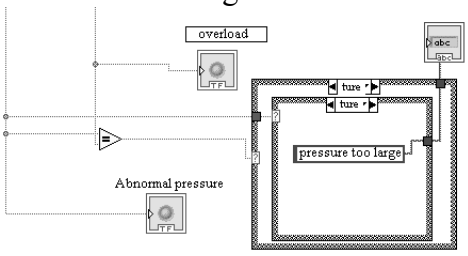

Fig6 Alarm module

Alarm module

Alarm module is an important part of hydraulic support pressure monitoring system.when the hydraulic support's pressure is abnormal or overload, abnormal pressure and overload indicator will light up that reminding the exception occurs to operators.Effective measures can be timely taken to avoid accidents.Alarm module's program block diagram is shown in Fig 6.

Conclusion

A mining hydraulic support pressure monitoring system has been developed based on LabVIEW in this paper which can vividly reflect the mining hydraulic support real-time working condition.In this way,the real-time pressure could be got that proposed an effective and feasible method for the area of fully mechanized working face's pressure monitoring .

Keywords: Laser induced fluorescence, Confocal arrangement, Nonconfocal arrangement

Abstract. Laser induced fluorescence (LIF) detection technique is one of the most sensitive detection method in micro total analytical systems (μTAS) as its good monochromaticity, strong collimation and high optical density. It is widely used in biochemical analysis systems and the detection limit could reach 10^{-9}-10^{-12} mol/L. Due to the important role in μTAS, different optical structure arrangements of LIF detection techniques were continuously developed. We reviewed the recent progress of the optical structure arrangement and the applications of the LIF detection techniques.

Introduction

Recently, μTAS has gained much interest for high-efficiency separation of biological samples such as DNA fragments, amino acids and proteins. μTAS currently mainly rely on one of the six major detection techniques: fluorescence, electrochemical (EC), chemiluminescence (CL), UV-Vis absorbance, massspectrum and Nuclear Magnetic Resonance (NMR). Because of the high sensitivity and selectivity, LIF is one of the most preferred detection techniques to μTAS, particularly in chip-based capillary electrophoresis (CE) systems. Currently, the LIF detection systems are homemade in many laboratories. They usually consist of a laser excitation source, a laser excitation optical arrangement, a fluorescence collecting optical arrangement and a photosensitive detector. When the laser excitation optical with the fluorescence collecting optical is coaxial, its termed as 'confocal arrangement ' and the vice versa is termed as 'nonconfocal arrangement '.

Traditional confocal LIF arrangement

The confocal LIF arrangement mainly consists of a dichroic mirror, microscope objective, lens groups, pinhole, etc[1-7]. The laser passed through an optional filter, a beam expander, then is reflected by a dichroic mirror and focused in the separation channel by a microscope objective. Meanwhile, the fluorescence is collected by the microscope objective, was passed through the dichroic mirror, then was focused by the lens groups onto a pinhole located at the focal point and was detected by a photomultiplier tube (PMT). Currently, the confocal LIF arrangement that can be used for some commercial instruments (such as the Agilent Bioanalyzer 2100) is available.

Mathies and their coworkers [8-10]firstly introduced the confocal LIF technique into μTAS using high-speed DNA sequencing in capillary array electrophoresis. Ocvirk et al.[2] demonstrated a series of biological assays on-chip by confocal LIF detection. 300 fM fluorescein (S/N=6.1) was measured in continuous-flow mode and 1 pM fluorescein (S/N=5.8) was detected in the capillary zone electrophoresis. Zhu et al.[11] obtained the limit of detection (LOD) of 66 fM (S/N=5.8) for sodium fluorescence by reducing the background noise of the confocal LIF detection. Since the excellent detection limits is obtained, the confocal LIF detection for microfluidic-based analysis systems is applied in single-molecule detection [1,3,12]. Schiro et al.[12]used two-beam line-confocal detection geometry for measuring the total mobility of individual molecules in continuous-flow CE separation.

Though the confocal LIF arrangement has the advantage of high sensitivity and wide suitability, the vast size and complex optical structure is a major challenge for the development of

the miniaturization and integration. For overcoming the shortcoming, the bulk conventional lasers[13,14] are replaced with the diode laser [4,15,16]under keeping high-sensitivity detection. In order to the further miniaturization of microfluidic systems, light-emitting diode (LED) should be an excitation source in replace of the diode laser. Dang et al.[17] used the LED confocal fluorescence detection in microfluidic chips. The LOD for APTS-labeled glucose was about 1.98×10^{-8} mol/L (S/N=5.8).

The nonconfocal LIF arrangement

Compared to the confocal LIF arrangement, the nonconfocal LIF arrangement is more simple and easy to build, which mainly consists of a microscope objective, lens groups, pinhole, etc. Some typical bevel incident laser optical arrangements for the microfluidic chip were reported[18-22] . The laser beam impinged upon the microchip at a 45° angle from the microchip surface and parallel to the separation channel. The fluorescence was collected in a direction perpendicular to the microchip surface. Xu et al.[23] reported a LIF detection system based on a line laser beam to assist the alignment with the micro-channel, which simplified the optical structure and reduced the difficulty of building and operating. The LOD of 1.284×10^{-10} M fluorescein isothiocyanate(S/N>12) was obtained.

In order to reduce the background interference generated from reflections and refraction, the layouts of the laser excitation and fluorescence collecting optical arrangements were continuously researched. Fu et al.[24] developed an orthogonal optical arrangement for microfluidic chips. Using a laser beam perpendicular to the chip, the fluorescence was collected from the microchannel through the sidewall of the chip, which effectively reduced the background noise level resulting from scattered excitation light. The LOD of 1.1 pM fluorescein (S/N=3) was obtained. Yang et al.[25] reported small-angle (20°) optical deflection system from the collinear configuration, which eliminated the interference from scattered excitation light, reflection and refraction light generated from the microfluidic chip. The LOD of FITC was estimated to be 2 pM (S/N = 3). Li et al.[26] reported a similar LIF detection system with a small-angle (18°) optical deflection from collinear configuration with silver mirror coating detection window, which greatly enhanced fluorescence intensity. The LOD of 0.5 pM FITC (S/N=3) was obtained.

Incorporating optical fibers into the μTAS is also a good approach used to simplify the optical system by minimizing the number of required optical components. Fang et al.[27] reported a simple nonconfocal LIF arrangement for the chip-based systems. The laser beam was reflected and focused to the separation channel by a 7-cm-focal length concave mirror from below the chip at an incident angle of 45°. The fluorescence was collected perpendicular to the surface of the glass chip by a 2-mm-diameter optical fiber positioned immediately below the chip. Li et al.[28,29] used a multimode optical fiber to transmit the laser beam to the detection point and the PMT to detect directly the fluorescence without the collimation, collection optics and mirrors.

Conclusion

As a traditional optical mode, the confocal arrangement has high sensitivity and wide suitability, which is often applied to single-molecule fluorescence detection. The nonconfocal arrangement has the advantage of simple structure and easy to miniaturization, also got the favour of the researchers. Unfortunately, the size of the LIF detection system is large relative to the size of the microfluidic chip，which is a major challenge for the development of the miniaturization and integration. To overcome this problem, the small and compact optical components, such as small light source (high-output LED) or micro-lens, should be further introduced to the μTAS. Integrating micro lens on the microfluidic through the means such as etching should greatly reduce the volume of the optical system. At the same time, some optical components were replaced by optical fibers, which benefits the integration of the μTAS.

Keywords: Detecting, Ultra low Carbon and Sulfur, Steel, Infrared Absorption Method

Abstract. The detection of carbon with the contents ranging from 0. 000 5 % to 0.010%, and of sulfur with the contents ranging from 0.000 2% to 0.010%, has become an inevitable requirement for steelmaking process control. Due to the extreme low carbon and sulfur contents, using infrared carbon sulfur technical analysis has lower peak value than the background value of the instrument, and it is difficult to control the best analysis conditions of obtained valid signal; in addition, the small errors brought by crucible blank, sample weight, and uniformity of the samples may have great impact on the detection results. To solve this technical problem, this study gives up the single point calibration applied by infrared absorption method, but uses linear calibration method to detect ultra low carbon and sulfur contents in steel, which effectively meets the demand of manufacturers on the development of high-value-added products, and provides reliable data for production.

Introduction

Carbon and sulfur are the routine test items of steel products. Standards such as ASTM E 1019[1] and ISO 15350[2] are applicable for the detection of 0.005%～4.3% carbon contents (mass fraction, same as bellow) and 0. 000 5%～0. 33% sulfur contents. Along with the fast development of production and scientific research, the steel manufacturing today has shown a trend of diversified and lean production. Production scale of ultra low carbon and sulfur steel has been increasingly growing, which raises higher demand on the detection of ultra low carbon and sulfur. The detection of carbon with the contents ranging from 0. 000 5 % to 0.010%, and of sulfur with the contents ranging from 0.000 2% to 0.010%, has become an inevitable requirement for steelmaking process control. Due to the extreme low carbon and sulfur contents, using infrared carbon sulfur technical analysis has lower peak value than the background value of the instrument, and it is difficult to control the best analysis conditions of obtained valid signal; in addition, the small errors brought by crucible blank, sample weight, and uniformity of the samples may have great impact on the detection results. Although there are reports on detecting ultra low carbon by using spark source atomic emission spectrometry [4][5], but the requirements on the conditions for such detection is extremely high, also with high costs. Since a lot of factors may affect the detection of ultra low carbon and sulfur contents, this detection has long been taken as a challenge[6]. To solve this technical problem, this study gives up the single point calibration applied by infrared absorption method, but uses linear calibration method to detect ultra low carbon and sulfur contents in steel, which effectively meets the demand of manufacturers on the development of high-value-added products, and provides reliable data for production.

Test Methods

Put crucible with ultra low carbon and sulfur into a muffle furnace; after burning 2h under the temperature of 1 000℃; after cooling down, it is placed into a dryer for future use. Preheat the infrared carbon sulfur analyzer, make the analyzer in a normal operation state, and set the best analysis parameters. Clear the inlet and outlet of the combustion furnace, replace magnesium perchlorate and alkali asbestos, open the switch of carrier gas and power gas, and check the air tightness of combustion furnace.

The circular blank value measurement method is employed to measure the blank values [7][8] of carbon and sulfur. Take 2. 000 g of fluxing agent into crucible with ultra low carbon and sulfur, select the sample name of "Blank" and default input mass of 1. 000 g, and raise the crucible supporting to conduct the analysis. After two times of measurements, and over 3 times of analysis, at least 3 results with good repeatability are chosen; then the average total blank value is calculated, and it is entered into the analyzer. The analyzer will automatically deduct the blank value during the detection later.

Put the processed crucible with ultra low carbon and sulfur on a balance scale, take (0. 600±0. 025)g sample into the crucible, evenly spread 2. 0 g of tungsten granular on the sample, and conduct the analysis in infrared carbon sulfur analyzer.

Conclusion and discussion

1. Selection of Calibration Method

In the experiment, the single point calibration method with single standard sample is applied, but the accuracy of this method can not be guaranteed when the contents of the elements to be measured in the samples have large deviation with calibration standard value. To solve this technical problem, the linear calibration method is employed with multiple standard samples (at least 3 samples) to conduct the linear calibration based on the range of carbon content of 0. 000 5 %～0.010％ and the range of sulfur content of 0.000 2%~0.010% in the steel production,. By eliminating the analytical deviation caused by individual causal factors, the analytical range has been expanded notably, and this calibration can meet the requirement of quality monitoring during routine production.

2. Selection of sample weight

Sample weight test is conducted by taking different quantities of iron standard substance AR-673[C:0.0005%±0.0001,S:0.0011±0.0002%] according to test method. The result shows that, along with the increase of sample weight of cutting shape samples, the intensity value will become higher. However, the increase of sample weight may lead to incomplete combustion, decreased liquidity and an unmelted sample. Meanwhile, the splash occurs, which may increase pollution degree of the combustion furnace, and thus may affect the measurement result. Experiment result shows, the sample weight is controlled at (0.600±0.025)g.

3 Selection of fluxing agents and their dosage

The experiment investigates the effect of different fluxing agents such as tin and tungsten granular on the detection result [9]. The result shows that, different fluxing agents have small impact on the detection result, but have certain impact on the detection process. The pollution degree of various links, such as combustion furnace and gas routes is notably increased when adding tin granular. Tungsten granular is selected as fluxing agent, for tungsten can react with oxygen at the temperature of 400℃ to generate tungsten trioxide, and its oxidation process releases huge amount of heat, which can increase the calorific capacity of hot-melting substance. The generation of tungsten trioxide is conductive to the release of carbon dioxide and sulfur dioxide, and the volatilization of tungsten trioxide increases the diffusion rate of carbon and sulfur, which makes them sufficiently oxidized and increases their liquidity. It is concluded that, tungsten granular is conductive to the detection of carbon and sulfur.

Proper fluxing agent dosage can completely melt down sample without splash. In experiment, since the carbon and sulfur contents in the sample are low, the sample weight is increased. Properly increasing the tungsten granular dose can effectively promote the fluxing, but along with the increase of tungsten granular dose, the pollution degree of gas route also increases, and the trailing effect is also getting worse. The tungsten granular dose of this study is 2. 000 g.

4. Selection of minimum analysis time and comparator level

Sample analysis time is determined by minimum analysis time and comparator level. Too long duration of analysis leads to unnecessary analysis delay, but insufficient analysis time may lose effective signal. Comparator level of analyzer is a constant 5 plus a percentage of the peak value. A large number of experiments have been conducted on analysis of ultra low carbon and sulfur contents, and the experiment results show that, since detection signal is low and the fixed constant of the instrument is relatively high. Therefore, it is of no use to set up comparator level. The sample analysis time is determined by minimum analysis time.

Figure 1 is the peak shape of minimum analysis time 30s of carbon, and figure 2 is the peak shape of minimum analysis time 35s of sulfur. By analyzing the integral peak shape, it is found that, the integral completion time of detecting ultra low carbon and sulfur contents is above 25s.

Therefore, integral time of 25-40s is chosen for a series of experiments; see the table 1 for data.

Tab. 1 Influence of the minimal analytical time on analytical results

minimal analytical time	average w/%	
	C	S
25	0.002 63	0.001 23
28	0.002 91	0.001 55
31	0.002 92	0.001 80
34	0.002 99	0.001 92
37	0.002 99	0.001 90
40	0.003 00	0.001 88

Table 1 shows that, along with the increase of minimum analysis time, the analyzed value increases, and the measured values of carbon have no significant change when the minimum analysis time is between 28s and 30s; when time exceeds 34s, the measured value of sulfur has no significant change. The minimum analysis time of carbon is 30s and the minimum analysis time of sulfur is 35s.

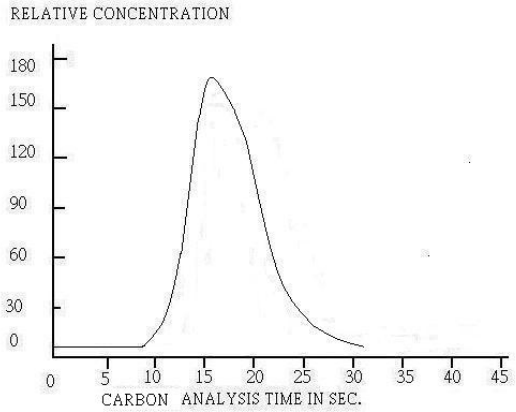

Fig. 1 Peak shape of minimum analysis time of carbon

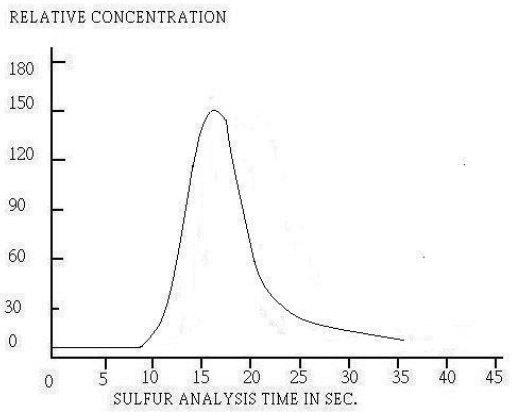

Fig. 2 Peak shape of minimum analysis time of sulfur

5. Working curve and detection limit

Take 0.600 g of standard substances to conduct the detection. Each item is measured over 3 times, and the linearity ranges of carbon and sulfur of 0.000 5%～0.003 5% and 0.000 8%～0.004 8% are calibrated respectively. Under experiment conditions, 11 times of parallel detections for the blank values are conducted. The detection limits of carbon and sulfur are calculated and they are 0.000 235% and 0.000 068 % respectively.

6. Precision test

A piece of ultra low carbon and sulfur sample is selected. Its surface is processed with milling machine, and drilling machine is used to get the drilling powder. The parallel detections of samples are conducted for 9 times with the selected analysis procedure. The average values of carbon and sulfur are calculated and they are 0. 001 82% and 0. 005 20% respectively; the relative standard deviations are 2. 9% and 3. 9% respectively.

7. Analysis of standard samples

According to the experiment method, 4 standard samples of ultra low carbon and sulfur are analyzed, and their results are illustrated in the Table 2.

Tab. 2 Analyt. results of standard samples %

samples	C		S	
	Standard value	Measured value	Standard value	Measured value
CRM No.C1a	0. 003 5	0. 003 4	0. 004 0	0. 003 9
LECO 502-402	0. 002 9	0. 002 7	0. 004 8	0. 004 7
LECO 502-348	0. 001 4	0. 001 5	0. 000 8	0. 000 9
AR-673	0. 000 5	0. 000 4	0. 001 1	0. 001 2

The experimental conditions of this detection method such as detection conditions, fluxing agents, sample weight, minimum analysis time, and comparator level are tested, and a simple,fast, accurate, and a reliable detection method for ultra low carbon and sulfur contents in steel is established by using linear calibration method. This detection method can meet the demand of production.

Research Progress of Detection Method of Sulfur in Iron-Base Alloys

Bayati, M.R., Pengyi WEI

Department of Materials Science and Engineering,

North Carolina State University, Raleigh, NC 27695, United States
email: pengyiwei5101@sina.com

Keywords: Sulfur; Iron-base alloys; Analytical method; Summary

Abstract. The paper summarizes the research progress of analytical method of sulfur element in iron-base alloys as of 2012. Major analytical methods for sulfur element in iron-base alloys include infrared absorption, photoelectric direct reading spectrometry, inductively coupled plasma atomic emission spectrometry, ion chromatography method, mass-spectrography, and electrochemical method. The paper also predicts the future trend of the analytical methods for sulfur element in iron-base alloys.

Introduction

Sulfur is a harmful element in iron-base alloys, and it can generate a “hot shortness” effect to iron-base alloys, namely, in case of thermal deformation, workpiece cracks. So it is very harmful. Surlfur may also undermine the mechanical property of iron-base alloys, and especially degrade their fatigue limit and abrasive resistance significantly, which affects the lifespan of iron-base alloys. High sulfur contents may cause such negative effects as welding difficulty and degradation of corrosion resistance.

However, addition of appropriate amount of sulfur into some iron-base alloys with specific specifications may improve the cutability, machinability, and magnetic property. The sulfur contents of free-cutting iron-base alloys can reach over 0.2%. Sulfur contents of ordinary steel are usually no more than 0. 05％; high-quality steel and tool steel no more than 0. 045％, 0. 03％; high-grade fine steel no more than 0. 02％. Solid solubility of sulfur in iron-base alloys is extremely small, but it may form various types of sulfide, such as FeS, MnS, VS, ZrS, TiS, CrS, NbS, etc. when there are large amount of manganese in iron-base alloys, the major form of its existence is MnS, and the secondary form is FeS. Sulfur is one of low content elements in iron-base alloys, and also the element that is listed as the important detection item in iron-base alloys.

The purpose of analysis of sulfur element in iron-base alloy is to meet the demand of new product development, and to improve the product quality of iron-base alloys. Therefore, control of each detection step, and reducing the facts which may cause errors during the detection of sulfur may has great significance for guiding production, developing new products of iron-base alloys, and controlling the quality of iron-base alloy products. In recent years, sulfur analyses, especially the analyses and reports of sulfur in metallurgical industry show an increasing trend. Along with the development of the research on high-performance alloy, and advancement of refining techniques, It requires to accurately detect the ultra low sulfur content in iron-base alloys(mass fraction less than 0.001％). However, limited by many factors such as blank, instrumental sensitivity, and lack of low sulfur standard samples, sulfur detection has long been the subject of the exploration for years. The paper mainly discusses the progress of the detection methods of sulfur element in iron-base alloys, including infrared absorption, photoelectric direct reading spectrometry, inductively coupled plasma atomic emission spectrometry, ion chromatography method, mass-spectrography, and electrochemical method.

Infrared Absorption Method

Currently, the most widely applied sulfur analysis of iron-base alloys in production is infrared absorption method. The experimental device for detecting surlfur in iron-base alloys by using this method is a special analyzer integrated with the units of infrared source, gas absorption pool, high temperature furnace (usually high frequency induction heating furnace), and detector. After heating and melting in high temperature, sulfur in the sample generates SO_2 in oxygen, and the contents of sulfur could be measured by using infrared absorption method. In recent years, the infrared gas analysis technique has shown a fast development, and various analyzers using high frequency induction heating combustion and infrared spectroscopy absorption principle have also been developed. Infrared absorption method has become the standard method of ASTM E1019-11[1] and ISO 15350--2000[2] to measure the sulfur in steel. Detection of sulfur by using high frequency combustion infrared absorption method usually should consider the factors of crucible (sample weight, aridity, and electromagnetic induction), fluxing agents (types, ratio, adding sequence, and adding amount) reagent for purifying gas (anhydrous magnesium perchlorate), setting of blank values, etc. Jiang Qicui [3] discussed the factors to affect the detection repeatability and accuracy, when conducting detection of trace sulfur in steel by using high frequency combustion infrared absorption method. In the experiment, a molecular sieve was connected to the gas inlet so as to remove the moisture in the gas, and an external mounting oxygen purification furnace was equipped to further eliminate the moisture in oxygen. 1.5 g of tungsten granular was added as fluxing agent each time. The result showed that the sulfur release curve was smooth, and the accuracy of the analysis result was high. Kunio Takada et al. [4] improved the conditions of detecting trace sulfur in pure iron by using infrared absorption through experiments with various conditions, and lowered and stabilized the sulfur blank values of crucible, fluxing agent, and gas. Then the sulfur blank value is deducted, so as to achieve the objective of detecting trace sulfur contents. Zhou Jun [5] detected the sulfur in cast iron by using CS-344 Infrared Carbon Sulfur Analyzer. Through experiment, the best analysis conditions for sulfur detection in cast iron, such as fluxing agents, sample weight, combustion analysis time, were identified. By applying LECO CS-444LS Carbon Sulfur Analyzer, Hong Zhian[6] conducted sulfur detection in ultra pure iron, high purity steel, and desulfurated silicon steel, and the capture method and regular approach were used for analysis. Capture method was to add a SO_2 trap with a special molecular sieve on original CS-444 Carbon Sulfur Analyzer. Molecular sieve could capture the sulfur released from the sample at normal temperature. It concentrated the contents of ultra low sulfur. When completing the capture, the molecular sieve was instantaneously heated to high temperature. By taking helium as a carrier gas, it can send the SO_2 captured in the molecular sieve to the detector for detection. The result showed that, the analysis result of capture method was relatively accurate, and this method has been used for detecting the sulfur contents of high-purity iron(mass fraction 0. 000 224%), high purity steel (mass fraction 0. 000 563%) and desulfurated silicon steel (mass fraction 0. 000 940%). Sun Ying et al.[7] also made the research on the conditions of using LECO CS-444LS Infrared Carbon Sulfur Analyzer for sulfur detection in steel（mass fraction less than $10\mu g \cdot g^{-1}$） and concluded that the system blanks of the analyzer mainly come from oxygen, laboratory environment, detector noise signal, and accumulation of tungsten dust of combustion system. Ashino T.[8] et al. made special processing to the fluxing agents used for detecting trace sulfur and achieved good effect. According to the method and procedure of uncertainty detection and evaluation of analytical test, Li Gang et al. [9], by introducing uncertainty components, evaluated the factors such as repeated measurements, standard substances, electronic scales, analytical instruments, working curve fitting, etc. According to the calculation, the composite uncertainty of sulfur was 0. 00146, effective degree of freedom 253. 0, and expanded uncertainty 0. 0024. The calculation of uncertainty provided guidance for the detection of sulfur contents in cast iron by using CS-902T Infrared Carbon Sulfur Analyzer in laboratory.

In detecting trace sulfur contents in iron, sometimes the system blank value is almost same with the analyzed value of a sample, even higher than analyzed value of a sample. Therefore, the

correct use of blank value method will directly affect the accuracy of the analytical result of trace sulfur contents in samples. The latest development of detecting blank values is The Cycle Detection of Sulfur Blank Value(CMSBV)[10] created by Jianhuan WEI et al.. Firstly, the blank value reduction and stabilization steps are carried out; then The Cycle Detection of Sulfur Blank Value (CMSBV) is employed to measure the total blank value; Finally, the measured total blank values are entered into the detector, and the detector will automatically deduct the blank values. The blank value impact analysis value can reach 0. 000 03%, and the impact of sulfur blank value to measured value of sample could be completely eliminated.

Photoelectric direct reading spectrometry method

Featured with high speed, high precision, low detection limit, high degree of automation and intelligence, and less interference, photoelectric direct reading spectrometry has become a basic means for modern metallurgical analysis. Currently, steel industry mainly applies photoelectric direct reading spectrometry for analysis of iron-base alloys, especially for analysis of the most important non-metallic element, sulfur. However, since its structure is not evenly distributed, the analysis result is not accurate. In recent years, the reports of the studies on detection of sulfur element by using photoelectric direct reading spectrometry have been mainly concentrated in the aspects of condition optimization and new method improvement. Cai Jijie et al.[11] used direct-reading spectrometer to optimize various analysis parameters, and it has achieved high precision and accuracy when making a fast analysis of the chemical components of stainless steel sheet and thin belt. The light source of modern direct-reading spectrometer usually uses spark light source with high-repetition-rate, which has high excitation frequency and high-energy pre-combustion function. By using direct reading spectrometry, Li Gang et al. [12] studied the impact of the relative intensity of standard sample to the accuracy of the result of detecting sulfur element in cast iron. The research adjusted the relative spectral line intensity of sulfur generated from two standard samples of both high and low sulfur contents, so that the system error of the standard value of the standard sample lower than the system value was eliminated, and thus the accuracy of sulfur element analysis in cast iron samples was effectively improved.

Inductively coupled plasma atomic emission spectrometry

With its advantages of high sensitivity, low detection limit, good stability, less interference, wide linear range, fast analysis, simultaneous and sequential detection of multiple elements, Inductively coupled plasma atomic emission spectrometry(ICP-AES) has become an indispensable important analytical method in the research field of metallurgical analysis. In analysis of iron-base alloys, it can detect over 50 kinds of elements, but few cases of using ICP-AES method to measure sulfur in iron-base alloys have been reported. The key for using ICP-AES method to detect sulfur is the pre-processing of samples. Sulfur exists in iron-base alloys in the forms of sulfides. When using reducing acid or hydrogen nitrate to dissolve samples, sulfur is easy to generate H_2S and to vaporize, causes serious loss of sulfur, and thus affects the detection results.

Combined with flow injection（FI）technology, Yamada[13] used ICP-AES method to detect the sulfur contents in high purity iron, which greatly improved the detection efficiency, with the detection limit of $0.3\mu g \cdot g^{-1}$. Li Jie et al. [14] studied influential factors of using ICP-AES method to detect the sulfur content in steel samples, such as pre-processing of samples to be detected, selection of analysis conditions of analyzer, matrix effect, etc. Potassium chlorate was added into oxidation sample with the mass ratio of 5:95, so that sulfur did not vaporize in the form of H_2S during pre-processing. After experiment, it is found that, iron matrix may affect the detection result. Matching between working curve with sample matrix is applied to eliminate the interference of iron matrix; finally a proper detection method of detecting sulfur in low alloy samples (mass fraction >0.001％) is identified. No only is this method easy to operate, but also solves the traceability problem of constant value analysis process of samples. Xu Jianping[15] used IRIS-Advantage ICP spectrograph to establish the method for detecting sulfur contents in steel, with

the detection limit of 0. 000 24%; He also discussed the loss of sulfur in various dissolving system and the deduction method for the blank values of low content sulfur (mass fraction<0.01%), identified Potassium chlorate--nitric acid--hydrochloric acid mixed acid dissolving sample, prevented the sulfur loss during the sample decomposition processes, and effectively improved the accuracy of the method; From the comparison, it is found that, by using standard substance to draw working curve, the accuracy of the method could reach the level of Barium sulphate gravimetric method, but the analysis speed could be improved over 10 times.

Ion chromatography

By virtue of speediness, sensitiveness, good selectivity, less interference, and simultaneous detection of multiple samples, Ion chromatography (IC), as an instrumental analysis techniques, shows a rapid development and is widely applied in analysis and detection fields. Currently, the Ion chromatography (IC) is widely applied in the detection of anions in liquid samples [16]. It is reported that the detection limit of SO_4^{2-} has reached to $ng \cdot L^{-1}$ level. However, when combustion method is applied to process steel sample, the sulfur release rate and conversion rate is not stable, with high blank value. Therefore, before applying Ion chromatography, the separation and purification with activated aluminium oxide is conducted, in order to eliminate the metal ion. By taking activated alumina column as preliminary separation column, Hu Jingyu [17] used acid soluble samples, to quickly separate the trace sulfur from matrix of steel sample and make a quantitative recovery. 2.25 $mmol \cdot L^{-1}$ of potassium hydrogen phthalate solution was used as mobile phase, and Shimadzu CLASS-LC10 ion chromatograph is applied to conduct the detection by using single column ion chromatography. By using sample pre-treatment technologies such as microwave digestion and activated alumina adsorption column separation, Lan Yuwei et al. [18] established microwave digestion--activated alumina adsorption column separation--ion chromatography method to detect trace sulfur in steel. The linear range of the method is 0. 2～100 $mg \cdot L^{-1}$, with detection limit of 0. 12 $mg \cdot L^{-1}$. The method is used to detect the sulfur contents in standard steel samples, and its relative standard deviation is 3. 3%～6. 7%. This method is suitable for the detection of a large number of samples.

Mass-spectrography

Mass-spectrography is an important instrument analytical method [19-20], but it is rarely applied in metallurgical analysis, especially the analysis of iron-base alloys. Early in 1979, Watanabe[21] has established isotopic dilution mass spectrometry (IDMS) to detect the sulfur contents in steel and high temperature alloys. Sample was processed by using nitric acid and hydrochloric acid solution samples, and then the bromine was used to oxidize the sulfur into SO_4^{2-} for detection. Finally the sulfur contents in the standard sample(mass fraction 0. 004%～0. 329%) was detected, and the relative standard deviation of measured value was less than 1.5%. Grégoire[22] made a in-depth research on the combined technology between Inductively Coupled Plasma Mass Spectrometry(ICP-MS) and electrothermal vaporization (EVT) such as micro waveguide--inductive coupling, and thus established a method for detecting sulfur element; and he further developed a detection method for trace sulfur in steel, called ETV-ICP-MS, with the detection limit of $0.05 \mu g \cdot g^{-1}$[23]. By applying Thermal ionization mass spectrometry (TI-MS) combined with isotope-dilution analysis, Kelly[24] established a method for detecting low sulfur contents in steel, with the detection range of 0. 000 6%～0. 011 9%. By using this method, Kelly successfully detected 6 kinds of standard substances of National Institute of Standards and Technology (NIST) of USA.

Electrochemical method

Analytical method of identifying substance contents by detecting the solution conductance is called conductometric analysis method. The principle of conductometric analysis method to detect

the sulfur element contents in iron-base alloys is as the following: Under high temperature of 1 250～1 350℃, iron-base alloy sample is burning in oxygen flow, and sulfur element is oxidized to generate O_2; then SO_2 is introduced into sulfur absorption pool with oxidant solution (usually potassium iodate). Then oxidation-reduction reaction occurs between SO_2 and potassium iodate, to generate SO_4^{2-}：

$$KIO_4 + SO_2 + H_2O = 2H^+ + SO_4^{2-} + KIO_3$$

The conductivity in the sulfur absorption pool changes after absorption, and its variables has functional relationship with the sulfur contents, so that the mass fraction of sulfur in steel sample could be calculated. Yang Jiahe [25] used a DFY-12 conductometer to establish a conductometric analysis method to detect the sulfur contents in alloy steel, high temperature alloys, stainless steel, ordinary steel, and spheroidal graphite cast iron. Li Yuangui et al., [26] took hydrogen peroxide as the absorbent solution of SO_2, to detect the sulfur (mass fraction 0. 021%) in carbon steel.

Electrochemical analytical methods for detecting the sulfur in iron-base alloys also include coulometry analytical method. Kurusu et al. [27] established coulometry method to detect sulfur element in iron-base alloys, with the detection range of 0. 000 07%～0. 010%. Jiang Xiumei et al. made research on the influential factors of coulometry method for detecting sulfur, and proposed corresponding optimization method.

Outlook

In recent years, research on analytical method for detecting sulfur in iron-base alloys has made significant progress. The analytical methods have shown the features of diversification, and the sensitivity and selectivity of these methods tends to be increasingly higher. In production sector, with its advantages of high accuracy, wide application range, and good stability and reliability, especially with its notable advantage in detecting ultra low sulfur contents, Infrared Absorption is the most widely applied method; by optimizing the detection conditions such as blank value measurement method, fluxing agents, oxygen purity, integral time, crucible, etc., Infrared Absorption method is further improved, and the research in this regard is also underway.

Studies on sulfur detection method were mainly focused on ICP-MS methods, on the detection of trace sulfur, and the application scope of the method is expanded by combining the new technologies such as flow injection, chromatographic separation, electrodissolution, etc. From the literature, it can be seen that, analysis of sulfur in iron-base alloys has been gradually converted from chemical methods and single element analysis to instrumental analysis and multiple elements simultaneous analysis. Looking into the future, the study on detection of sulfur contents in iron-base alloys will have breakthrough in the aspects of using fast, accurate, and highly automatic methods and instruments, as well as in realizing online detection of sulfur during the smelting process of iron-base alloys, so that the detection of sulfur in iron-base alloys will be upgraded into a higher level.

[a]dfmtb@163.com, [b]tbma@aust.edu.cn

Keywords: flexible manipulator; vibration control; positive position feedback; direct velocity negative feedback; piezoelectric

Abstract. The positioning accuracy and work efficiency of flexible manipulator is seriously affected by its vibration. Therefore, vibration control of single joint flexible manipulator is studied by using an improved PPF algorithm based on LabVIEW and piezoelectric technology. Firstly, the improved PPF algorithm principle is introduced. Then, the experiment process is discussed in detail. Experimental result shows that the improved PPF algorithm can effectively control the first two modal vibration of flexible manipulator. The control effect is close to 14 dB and improved nearly 4.5 dB compared with PPF algorithm.

Introduction

LQG, LQR, variable structure control, independent modal space control (IMSC), positive position feedback(PPF) and speed negative feedback (DVFB) and other methods are widely used in piezoelectric active vibration control of flexible structures. However, LQG, LQR algorithm depends on accurate mathematical model so that its application become complicated[1].Variable Structure Control usually shows high frequency fluttering in the vicinity of the slide plane origin point, so it affects its practical application. IMSC has the advantages of clear physical concept and easy to implement, but it needs multiple piezoelectric actuators in multi-modal control[2]. PPF algorithm has the advantages of simple and not sensitive to overflow, but there are dual character in the compensation damping ratio[3], contradictory effects between robustness and low order modal control modes[4].Direct velocity feedback method has the unconditional stability, but it is easy to control overflow[5].In order to overcome the shortcomings of traditional PPF algorithm, PPF and negative feedback velocity method are combined in this paper in order to further improve the system damping. Experimental results of active vibration control for piezoelectric flexible manipulator show that this method could have better stability and control effect.

Principle of PPF-DVFB algorithm[6]

The principle of PPF control based on position measurement and alignment control is that position coordinates of the controlled plant are positively fed back to the controller, then the controller voltage is acting on the actuator to suppress the vibration of the structure [3]. According to the report in the literature [6], PPF-DVFB algorithm theory containing a low pass filter is shown as Fig.1.

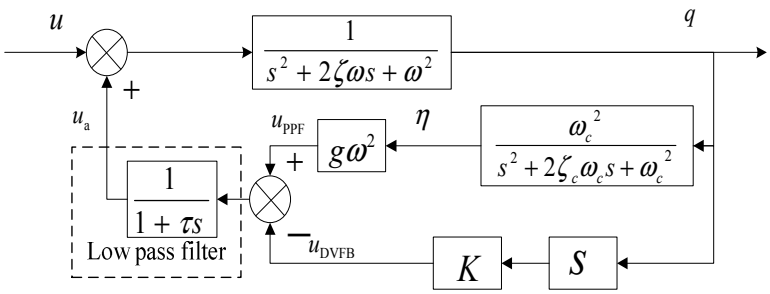

Fig.1 Principle of PPF-DVFB algorithm

In the above, q and η are the structure displacement and compensation coordinates. ζ and ζ_c are the structure and compensator damping ratio respectively. ω and ω_c are the structure and the natural frequency of the compensator. g is PPF algorithm for the feedback gain. u is the excitation signal. u_{PPF} is the input voltage of PPF controller to the actuator. u_{DVFB} is input voltage of DVFB controller to the actuator. K is feedback gain of DVFB algorithm. s is Laplace transform factor. τ is a positive number.

Determination of the structural parameters

Taking into account the vibration energy of systems focused on the previous order modal, two modal of manipulator was selected as the main control objective. When the stepping motor is rotating at a constant speed under the action of the driver, the manipulator vibration will be excited. Amplitude-frequency characteristic curve is obtained by Fourier transform for the response signal of the piezoelectric. Then, the frequency of first two modals can be observed as 15Hz and 81Hz. Then the first two modal damping ratios of system are calculated for 0.09 and 0.04 by the frequency response method as the literature[7].Finally, according to the literature [8] method, the first two modal compensation damping ratio is set to 0.4 and 0.2.

Experiment of active vibration control

Experimental system establishment. Experimental device shown as Fig.2 consists of computer, NI CRIO-9024 system, Nanjing Buddha company's HVP-300B-type amplifier, DT-2A type low pass filter, 300mm×52mm×1.5mm aluminum robotic arm, 50mm×30mm ×0.2mm piezoelectric and Changzhou Wan Tai company's 57BYG type stepper motor and its control system. The manipulator is driven by a stepper motor. Because the torsional stiffness of stepper motor is much larger than the stiffness of manipulator, boundary conditions approximate cantilever beam[3]. The position of the largest strain for first two vibration modal is the root of manipulator, so the piezoelectric ceramic (PZT) are pasted on this location symmetrically. Taking into account the continuity of stepper motor rotation and minimizing the volatility of step process, drive frequency of stepper motor is set to 128 (maximum frequency division), step angle is set to 1.8 degree, driving frequency of controller is set to 2500Hz.

A pair of piezoelectric is pasted symmetrically in the experiment, one is used as sensor and the other is used as actuator. NI 9229 AI DAQ card is used to acquire piezoelectric sensor signal. Then the signal is supplied to the CRIO system. After the signal processing of algorithm by LabVIEW software, the control voltage is sent to NI 9263 AO card, then the signal passes through a low pass filter (frequency be set to 100Hz) to the input of the power amplifier, and Finally, the output voltage of power amplifier drives the piezoelectric actuator to achieve manipulator vibration suppression.

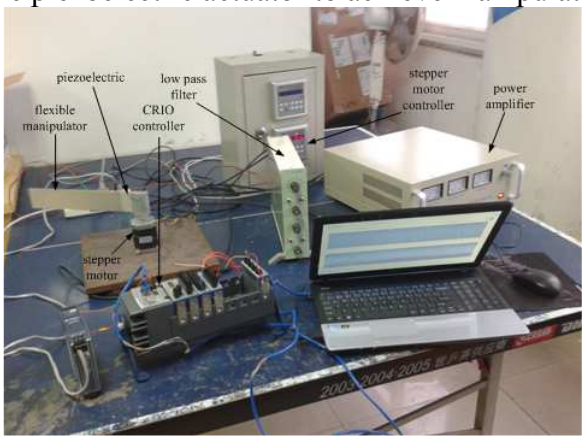

Fig.2 Experimental photo of flexible manipulator vibration control

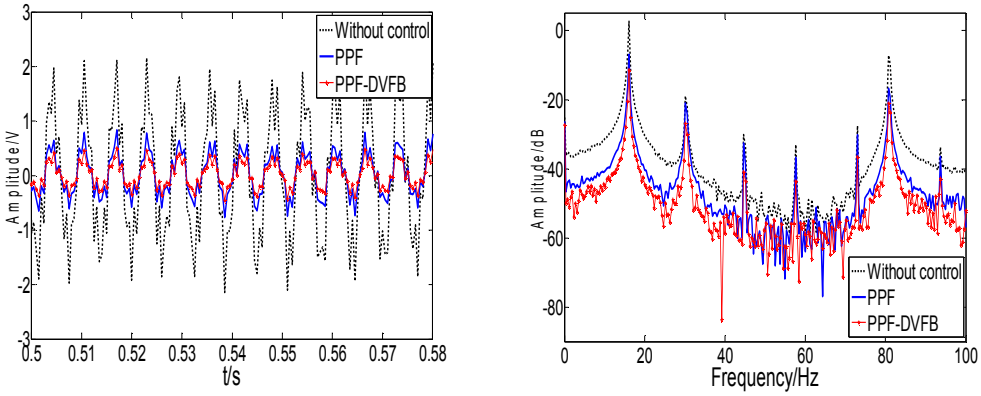
Software Programming. The LabVIEW software based on CRIO works at scan interface mode, control cycle clock to be synchronized with the scanning engine, and sampling rate is set to 2KHz. Velocity negative feedback coefficient is set to 0.05 and PPF gain coefficient is set to 0.9 by many experiments, other modal parameters are set as described in Section 2.Considering the impact of

input and output Delay, the delay module is increased in the software program. According to calculating method in reference [9],the compensation time is 0.0005s. The output voltage limit of AO card is ± 10V, so the signal limiter is added.

Experimental results and analysis. Vibration suppression effect of flexible manipulator is shown as Fig.3 by two different control methods when it is driven at a constant speed. when the control voltage amplitude is increased to about 50V, for the first order modal, PPF-DVFB control effect reached 14 dB and PPF is 9.5 dB, meanwhile, for the second order modal, PPF-DVFB control effect is 13.7 dB and PPF is 9.3dB. It is shown that the control effect of PPF-DVFB algorithm could obviously be better than the PPF algorithm, especially in some other frequences. The main reason is that every compensator PPF controller is set up for a particular mode, so it has only effect on specific frequency, but DVFB has attenuation effects for every frequency components. There are other modal harmonic frequency in addition to modal frequency as shown in Fig.3(b), this phenomenon of harmonic vibration is caused mainly due to the stepper function to some extent, PPF algorithm effect is poor in these harmonic frequences, but PPF-DVFB method can still hold good effects.



(a) Time Domain (b) Frequency Domain

Fig.3 Time domain and frequency domain response of flexible manipulator

Summary

In this paper, PPF and PPF-DVFB algorithms are used to achieve vibration control for first two modal of flexible manipulator. Experimental results show that PPF-DVFB algorithm either in modal frequency or in other modal harmonic frequencies has better control effect compared with the traditional PPF algorithm, Which can further enhance the working stability of the flexible manipulator.

The Wind and Light Power Supply System Controller in the Mobile Base Stations

Hong Ma

Nanjing Institute of Industry Technology,Nanjing China

mh_purple@163.com

Keywords: wind,light, controller, power supply

Abstract: With the rapid development of economy, the consumption of energy increasing year by year, the conventional energy is facing increasingly draining.The wind and light power supply system controller in the mobile base stations is a kind of power supply management system,used the wind and light, which have the biggest and the most development potential renewable energy and new energy technology at present.That especially suitable for mobile communication base station,and remote sensing, remote control base station power supply and operation environment. The controller can reduce run maintenance cost, improving the quality of communication and system management level,and the efficiency of the whole.

I INTRODUCTION

With the rapid development of economy, the consumption of energy increasing year by year, the conventional energy is facing increasingly draining,urgently needs a new type of clean renewable energy. The wind and light, which have the biggest and the most development potential renewable energy and new energy technology at present,and they are an inexhaustible renewable energy.

In recent years, with the rapid development of mobile telecommunication in China, network scale has become the first status in the world, the communications industry has become a pillar industry to promote the development of Chinese economy. As the network scale expands unceasingly, the communications equipment quantity and energy consumption are increasing. Effective energy saving and emission reduction measures not only is contributing strength for the country, helping reduce operating costs for enterprises, improving operational efficiency,and enhancing competitiveness in the whole business competition environment.

According to the characteristics of the power supply technology used the wind and light, energy management technology is the actual researched and developed of the design,i.e.,improving energy efficiency and economy of power supply system. It is easy to causing the communication interrupt such as local area communication network,once the failure occured in the base station.The design can be implemented for remoting centralized monitoring for the base station power and environmental parameters, for grasping the real-time system information and failure information,particularly suitable for unattended base stations.

II POWER SUPPLY TECHNOLOGY USED THE WIND AND LIGHT

Due to the attention of the environment and energy, all countries carried out researching and developing of new energy. Europe is in the leading level in this field, especially in wind power and solar power technology has made a lot of achievement. Europe mainly has the following research in the field of new energy,such as large grid electric field and related technology. The difficulties of domestic research in the field of new energy is lack of funds,combined with the actual demand, mainly research focused on control algorithm of wind power and solar power and the small new energy system.The research on small power supply system used the wind and light are brought to the attention of the people,and limited to research aspect including system composition and control, the selection of equipment and system simulation, etc in the domestic.

Chinese renewable energy storage is very rich,especially in the solar and wind power. Wind and solar power has natural complementarity,as strong sunlight during the day, the solar energy is

rich, wind energy abundant in the evening, and wind and solar power also has the very good complementary effect in the summer and winter.The characteristics of complementary can be used to a stable power supply. As an independent power supply system, has considerable advantages,used in outdoor lighting. It not only achieving the purpose of energy saving,but also simplifing installation procedures, convenienting application and maintenance,because do not need to connect the grid and solve the problem of circuit laying, saving investment of equipment.

Power supply used the wind and light combined with the advantages of solar photovoltaic power and wind power generation system, solving the poor power supply problem by solar photovoltaic power at night or rainy weather, and improving the continuity, stability,reliability of the power supply system. The system mainly is suitable for the regions where wind energy, solar energy resources are relatively abundant.

The main characteristics of power supply technology used the wind and light as follows:

(1) using the complementary characteristics of wind energy and solar energy, and making full use of natural resources, realizing the power output day and night, can obtain relatively stable total output, improving the reliability of the power supply;

(2) the short construction period, installed flexible;

(3) Compare the independent wind power and photovoltaic power system, under the condition of the same power supply, can greatly reduce the capacity of the energy storage battery;

(4) Through the reasonable design and matching of power system, the power supply by the wind/light system can be implemented, can obtain good social and economic benefits, realizing very good energy saving effect.

III TECHNICAL DESIGN

The working environment of mobile communication base station power supply is more and more poor,making the power supply must be reliable operation under various temperature and humidity conditions,and withstanding the erosion of dust, insect and lightning. These requirements make the design of the key factors is rectifier equipment,standby power supply and power distribution circuit in environmental protection,safety,installation and maintenance and other aspects.

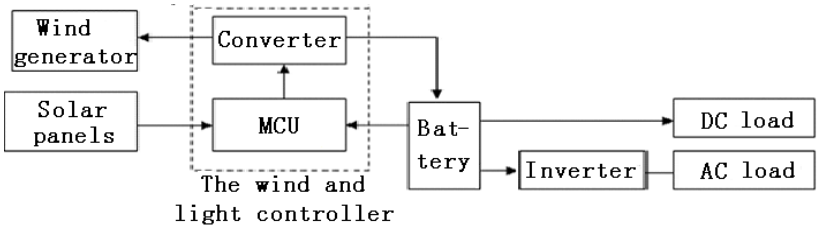

Figure 1 Structure diagram of the wind and light power supply system controller in the mobile base stations

The design plan of the wind and light power supply system controller is illustrate in figure 1, including wind generator, solar panels, the wind and light controller,battery and inverter. Control chip using PIC16F877A MCU, which is responsible for the control of the whole system,and is the core part.The peripheral circuit including voltage and current sampling circuit, power driving circuit, protect circuit, communication circuit, auxiliary power supply circuit, etc.

1 The main circuit

Main circuit is made up of two independent of buck circuit which parallel on the output side, one is photovoltaic power generation system, the other one is wind power system. As shown in figure 2.

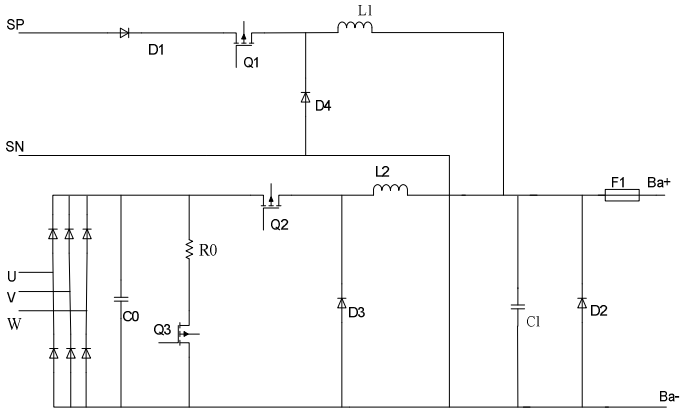

Figure 2 Hardware main circuit structure

(1) photovoltaic part

Solar photovoltaic panels is another Generate electricity part.It is responsible for converting sunlight into electricity.

maximum power point voltage of photovoltaic panels is 17.6 V, open circuit voltage is 21.6 V. Photovoltaic parts used four solar photovoltaic batteries, output voltage range is 60 ~ 90 V.

(2) Wind power generation part

The wind power generation part is the one of the parts of the wind and light power supply system controller in the mobile base stations, consisting of the wind turbine,transmission mechanism and generator, etc.

The role of generator in wind power generation systems is converting mechanical energy into electrical energy, that is converting wind energy into mechanical energy, transmission mechanism transfer mechanical energy, finally converting mechanical energy into electrical energy. Generator direct impact the performance, the efficiency and quality of power supply of the conversion process. Therefore, It is mportant task for wind power generation part that selecting high reliability, high efficiency, good control and power supply performance.The types of generator of the small wind and light power supply system has the following kinds,typically three-phase permanent magnet synchronous generator, DC generator, electromagnetic alternator, claw pole generator, reluctance generator and induction generator, etc.

2 Battery

The battery is the important auxiliary equipment of the wind and light power supply system controller in the mobile base stations. Three functions of the battery in the power generation systems such as: The first is the energy storage,as the natural wind and sunshine is unstable, the battery can store extra electricity after supply load under the wind, sunny conditions, in the case of poor wind, sunshine,only can output power to the load. Second is stable voltage, the speed of the wind decide rotational speed and output voltage of wind power generator,as the change of natural wind is great,strong randomicity,making voltage floating range is very large,through battery adjusting, power supply can be stabilized;Third is the wind and light power supply, wind power and photovoltaic power are two independent power system,and power strength of them some times are a big difference,thus using the battery can combine the two electricity, realizing complementary.The rationality of battery capacity configuration will impact technical and economic indicators of the small wind and light power supply, if choose the small capacity, the excess electricity system sends out will not be stored, and if choose the big capacity,one will increase investment,two will make the battery may be long in the condition of insufficient charging, directly affecting the efficiency and life of use. Commonly used batteries mainly such as lead-acid batteries, alkaline nickel battery and iron nickel battery.The lead-acid battery has advantages such as low cost, reliable performance, high safety, and the technical progressing and improving.

Over charge and discharge of battery will affect its life, when the battery discharge serious, the voltage is too low, also can damage the battery, thus the design using the method of disconnect the discharge circuit through the relay circuit,and opening the discharge loop again when voltage is

back. In order to keep the system stable work,the design also uses discharge voltage hysteresis control,preventing the battery excessive discharge.

IV. CONCLUSION

This design is based on the application of new energy technology, the research conclusion can adapt to the rapid development of mobile communication field, the research achievements in energy conservation and environmental protection,the new generation of information technology has extensive application value,and achievements diffusion has the good economic and social benefits.The design can remote check the status of the wind and light, and can automatic transformation according to the set of parameters, checking the battery state of the residual capacity and discharge protection mode of battery voltage. The design with features such as preventing the surge, preventing short circuit, preventing reverse, preventing overload, etc,and controlling fan braking through automatic and manual mode, temperature compensation, and the temperature probe automatic recognition,thus this design can avoid to cause too much compensation.

Keywords: Service innovation; Dynamic mechanism; LOGINK; System dynamics; In-tree

Abstract. According to system dynamics and in-tree structure, we choose National Transport & Logistics Public Information Platform (LOGINK) as a research object. Then, considering new service concept, new customer interface and new delivery system, its dynamic mechanism of service innovation is studied. Finally, we establish the corresponding dynamic relationship model and deduce dynamic relationship equation.

Introduction

LOGINK stands for National Transport & Logistics Public Information Platform, which is mainly founded by China's Ministry of Transport. Having a nationwide and internationally switching network exchanging basic logistics information and portal web site, LOGINK achieves reliable, safe, efficient and smooth information exchange between related logistics information system and platform and unifies information exchange standards, which effectively promotes the ex-change of information and resource sharing between each link of logistics industry chain [1].

The generation of LOGINK service innovation is a complicated course, which can be analyzed through system dynamics and in-tree structure theory. Based on opinions that structure determines behavior, system dynamics establish models from the micro structure of internal system and analyze internal relations between dynamic behaviors and system structure and function using the method of numerical simulation in order to find a solution [2]. According to the core idea of system dynamics, LOGINK service innovation depends on the circulation of “flow” in system internals, and the flows forms feedback loops to connect key variables and other variables, which presents the system structure whose each other and mutually restrict each other [3].

Mechanism research of factors influencing LOGINK service innovation based on in-tree structure theory

Service concept monitor subsystem. The state variables of LOGINK service concept include basic data exchange, public information services and logistics software.

Basic data exchange can unifies information exchange standards between different kinds of logistics public information platform to avoid isolated island of information, low efficiency of information transfer and high cost.

Public information services can solve these problems such as logistics public information serviceresources in national level are scattered, the demand of logisticsinformation service can’t be met and so on.

The development of the logistics common software can avoid repeated development and construction ofsoftware, meanwhile can mesh with the standardization.

The in-tree structure of service concept is shown as Figure 1.

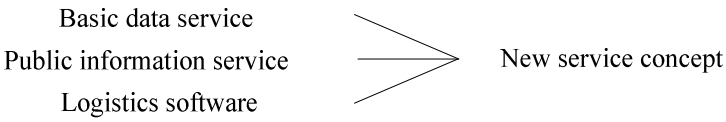

Fig.1 The in-tree structure of service concept

The in-tree structure of basic dataservice is shown as Figure 2.

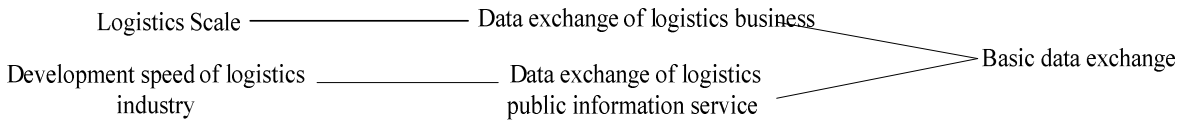

Fig.2 The in-tree structure of basic data service

The in-tree structure of public information service is shown as Figure 3.

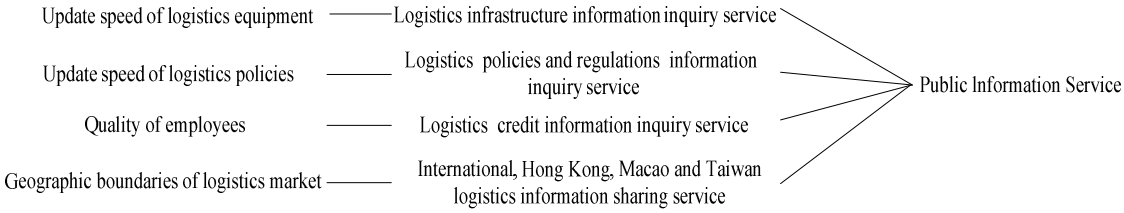

Fig.3 The in-tree structure of public information service

The in-tree structure of logistics software is shown as Figure 4.

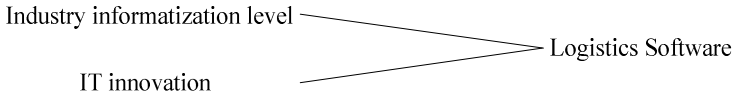

Fig.4 The in-tree structure of logistics software

Based on the above analysis, the dynamic relationship model of service concept can be shown in Figure 5.

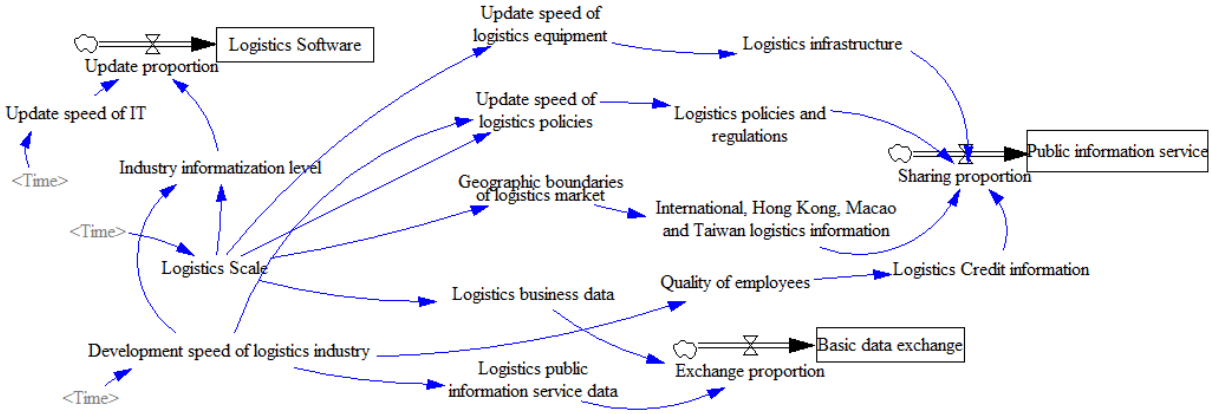

Fig.5 Dynamic relationship model of service concept

According to the dynamic relationship model of service concept, the dynamic relationship equations are listed as follows.

$$LSOFT=UP*IT+UP*IIL \quad (1)$$

$$TPIS=SR*（LII+LIPR+IHMT+LCI）= SR*（LERS+LPUS+LMGB+SQ） \quad (2)$$

$$BDE=ER*（LBD+LPISD）= ER*（LS+LIDP） \quad (3)$$

Customer interfacemonitor subsystem. The characteristics of LOGINKservice interface are public good, open and shared. The customer interface includes access interface and user interface. The in-tree structure of customer interface is shown as Figure 6.

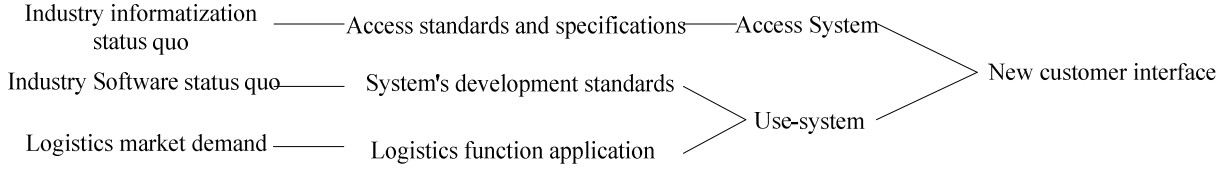

Fig.6 In-tree structure of customer interface

Based on the abovestructure, the dynamic relationship model of customer interface can be shown in Figure 7.

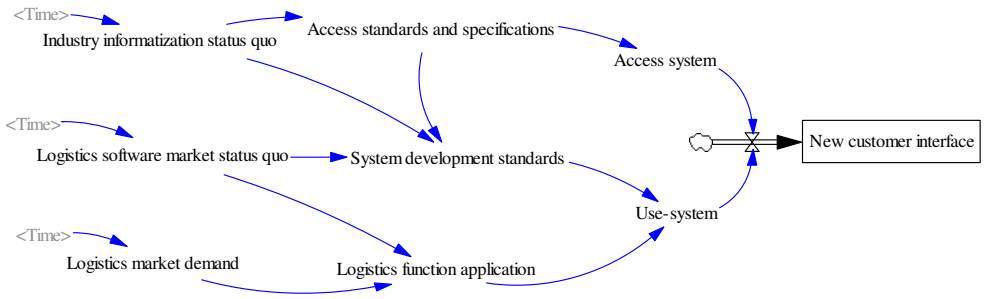

Fig.7 Dynamic relationship model of customer interface

According to the dynamic relationship model of customer interface, the dynamic relationship equation is listed as follows.

$$NCI=ITTS+UTS=ASS+SDS+LFA=IISQ+LSMSQ+LMD \quad (4)$$

Service delivery monitor system. The state variables concerned by service delivery monitor system of LOGINK are technical expert group, management center and joint conferencesystem.

The in-tree structure of technical expert group is shown in Figure 8.

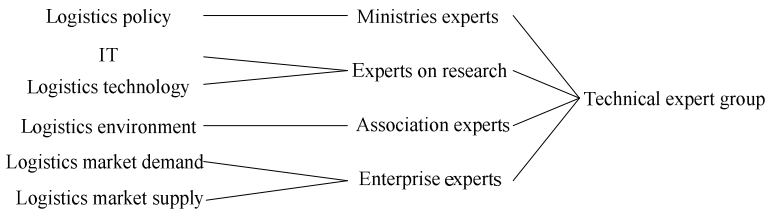

Fig.8 In-tree structure of technical expert group

The in-tree structure of management center is shown in Figure 9.

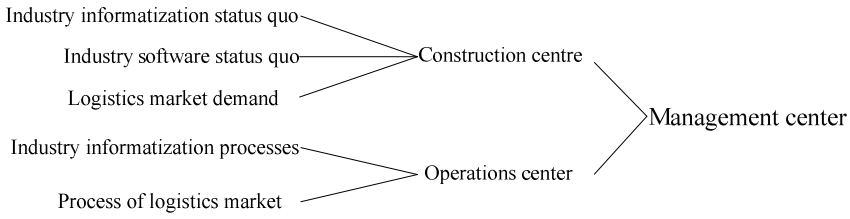

Fig.9 In-tree structure of management center

The in-tree structure of joint conferencesystem is shown in Figure 10.

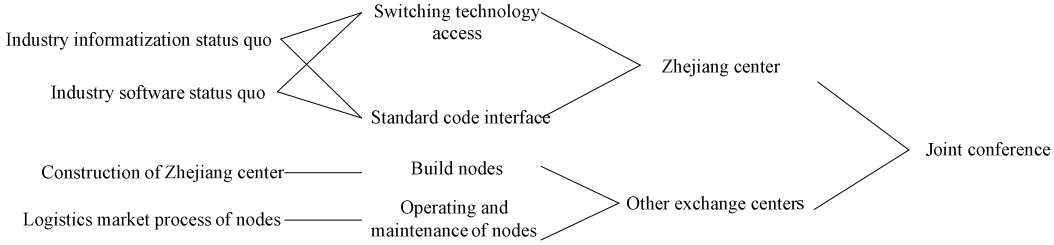

Fig.10 In-tree structure of joint conference system

Based on the abovestructure, the dynamic relationship model of service delivery monitor system can be shown in Figure 11.

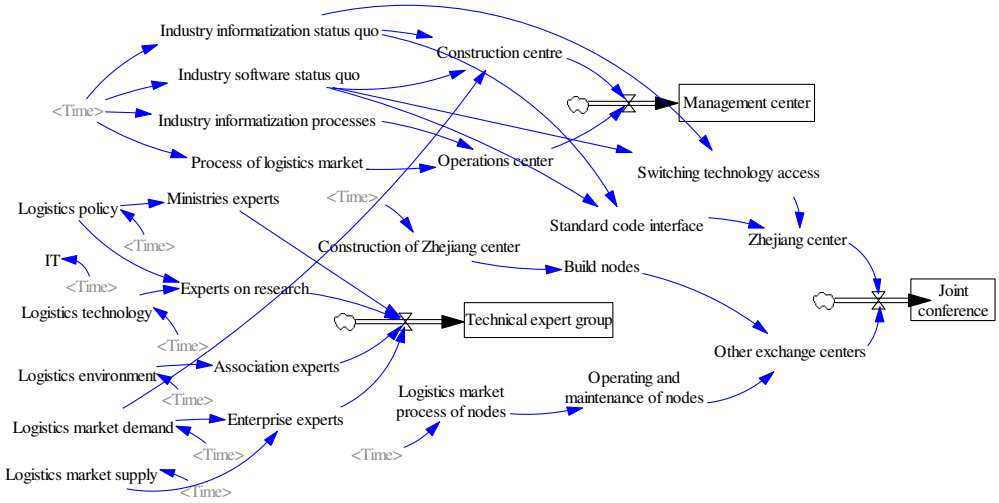

Fig.11 Dynamic relationship model of service delivery monitor system

According to the dynamic relationship model of service delivery monitor system, the dynamic relationship equations are listed as follows.

MC=TCC+OC=IISQ+SISQ+LMD+IIP+PLM (5)

TJCS=ZJC+OEC=STA+SCI+TNC+NOM= 2 *（IISQ+SISQ）+ZJCSC+NLMP (6)

TETG=GE+SE+AE+EE=LP+IT+LT+LE+LMD+LMS (7)

Mechanism research of factors influencing LOGINK service innovation

Combining above analysis about service concept, customer interface and service delivery system, we can get the dynamic relationship model of LOGINKserviceinnovation which is shown in Figure 12.

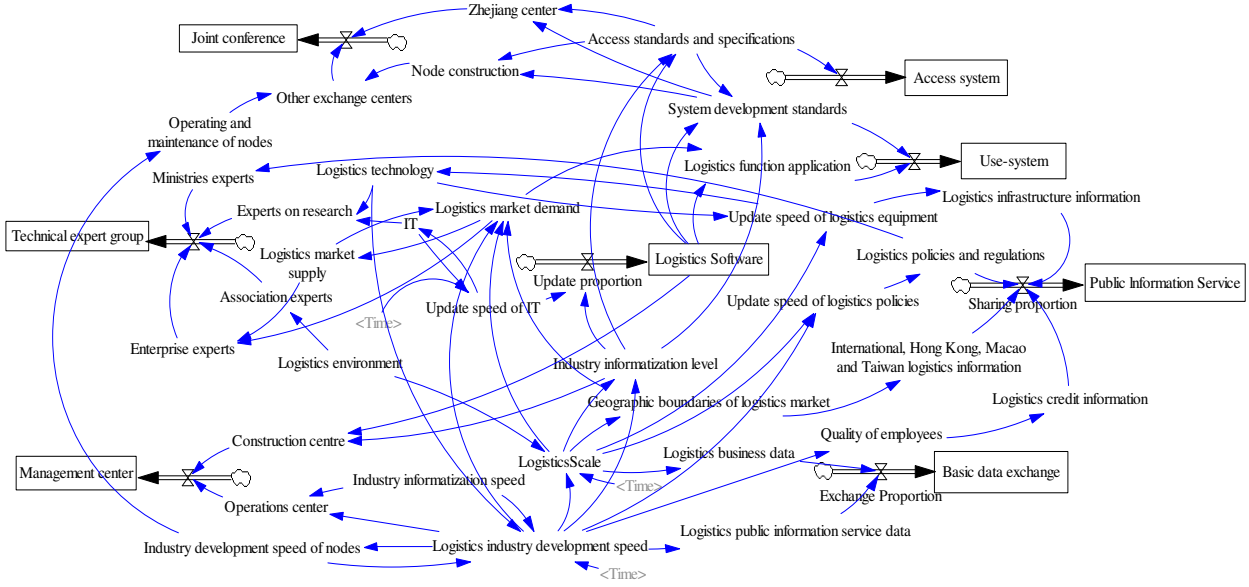

Fig.12 Dynamic relationship model of LOGINK service innovation

According to the dynamic relationship model, the dynamic relationship equations are listed as follows.

JC=OEC+ZJC=HRM+HC+IS+SDS (8)

ETP=MCE+SRE+AE+EE=LPRI+(IT+LT)+LE+(LMD+LMS) (9)

MC=CS+RMS=(IIL+LS)+(IIV+LID) (10)

LS=IIL+ITUV=(LIDV+LS)+IT (11)

BDE=LBD+LPISD=LS+LIDV (12)

CIS=LBSI+LPRI+IGATI+LCI=LEUV+LPUV+LMLB+SQ=(LT+LS)+(LS+LIDV)+LS+LIDV (13)

NUS=SDS+LFA=(IS+IIL)+2LS+LMD (14)

NIS=IS=LS+IIL (15)

Summary

Serviceinnovation of regional logistics information platforms can be generated by service concept, customer interface and service delivery system. Factors influencing LOGINKserviceinnovation include economic environment, policy environment, industry environment, platform strategy, IT, customer, developer, public sector and so on, which together push forward the generation of LOGINKserviceinnovation.

Keywords: numerical simulation; the kinetic energy projectile; moving targets transverse direction

Abstract: When the kinetic energy projectile into concrete target movement, angle of attack can affect the penetration process of ballistic performance, resulting deflection effect, thus affecting the penetration depth. For the analysis of kinetic energy projectile penetrating the lateral movement of the target deflection model, using the finite element simulation software for lateral movement of the target missile penetrates the process of numerical simulation. The results showed that: rigid lateral movement of the target missile and projectile kinetic energy projectile velocity has some deflection effect. Playing the role of the kinetic energy of the lateral movement of the target, the missile body yaw angular velocity increases and then decreases after the first, but not so obvious kinetic energy projectile yaw.

1 Introduction

When the kinetic energy projectile into concrete target movement , angle of attack can affect the penetration process of ballistic performance , resulting deflection effect , thus affecting the penetration depth . When the target projectile penetrates the lateral movement , so playing experience deflection , thus affecting the penetration ability of elastomers .

For the analysis of kinetic energy projectile penetrating deflection lateral movement of the target model , using the finite element simulation software ANSYS / LS-DYNA projectile penetrates the lateral movement of the target process simulation .

2 Projectile translational cause deflection model analysis

When the target projectile penetrates the lateral movement , mainly by two forces . First, because the target has a lateral movement after contact with projectile and target collision , playing the role of lateral impact by the pulling force , the role will generate kinetic energy projectile centroid of torque , the torque acting on the kinetic energy of the projectile , resulting in the occurrence of kinetic Bouncing body deflection ; second , due to the impact force acting on the projectile , playing experience to get lateral velocity , causing its speed direction deflected . As the high-speed impact of stress and strain in the process of the law is more complicated, so here doing the following assumptions: (1) the kinetic energy projectile is rigid ; (2) friction and gravity is negligible; (3) of the kinetic energy of the projectile motion of the target force is always perpendicular the axis of the rod , and the same size .

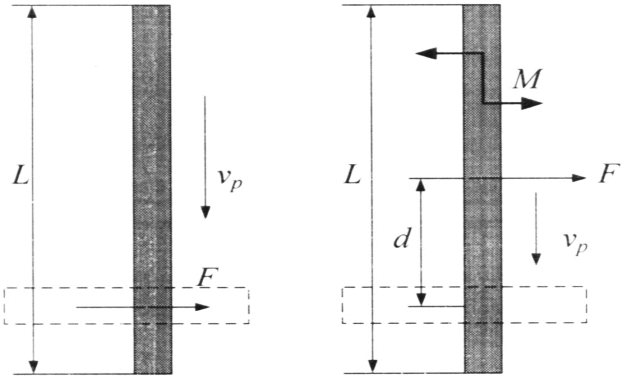
Kinetic energy projectile on target time after perforation force shown in Figure 1 (a). Target of the role of sport at the point of impact pressure . According to Theorem translational force , equivalent to the centroid of the lever , urging dipole moment , the equivalent force in Fig 1 (b) above.

Obtained by the theory of theoretical mechanics

$$M = Fd \tag{1}$$

$$J\frac{d^2\varphi}{dt^2} = M \tag{2}$$

Where: kinetic energy projectile equivalent vertical centroid distance between the front line of action; moment of inertia of the rod to confront the heart; deflection angle for the projectile.



(A) prior to the equivalent force (b) the equivalent force

Fig.1 Kinetic energy projectile on single target time by trying

Assuming no change with time is a predetermined value, then

$$\omega_0 = \frac{d\varphi}{dt} = \frac{12F}{m_p L^2}\left(\frac{Lt}{2} - \frac{v_p t^2}{2}\right) \tag{3}$$

$$\varphi_0 = \frac{12F}{m_p L^2}\left(\frac{Lt^2}{2} - \frac{v_p t^3}{6}\right) \tag{4}$$

Where: piercing process and were shot in the body and yaw angular velocity deflection angle; into kinetic energy projectile length; was piercing time; mass elastomers; was projectile speed.

Were substituted into the formula (3), (4) have

$$\omega_1 = 0 \tag{5}$$

$$\varphi_1 = \frac{FL}{m_p v_p^{\ 2}} \tag{6}$$

Where: deflection angle and yaw angular velocity and were passing through the movement of the target projectile after; for the projectile through the movement of the target time.

F is a constant amount in the assumptions, there is a constant acceleration in the vertical axis of the rod kinetic energy projectile impact in the sports board. When the kinetic energy of the projectile through the tail, the transverse velocity kinetic energy of the projectile is

$$v_x = \frac{FL}{m_p v_p} \tag{7}$$

Assuming the initial kinetic energy projectile velocity constant direction, the direction of the final projectile velocity change the angle of the tangent is

$$\tan\phi = \frac{v_x}{v_p} = \frac{FL}{m_p v_p^2} \tag{8}$$

From Equation (6) shows that, $\tan\phi \approx \varphi_1$, while φ_1 and $\tan\phi$ are very small, and therefore $\phi \approx \varphi_1$.

Thus, the kinetic energy of the projectile into the lateral movement of plates in the process, not only the attitude of the deflection occurs, the direction and speed of change accordingly, both changing the angle of roughly the same, so the final kinetic energy of the projectile velocity direction remains its axial direction, does not produce significant yaw angle.

3 Simulation Study

3.1 model and boundary conditions. The use of ANSYS / LS-DYNA software diameter 10 mm, length to diameter ratio of 12, the speed of 1 500 m / s tungsten alloy vertical kinetic energy projectile penetrating single 5 mm, speed was 100 m / s and 200 m / s for lateral movement of the steel target for numerical calculations. In the theoretical model derivation process, the kinetic energy of the projectile is assumed to be rigid, so the choice of where the kinetic energy projectile rigid material model.

3.2 Process Analysis. projectile deflection due to numerical parameters of each node can only get the objects, the results can not be obtained directly kinetic energy projectile deflection, and the projectile deflection angle is very small, so the use of projectile head and tail nodes lateral distance and relative transverse velocity to the amount of deflection of the elastomer represents the deflection angular velocity. Numerical results of the processing to obtain a kinetic warhead craniocaudal and lateral end of the lateral distance relative speed versus time curve shown in Figure 2, Figure 3.

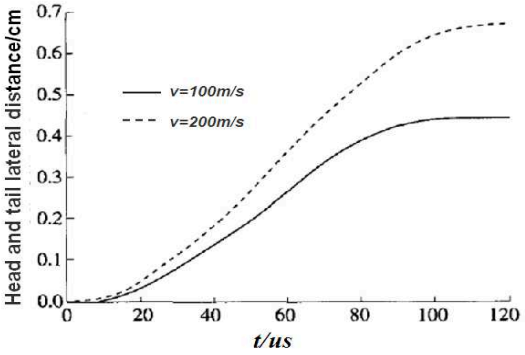


Fig.2 Projectile head and tail lateral distance versus time in Figure

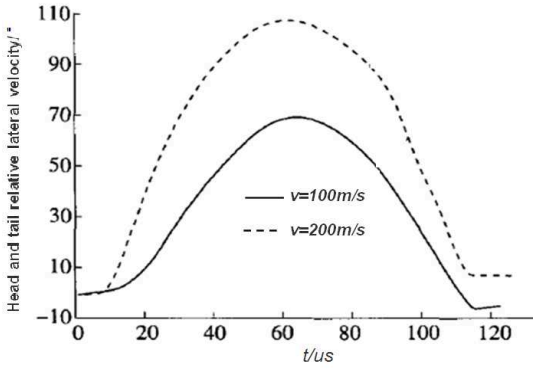

Fig.3 Projectile end to end relationship lateral velocity and time

In Figure 2 and Figure 3 , the target speed of 200 m / s at the top of the curve of the target speed 100 m / s curve can deduce the target speed of 200 m / s the kinetic energy of the projectile impact force is large, so that although a target of lateral forces kinetic energy projectile can be considered approximately constant , but its size and the speed of movement on the target .

Figure 3 represents the deflection trends indirect angular velocity kinetic energy projectile . Can be seen from Figure 3, the yaw angular velocity projectile is then decreased for . This is because the target for the kinetic energy projectile impact on the torque rod centroid positive work on the kinetic energy of the projectile to do first , after doing negative work . 60 is about half the kinetic energy of the projectile through the movement of the target projectile long time , so the two curves in the left and right portions of the approximate time symmetrical shape. Finally, the yaw angular velocity is reduced to about 0 rad / s, the deflection stopped the maximum deflection angle .

3.3 Effect of transverse velocity of the projectile deflection angle . Target effects of kinetic energy projectile kinetic energy projectile deflection not only , but also to obtain a lateral velocity kinetic energy projectile , causing it to deflect the direction of the actual speed . Speed equal to the tangent of the deflection angle of the transverse velocity of the longitudinal velocity ratio. Because time is proportional to the transverse velocity , vertical velocity change is small relative to the longitudinal velocity transverse velocity is small, so the speed of the deflection angle and time was approximately proportional relationship . Deal with the numerical results obtained two kinds of cases, and its speed projectile final deflection angle , shown in Figure 4 .

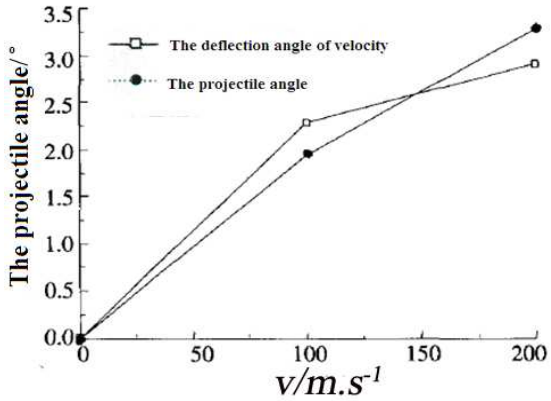

Fig.4 Bouncing body kinetic energy and speed of the deflection angle of the relationship between the target speed

As can be seen from Figure 4, when the certain conditions, the deflection angle of the final elastomer and an elastomer is very close to the speed of the deflection angle, which is more consistent with the deflection model; when the speed is increased, the deflection angle increases, but the two are not directly proportional relationships. Yaw angle difference between the two kinds is the deflection angle of the projectile, since both the size quite close, so very small projectile yaw angle, yaw obvious.

4 Summary

(1) rigid lateral movement of the target projectile and projectile kinetic energy projectile velocity has some deflection effect.

(2) the impact of the movement of the target model are the kinetic energy projectile deflection and numerical calculation process is basically the same, indicating that the theoretical model and numerical calculation with good consistency.

(3) under the action of kinetic energy projectile lateral movement of the target, the projectile body yaw angular velocity after the first increases and then decreases, and finally to 0 rad / s, this time projectile reaches its maximum deflection angle.

(4) The final projectile deflection angle and deflection angle is very close to the projectile velocity, projectile yaw angle is very small, indicating that lateral movement of the target can not make the obvious kinetic projectile yaw.

Keywords: DSC; power difference, municipal sewage sludge

Abstract. The differential scanning calorimetry is a thermal analysis. Under program controlled temperature, measure and input to the relationship between the the sample and the reference's power difference and temperature. The curve which the differential scanning calorimetry recorded called DSC curve. DSC curve in the sample's rate of endothermic or exothermic as ordinate and in temperature or time as abscissa, which can determine a variety of thermodynamic and dynamics parameters, such as specific heat capacity, the reaction heat, thermal changes, phase diagram, reaction rate, rate of crystallization, polymer crystallinity, purity of a sample,etc. The method has a wide temperature range -175 ~ 725 ℃, high resolution, less samples . This topic utilizes differential scanning calorimetry and had a pyrolysis experimental analysis for urban sludge. Due to the rapid development of technology and analyzer's constant improvement, and computer technology's speedy development, DSC plays an increasing role in the sludge treatment field.

Introduction

With the increase of urban sewage treatment capacity and the degree of deepening the water's treatment, sludge as wastewater treatment's secondary pollutant, its production also increased significantly, if handled improperly, or not timely, which will lead to serious secondary pollution. The final destination of the sludge increasingly attract people's attention: on the one hand, the sludge contains heavy metals, pathogens, toxic organic compounds which is difficult to be degraded, and improperly handling can endanger people's health ;on the other hand, the sludge is rich in organic matter and N , P, K and other nutrients, it is hoped to achieve sludge resource utilization.Thus sludge treatment and disposal has become an important environmental issue. The purpose of treating and utilizing sewage sludge is mainly to achieve reduction,stable,harmless and resources.Because it is completely harmless and reduction, sludge thermochemical treatment's status has gradually increased. This topic utilizes differential scanning calorimetry and had a pyrolysis experimental analysis for urban sludge , the type of the precision balance using in the experiment is BT224S.

The reaction mechanism

The sludge pyrolysis process analyzing from reaction process can be divided into three stages:
1)Dehydration stage (room temperature 100 ^{o}C).At this stage, biomass just has physical changes , mainly lose moisture.
2)Solid decomposition stage (100 ~ 380 ^{o}C).This is the main pyrolysis.At this stage, biomass thermal decomposition under anoxic conditions,with the increasing of temperature,various volatiles correspondingly separate out,most of the raw material occurs most mass loss.
3)Carbonization stage (> 400 ^{o}C).At this stage, decomposition occurs very slowly,the mass loss is much smaller than the second stage.At this stage,C-H, C-O bond in coke is further broken,but the volatilization is continuing,coke weight decreases with a slow rate and tend to be stabilized, which resulting in the enrichment of carbon in the residual solid.

Reaction conditions

Try to control the laboratory's room temperature at 15 °C -25 °C, the results of the experience has higher accuracy and repeatability under the constant temperature condition, at the same time, clean sample care and experimental area by ear-insufflating ball before the experiment start, to ensure the accuracy of the experimental results, heating the empty instrument about 30 minutes first when using it.Temperature can be setted to 600 °C, the rate can be setted to 5 °C / min, the thermostat can be setted to 0min. The amount of the sample should not be too much and generally around 20mg will be better. Powdered sample should be compacted. Heating rate generally be setted to 10-20 °C / min .If the heating rate is too high ,the curve will occur drift and resolution will be reduced.If the heating rate is too low,the time of measure will be too long. Before measuring the sample,regulating the instrument by using anhydrous copper. When regulating and measuring, the temperature can be setted to 600 ℃, the rate can be setted to 10 °C / min.

Reaction results and results description

1) The effect of experimental conditions

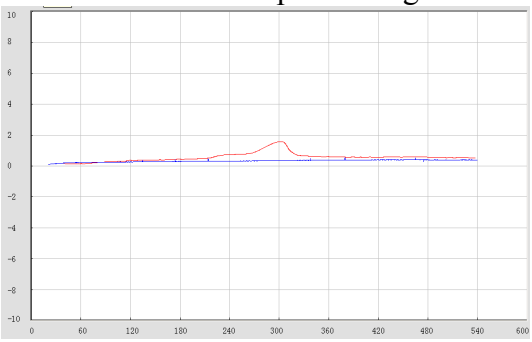
During the DSC , the heating rate has mainly effect on the curve's peak temperature and peak shape. Generally speaking, when the heating rate becomes faster, the DSC curve's peak temperature will be higher, the peak area will bigger and the peak shape will be more sharp. This effect is largely associated with the types of the sample and the types of thermal transition. High heating rates can cause uneven temperature distribution inside the sample. When it exceeds a certain heating rate, the mutative picture in the sample reaction can not be accurately recorded because the system can not quickly respond to changes , in addition, if the heating rate is too fast, it can result in overheating. Furthermore, in order to avoid some test substances occurring oxidation, deoxidation and other chemical reactions during the experience, so different substances should be tested in different atmosphere.

2)The effect of the sample's nature

During the DSC, generally the amount of sample is very small, which about dozens milligrams. If the amount is excessive, the sample's internal heat transfer will be reduced, and the temperature gradient will become larger, which causes the peak shape become larger and the resolution will be reduced.In addition, the granularity has certain effect on DSC, but it is a little complicated. Generally speaking, large particles has greater thermal resistance,which can decrease sample's melting temperature and melting enthalpy. When the crystal sample is ground into fine particles, due to the distorted crystal structure and the decreased grain size, which can also cause similar results. If the powdered sample with static electricity, it dues to the electrostatic attraction between the particles makes the powder agglomerate, which can lead to the melting enthalpy become larger.

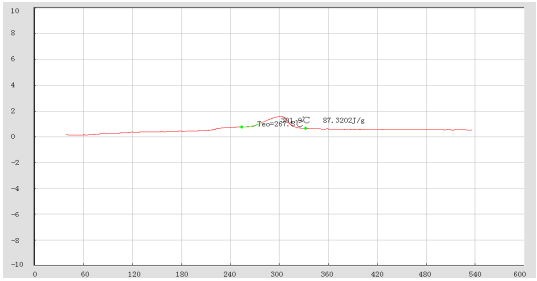
3)The results description

1.1 DSC curves of pond sludge



Sample Name: pond sludge
Sample Quality: 20.0mg
Heating rate: 10 ℃ / min
Gas Name: Air

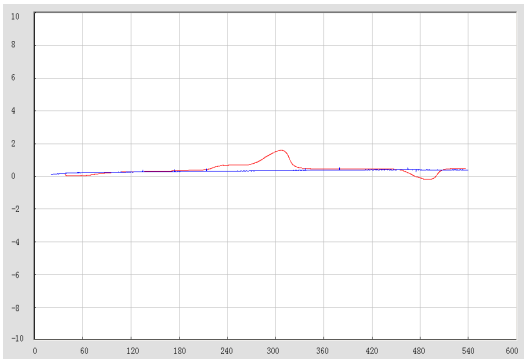
1.2 pond sludge's unit enthalpy diagram



Results description and calculation : As can be seen from Figure 1.1: Overall baseline occurs drift within the allowable range. Sludge pyrolysis has an obvious exothermic peak. From Figure 1.2,it can be drawn that the exothermic peak occurs mainly at 254.8 ℃ -327.9 ℃. In this interval, sludge has thermal decomposition under the hypoxic conditions, with the increase of temperature, all volatiles corresponding separate out and the sludge occurs most mass loss . At this time,after releasing heat and heat air, sludge pyrolysis basically tends to be stable and has no-calorie variations.

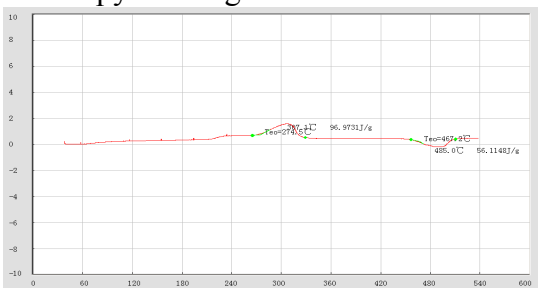
$$Q_1 = 87.3202J/g * 0.02g = 1.746404J$$

1.3 The sludge added calcium oxide DSC map



Sample Name:sludge plus calcium oxide
Sample Quality: 20.0mg
Calcium oxide Quality: 10.0mg
Heating rate: 10 ^{o}C / min
Gas Name: Air

1.4 The units enthalpy of sludge which is added calcium oxide



Results description and calculation

As can be seen from Figure 3.15: Overall， baseline occurs drift within the allowable range. Sludge pyrolysis has a significant exothermic peak and a endothermic peak. Exothermic peak occurs mainly in 266.3 ℃ -329.8 ℃. Because the sludge is dry sludge, so this figure is almost no change before the 266.3 ℃,

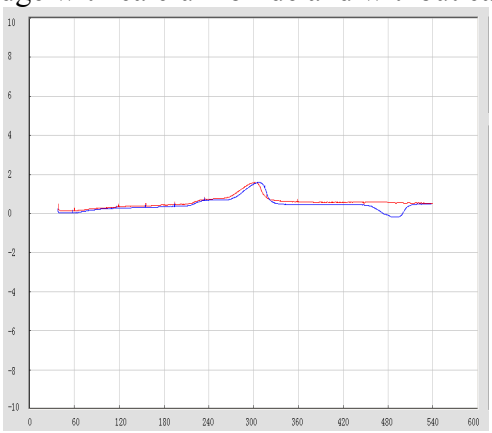
Heat release is:

$$Q_1 = 96.9731J/g * 0.02g = 1.939462J$$

Endothermic peak occurs mainly in 456.9 ℃ -508.9 ℃. And following, there is no heat generated. Heat absorption is:

$$Q_2 = 56.1148J/g * 0.02g = 1.122296J$$

1.5 Comparison of sludge with calcium oxide and without calcium oxide DSC atlas



Comparative results description:

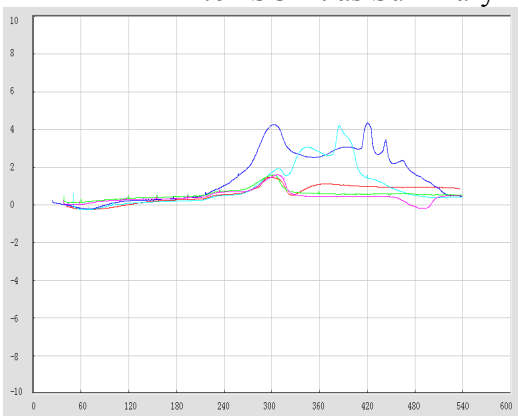
The red curve is the DSC map without calcium oxide .

The blue curve is the DSC map with calcium oxide

It can be seen from Figure 1.5: calcium oxide has no catalysis on sludge.Originally calcium oxide in the pyrolysis process,the chemical properties will not be changed and it means that there is no heat change, but in contrast, I found the experimental curve which added a small amount of calcium oxide began a trough at about 460 ^{o}C, which may be due to the addition of calcium oxide component is impure and it has become a calcium carbonate. According to statistics that the calcium carbonate would decompose at about 500 ℃,.In experimental heating process, the thermal, decomposition and endotherm of calcium carbonate resulting in an trough. Reaction equation:

$$CaCO_3 = CaO + CO_2$$

1.6DSC Atlas Summary



Comparative results description:

Figure 1.6 is a DSC atlas summary adds starch, tree bark, paper, sludge and the sludge which added Calcium oxide.Starch, tree bark, paper, sludge occur endotherm reaction at about 300 ^{o}C. Tree bark released heat most, probably due to the tree bark contains lignin, grease and other substances, the components is a little complex , when the lipid decompose and it inevitably releases a lot of heat. In the experiment, paper is used as the test sample and it also releases a lot of heat , Which may be associated with some of the chemical composition of the waste paper when producing it. Sludge curve and starch curve have little difference, which indicates that most of the ingredients contained in the sludge are starchy substances.

Conclusion

Differential scanning calorimetry is a method that can maintain the same heat flow rate and measure the temperature's difference between sample and reference, it can also quantitatively determine the thermodynamic parameters during the sludge pyrolysis process. This method has wide temperature range, high resolution, less samples, which will be widely used in municipal sludge treatment process.

Keywords: Car; Air-Conditioning System; Regionalism Design; Saving Energy

Abstract. The air-conditioning load is directly related to energy consumption of the car. Based on the characteristics and sources of the air-conditioning load of the car driven in four typical cities, this paper gives an analysis on the air-conditioning load using the steady-state heat transfer calculation method. The result indicates the regionalism design on the air-conditioning system for car is feasible and beneficial to save energy.

Introduction

As a moving object, the structure of car is very complicated, the moving direction of car is changed constantly, and the travelling environment of the car also changes, which result in more random influences on the air-conditioning load. So the car is special air conditioning object. Obviously, the air-conditioning load can be affected by different regional climate conditions, which leads in different energy consumption [1]. However, we note here that the lack of study or design on regionalism air-conditioning system [2] [3] [4] [5] [6]. For this reason the air-conditioning load of the car driven in four typical cities are calculated and analyzed by using steady-state heat transfer calculating method in this paper. We conclude the regionalism design on air conditioning system for car is available for saving energy.

Air-Conditioning Load Steady-State Heat Transfer Calculation

Heat Load Sources Analysis 1) In summer, the ambient temperature is higher than the indoor. Especially, based on the effects of solar radiation, the heat transfer through the car envelope into the indoor can lead to an increase in the indoor temperature. 2) The hot ambient air flows into the indoor through the door, window or floor of the car, which also lead to an increase in air-conditioning load. 3) The heat gain from human bodies is also the important contributor to load, which should be considered in air-conditioning load calculation. 4) The heat load of the engine room should be also considered.

Air-Conditioning System Design Parameters In accord with the design requirement of the air-conditioning system for car in China, the design parameters can be given as follows:

The outdoor air relative humidity is about 60%.The indoor air velocity should be less than 0.2m/s. The volume ventilation is about 11m^3 per man-hour. The indoor air relative humidity is about 55%, and the indoor air dry bulb temperature is 25℃. This car speed is 40 km/h, and the quantity of air leak is 18m^3/h. In this paper, June is considered as the computing date, and which can be assumed to be sunny. In addition, one driver and three passengers are considered for air conditioning load calculation. The Table 1 lists north latitudes and meteorologic parameters in four cities.

Pick Parameters of Materials Consisting of the Car Envelop Parameters of materials consisting of the car envelop are given in Table 2.

Mean Heat Transfer Coefficient Calculation

Car Envelope Heat Transfer Coefficient Calculation In this paper, the car envelope is simplified. That is, the car envelope consists of steel structure and glass window, in which the steel structure is complicated multilevel structure. And the material quality each layer of material is considered to be uniform. The heat transfer is also considered to be one-dimensional. Accordingly, the mean heat transfer coefficient of the car's side panel, front or back wall, dome, floor, window, etc., can be calculated by

$$k = \frac{1}{\frac{1}{\alpha_{in}} + \sum_{i=1}^{n} \frac{\delta_i}{\lambda_i} + \frac{1}{\alpha_{out}}} \quad \text{W/(m}^2\cdot\text{℃)} \tag{1}$$

where δ_i is the thickness of the i th material, m. λ_i is the thermal conductivity of the i th material, W/(m·℃). α_{in} and α_{out} denote, respectively, the inner and outer surface convection heat transfer of the indoor. Table 3 provides the thermal conductivity of the materials consisting of car envelope.

Table 1 North latitudes and meteorologic parameters in four cities

City	North latitude	Outdoor air dry bulb temperature (℃)
Kunming	25°01′	25.8
Wuhan	30°37′	35.2
Huhehaote	40°49′	29.9
Haerbin	45°41′	30.3

Table 2 Parameters of materials consisting of the car envelop

Envelop	Area (m^2)	Thickness (mm)	Material	Heat conductivity (W/(m·℃))
Total surface area	15.85			
Internal surface areas of the engine room	8.6			
Roof	1.51	0.7	Steel	48
Front wall	1.05	1	Steel	48
Back wall	0.52	1	Steel	48
Floor	3.17	0.7	Steel	48
Front windshield	1.1	4.8	Glass	0.754
Back windshield	0.93	3.2	Glass	0.754
Front glass doors & windows	0.54	3.5	Glass	0.754
Back glass doors & windows	0.54	3.2	Glass	0.754

Table 3 Thermal conductivity of materials consisting of the car envelope

Material	Glass	Wood	Fibreboard	Rubber	Foam plastics
Thermal conductivity (W/(m·℃))	0.754	0.14-0.29	0.23-0.34	0.16	0.04

On the basis of the value of air velocity in air conditioning zone, which is the one of the main design parameters, the convection heat transfer of the inner surface of indoor is small. The difference in temperature between the inner surface and air in indoor is denoted by Δt_b, and we get Δt_b=5℃.

Thus, $\alpha_{in} = 3.49 + 0.093\Delta t_b$ [2] $\text{W/(m}^2\cdot\text{℃)}$ (2)

Then, $\alpha_{in} = 3.49 + 0.093 \times 5 = 4$ $\text{W/(m}^2\cdot\text{℃)}$

But the convection heat transfer of the outside surface, α_{out}, varies with the running speed of the car, the air velocity and direction, etc. In this paper, the convection heat transfer of the outside surface, α_{out} is calculated from the empirical relationship, which is given by [2]

$$\alpha_{out} = 1.163\left(4 + 12\sqrt{v}\right) \quad \text{W/(m}^2\cdot\text{℃)} \tag{3}$$

in which we get v=40km/h, then, α_{out} is about 50 W/(m^2·℃).

1) For the car roof, we can give

$$\sum_{i=1}^{n}\frac{\delta_i}{\lambda_i} = \delta_{top}/\lambda_{top} + \delta_{hood}/\lambda_{hood} = 0.09\ (\text{m}^2\cdot\text{℃})/\text{W} \tag{4}$$

where we get $\delta_{top}=0.7\times10^{-3}$m, and $\delta_{hood}=6\times10^{-3}$m.

Then, k_{roof}=78W/(m^2·℃).

2) For the car's side panel, front or back wall, we can give

$$\sum_{i=1}^{n}\frac{\delta_i}{\lambda_i} = \delta_{iron}/\lambda_{iron} + \delta_{air}/\lambda_{air} + \delta_{iron}/\lambda_{iron} + \delta_{insulation}/\lambda_{insulation} = 2.7\ (\text{m}^2\cdot\text{℃})/\text{W} \tag{5}$$

where $\delta_{iron}=10^{-3}$m, and $\delta_{air}=3.2\times10^{-3}$m, which is considered as carpet

Then, k_{side}=W/(m^2·℃).

3) For the floor, we can give

$$\sum_{i=1}^{n}\frac{\delta_i}{\lambda_i} = \delta_{wood}/\lambda_{wood} + \delta_{plastics-carpet}/\lambda_{plastics-carpet} = 2.66\ (\text{m}^2\cdot\text{℃})/\text{W} \tag{6}$$

Then, k_{floor}=7W/(m^2·℃).

4) For the window

The heat transfer coefficient of window is related to the velocity of the ambient air and heat bridge dissipation from metal framework join. In this paper, based on the car can be assumed to be moving building, so we can get k_{glass}=6.38 W/(m^2·℃) from the Building Handbook.

Heat-Transfer Areas Calculation The heat-transfer areas can be determined with design drawings. In general, the heat-transfer areas can be calculated on the basis of geometric mean without respect to the influence of strengthening rib, which can be written as $A = \sqrt{A_H}\sqrt{A_B}$ m^2. And A_H and A_B denote, respectively, the total surface areas of the inside and outside of car envelope. Correspondingly, A is about 11.68m^2.

Average Heat-Transfer Coefficient Calculation The average heat-transfer coefficient can be expressed as

$$k_{cp} = \frac{\left(k_{side}A_{side} + k_{floor}A_{floor} + k_{roof}A_{roof} + k_{glass}A_{glass}\right)}{A} \quad \text{W/(m}^2\cdot\text{℃)} \tag{7}$$

Solving for k_{cp}, k_{cp} is about 3.83W/(m^2·℃)

Air Conditioning Load Calculation

The air conditioning load involves the heat transfer of the car body, the solar radiation through the glass, the fresh air load, the heat load for infiltration from the door and window of the car, and the human body heat dissipation. At steady state, the heat transfer can be given by

$$Q = kA\Delta t \quad \text{W} \tag{8}$$

where Δt is the temperature differences between the inner and outer surface of the car body, in℃. A is the surface areas of the car envelope, in m^2, and k is heat transfer coefficient, in W/(m^2·℃).

Heat Transfer of the Car Envelope Calculation The car envelope includes roof, side floor, engine room, whose heat transfer calculation is determined from

$$Q_{envelope} = k_{cp}A\left(t_{out} - t_{in}\right) \quad \text{W} \tag{9}$$

in which k_{cp} denotes the average heat transfer coefficient of the car body, and t_{out} is the outdoor air temperature. In accord with the specification in automobile air conditioning design, the indoor air conditioning design temperature t_{in} ranges from 24℃ to 28℃. In this paper, t_{in}=25℃. The symbol A

denotes the total surface areas of the car envelope, in m^2. The following Table 4 gives heat transfer of the body calculation results for the four typical cities.

Table 4 Heat transfer of the body calculation results

City		Kunming	Wuhan	Fuhehaote	Haerbin
Outdoor air dry bulb temperature	(℃)	25.8	35.2	29.9	30.3
Q_{body}	(W)	35.8	456.2	219.2	237.1

Solar Radiation through the Glass Calculation The solar radiation heat transfer through the glass is calculated

$$Q_{solar-radiation} = MA_{glass}C(\mu J_{c,\max}) \quad \text{W} \tag{10}$$

where A_{glass} is surface areas of the glass, in m^2. μ is multilayer glass correct coefficient (for standard glass, μ=1). C is the sunshade coefficient of the glass (The value of C is usually set to 1). M is areas coefficient of the glass (The value of M can be set to 0.8 for front windshield and back windshield, but for double-side glass surface, let M=0.5). And the results of the solar radiation heat transfer through the glass are listed in Table 5.

Table 5 Solar radiation heat transfer through the glass calculation results

	$J_{c,max}$ (W/m^2)				$Q_{solar-radiation}$ (W)			
City	South	East	North	West	South	East	North	West
Kunming	151	572	138	572	326.76	1237.8	298.6	1237.8
Wuhan	190	688	123	688	411.16	1488.8	266.2	1488.8
Fuhehaote	314	578	134	578	679.50	1250.8	290.0	1250.8
Haerbin	376	576	129	576	813.66	1246.5	279.2	1246.5

Fresh Air Load Calculation The fresh air load calculation can be evaluated according to the relation, as follows:

$$Q_{fresh-air} = l_o n\rho(h_o - h_i) \quad \text{W} \tag{11}$$

where n is passenger quantity(n=4). l_o is fresh air volume per man-hour. In this paper, l_o=11m^3 per man-hour, and the minimum fresh air requirement is at least 10m^3 per man-hour. ρ is the density of the air, and ρ =1.146kg/m^3. h_o is the outdoor air enthapy, in kJ/kg, which is obtained from psychrometric chart. But h_i denotes the indoor air design enthapy, and which can be also obtained via psychrometric chart. Locating the point on the psychrometric chart where the air dry temperature is 25℃, and the relative humidity is 55%, the corresponding value for h_i is about 52.5kJ/kg. The fresh air load calculation results for four typical cities are given in Table 6.

Table 6 Fresh air load calculation results for four typical regions

City		Kunming	Wuhan	Fuhehaote	Haerbin
Outdoor air dry temperature	(℃)	25.8	35.2	29.9	30.3
Outdoor air relative humidity	(%)	60	60	60	60
Outdoor air enthapy	(kJ/kg)	58	91	70	73
Fresh air load	(W)	277.3	1941.3	882.4	1033.7

Permeation Load from the Door and Window Slits of the Car Calculation The permeation load from the door and window slits of the car can be written as

$$Q_{permeation} = Ll_c\rho(t_{out} - t_{in}) \quad \text{W} \tag{12}$$

where t_{out} is the outdoor air temperature, in℃. ρ is the air density, ρ=1.146kg/m^3.The symbol l_c represents the length of the door and window silts of the car (about 12m for the door silts, and 8.5m for window silts).

The infiltration rate per meter opening joint in door and window L, m^3/h, varies with the air velocity, which can be given in accord with the dates used in civil building. In this paper, $L=4.0m^3/h$ for single steal window silts per meter, and $L=10.0m^3/h$ for door silts per meter, when the air velocity is 3m/s. The permeation load from the door and window slits of the car calculation is obtained using given data, and the calculation results for the four cities are also tabulated as

Table 7 Pereation load from the door and window silts of the car for the four cities

City	Kunming	Wuhan	Fuhehaote	Haerbin
Outdoor air dry temperature (℃)	25.8	35.2	29.9	30.3
$Q_{permeation}$ (W)	141.2	1800.3	864.9	935.5

Heat Gain From Human Bodies The heat gain from human bodies can be calculated from

$$Q_{human-body} = Q_s + qnn' \quad \text{W} \tag{13}$$

where Q_s is the heat gain from the driver (about 170W). n is the number of people (n=3). n' is clustering coefficient ($n' = 0.89$), and q is heat gain per hour from one people (q=108W).Thus the heat gain from human bodies $Q_{human-body}$ is about 458.4W.

Heat Load from Equipment and Illumination Calculation From reference[2], the heat load from equipment and illumination is

$$Q_{equipment} = (0.6 \sim 0.75)Q_1 \quad \text{W} \tag{14}$$

Thus, $Q_{equipment}$ is about 60W,when Q_1=100W from experience point.

Steady-State Total Air-Conditioning Load Calculation. At steady state, the total air conditioning load of the car can be computed from

$$Q_{total-load} = Q_{envelope} + Q_{solar-radition} + Q_{flesh-air} + Q_{permeation} + Q_{human-body} + Q_{equipment} \quad \text{W} \tag{15}$$

And the calculation results for the four cities are also shown in the following Table 8.

Table 8 Steady-state total air conditioning load of the car (W)

	Kunming	Wuhan	Fuhehaote	Haerbin
South	1299.46	5127.36	3164.4	3538.36
East	2210.5	6205	3735.7	3971.2
North	1271.3.2	4982.4	2774.9	3003.9
West	2210.5	6205	3735.7	3971.2

Analysis on the Energy-Saving

The results show that, the air-conditioning load of the car driven in Wuhan is largest, but the one in Kunming is smallest, so, which can be further compared using formula as follows:

$$\frac{Q_{total-\max} - Q_{total-\min}}{Q_{total-\min}} \quad \% \tag{16}$$

When the four directions, North, South, East and West, taken into account, the comparative results are

South: $\dfrac{5127.36 - 1299.46}{5127.36} = 74.66\%$

East: $\dfrac{6205 - 2210.5}{6205} = 64.38\%$

North: $\dfrac{4982.4 - 1271.3}{4982.4} = 74.48\%$

West: $\dfrac{6205 - 2210.5}{6205} = 64.38\%$

At last, based on above calculation results, the average of the decrease percentage of air conditioning load of car driven in Kunming can be calculated, which is about 69.48%.

Conclusion

The decrease of air conditioning load is up to 69.48%. The result shows that the regionalism design on the air-conditioning system of car has marked energy-saving effect.

Keywords： manipulator; six degrees of freedom; hydraulic system; optimization

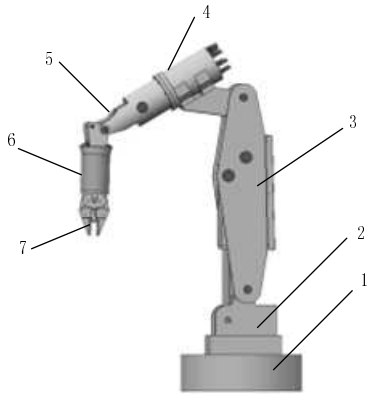
Abstract. According to the requirements for wheel hub assembly line, the structure and hydraulic system of carrying manipulator with six degrees of freedom (DOF) is designed. The working principle of the hydraulic system is analyzed. To minimize the output force of the hydraulic cylinder, a mathematical model of hydraulic cylinder output force and structural parameters is established. And then the manipulator structure is optimized based on Matlab software. The key components of the hydraulic system are selected. This research provides reference for design of similar hydraulic system of industrial robot.

Introduction

As the rapid progress of industrial automation, the manipulator is more and more widely applied in industry, especially in the environment of high temperature, high pressure, dusty and radioactive pollution [1].Most domestic material handling industries still continue the manual operation mode of production, and the problems of high labor intensity, poor working conditions, low efficiency are seriously restrict the development of the companies[2].In a wheel hub assembly line, as the hanging operation of the washing line to the spray painting line were completed by manual, the process was limited by the rhythm of the whole production line , so the labor intensity of workers was high , and the labor conditions was bad in the painting environment. It will not only reduces the labor intensity of workers, but also improves the production automation level and productivity, and ensuring product quality and safety when adopt handling robot instead of human to repeated the operation of putting hub up and down. In this paper, a carrying manipulator with six degrees of freedom (DOF) is researched, the mechanical structure and hydraulic control system are designed.

The scheme of manipulator

In order to make the manipulator system has stronger function to complete complicated tasks, the degrees of freedom are set to 6. The 3D model of the carrying manipulator is shown in figure 1. The 6 joints are all rotational joints, which are shoulder revolute joint, shoulder pitch joint, elbow pitch joint, forearm revolute joint, wrist pitch joint, and wrist revolute joint respectively. According to the power source, the drive system of the manipulator can be classified as hydraulic, pneumatic and electric. These three types can also be combined to form a composite type of drive system as needed. The main advantage of hydraulic is the big power-to-weight ratio. It means that a small drive can export a larger driving force or torque[3-4].As the manipulator mainly completes the handling work of wheel hub, and the load capacity demand is bigger, so the hydraulic driving is chosen. The forearm revolute joint of manipulator adopts swing hydraulic cylinder to driving, the shoulder and wrist revolute joints are driven by hydraulic motors, the rest joints adopt hydraulic cylinder to driving. The end of the sixth joint is designed as universal tool interface, so it can meet different material handling requirements (such as gripper, electromagnetic sucking disc).



1 - Base 2 - Shoulder 3 - Forearm 4 - Elbow 5 - Forearm 6 - Wrist 7 - Gripper

Fig. 1 The three-dimensional model of the carrying manipulator

According to the material handling requirements of wheel hub assembly line, the technical parameters of the manipulator are formulated as follows:

Degrees of freedom: 6 The maximum working radius: 2m

The end-effecter: paw, electromagnetic sucker Rated load: 60kg

The motion range of the manipulator joint is shown in table 1.

Table 1 The motion range of the manipulator joint

Joint	Actuator type	Range of motion
Shoulder rotary	Cycloid motor	360°
Shoulder pitch	Single-rod hydraulic cylinder	-30°～90°
Elbow pitch	Single-rod hydraulic cylinders	-10°～120°
Forearm rotary	Swing cylinders	270°
Wrist pitch	Single-rod hydraulic cylinders	-60°～60°
Wrist rotary	Orbital motors	360°
Paw	Single-rod hydraulic cylinders	100mm

The reliability of the manipulator is decided by the reasonable layout of manipulator hydraulic piping. Most of the traditional oil pipeline are fixed on the outside of the manipulator joints, the oil supply line is easily intertwining with rotating parts, which will damage the pipelines and also looks complicated. Therefore, the connection part of the joint adopts cavity structure, and the pipeline of the mechanical wrist adopt interior layout. This can reduce the volume and weight of the swing cylinder effectively, and can improve the reliability of the manipulator.

Hydraulic system design of the manipulator

According to the operation realization of the manipulator hydraulic control loop, it includes shoulder joint rotary loop, elbow pitch control loop, wrist and paw control loop. The principle diagram of manipulator hydraulic control system is shown in figure 2. Because the velocity of all the manipulator joints should be precisely controlled, the servo valve is used to control the manipulator. The hydraulic cylinders of the joints(shoulder pitch joint , elbow pitch joint , wrist

pitch joint) which are bearing gravity load are equipped with a one-way liquid control valve with better sealing performance. When the system unload, the cylinder will be locked without moving, so that the joint realize the self-locking function. The paw joint adapts the two-way lock loop of the hydraulic one-way valve, so that the paw can lock the current location reliably. In order to meet the material grabbing requirements, a pressure reducing valve 15 is fixed on the hydraulic to adjust the clamping force. To ensure the stability of the wrist rotation joint movement, a back pressure valve 13 is installed on the oil return line of motor so as to reduce the starting impulse.

12. Pilot operated check valve 13 . Backpressure valve 14. Solenoid valve 15. Valve
Fig. 2 The hydraulic system schematic of manipulator

In order to keep the system oil clean , a high pressure cleaner is fixed at the outlet of pump and an oil filter is fixed at the inlet of tank. When the oil circuit is clogged by impurities, the pressure relay of oil filter is working, the system stops running and alarms to ensure the work reliability.

Important components design of hydraulic system

Calculation design of hydraulic cylinder. Because of the limited space, the article take the wrist pitch joint hydraulic cylinder as an example to design and analysis, and the design method of the other hydraulic cylinders are in the same.

The force analysis of hydraulic cylinder. Wrist pitch joint is an oscillating guide bar mechanism and its force analysis is shown in figure 3. Point A is connection point of the pin and shaft at wrist joint, B is the fixed point of hydraulic cylinder, O is the fixed point of wrist rotating shaft, a is the length of the rocker, b is the length of the frame. Hydraulic cylinder is the active part and does reciprocating motion, the connecting rod OA is drove by hydraulic cylinder to complete the pitching motion of wrist joint. ϕ is the angle between the initial position of the bar($\theta = 0$)and the frame, the force of the hydraulic cylinder is related to a, b, ϕ . G=(60+21)×9.8 = 793.8N , $-60^\circ \le \theta \le 60^\circ$. In the traditional design process, the maximum output force of hydraulic cylinder is considered at the point that the manipulator is in horizontal straight state. This assumption ignored the force transfer performance among the connecting bars, the calculation did not conform the real stress state of the mechanism. In order to make the hydraulic cylinder has the smallest load(output force), the force equation of the mechanism is established and the parameters is also optimized.

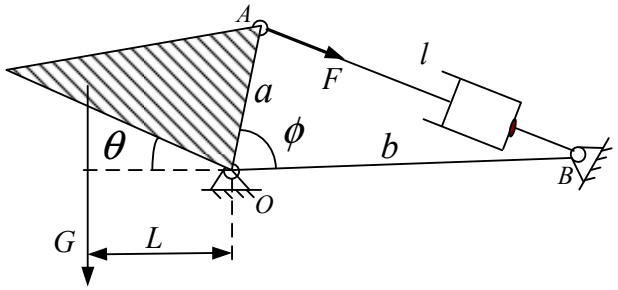

Fig. 3 The force diagram of wrist joint

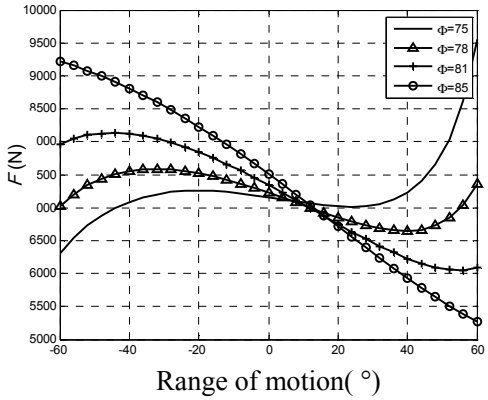

Fig. 4 The effect of the value ϕ on the load force

The force balance equation according to O point can be gotten as follows

$$\mathrm{G}\times L\times\cos\theta = F\times\frac{ab\sin(\phi-\theta)}{l} \tag{1}$$

Where : G - gravity equivalent load , N; L - the effectiveness lever of arms , L=0.461m;
θ - Wrist pitch angle , °; a, b - Rod length , m;

From equation (1) , the output force F expression of cylinder can be obtained:

$$F=\frac{G\times L\times\cos\theta\times l}{ab\sin(\phi-\theta)} \tag{2}$$

Obviously, the output force F is not only related with the structure parameters *a, b*, but also associated with the initial position. In order to minimize $F_{\max}$, different a, b, ϕ are chosen, the mechanical structure parameters are determined through optimizing design by Matlab software simulation. Considering the workspace requirements of the manipulator, set up the range of the parameter, then the driving force F can be calculated, as is shown in Figure 4, 5, 6.

(1) Setting a=55mm, b=170 mm, changing the value of ϕ. The relationship between F and the wrist pitch angle is shown in figure 4. From the figure, it can be seen that ϕ has a significant effect on F, which is nonlinear, when ϕ=78 °, the average value of output force is the smallest.

(2) Setting a=55mm, ϕ=78 °, changing the value of b . The relationship between the load capacity and the wrist pitch angle is shown in figure 5. From the figure, it can be seen that b has little effect on F, the curve of output force is symmetry about $\theta=0$, this means the force of hydraulic cylinder in the extended and retracted process are the same.

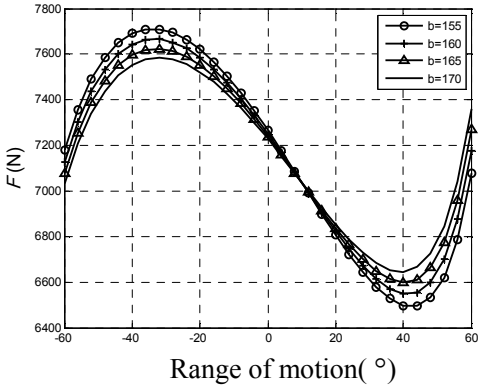

Fig. 5 The effect of the value *b* on the load force

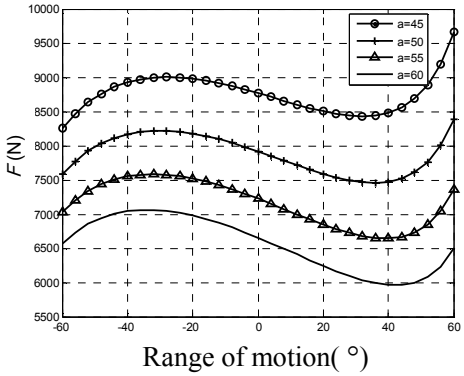

Fig. 6 The effect of the value *a* on the load force

(3) Setting b=170 mm, ϕ=78°, changing the value of a. The relationship between F and the wrist pitch angle is shown in figure 6. It can be seen that the effect of a to F is monotone increasing.

Combined with the calculation results and considering the overall size requirement of the manipulator, setting a=55mm, b=170mm, ϕ=78 °. With the parameters, the needed load force of the hydraulic cylinder is smaller, that is, the whole forced condition of the manipulator is good. According to the above, $F_{\max}$ =7530 N, taking it into the correlation formula, the structural parameters of hydraulic cylinder can be gotten: D=34mm, d=24mm.

The maximum output force checking of hydraulic cylinders. The maximum thrust of the Hydraulic cylinder is as follows

$$F_t = \frac{\pi}{4} D^2 P_1 = 16085\text{N} \quad (3)$$

Where, P_1 is the highest working pressure in the working process of hydraulic actuator, $P_1 = 16\text{MPa}$.

The maximum pulling force of hydraulic cylinder is as follows

$$F_t = \frac{\pi}{4}\left(D^2 - d^2\right) P_1 = 8482.3\text{N} \quad (4)$$

The above results can meet the load requirements.

The calculation of hydraulic cylinder stroke. The displacement formula of Hydraulic cylinder piston is as follows:

$$ll = l - l_0 = \sqrt{a^2 + b^2 - 2ab\cos(\phi + \theta)} - \sqrt{a^2 + b^2 - 2ab\cos(\phi)} \quad (5)$$

Where, l_0 is the length of hydraulic cylinder when it is in median.

$$l_{\max} = \sqrt{a^2 + b^2 - 2ab\cos 140} = 225\text{mm}$$

$$l_{\min} = \sqrt{a^2 + b^2 - 2ab\cos 20} = 130\text{mm}$$

The Stroke of Hydraulic cylinder can be gotten : $S = l_{\max} - l_{\min} = 95\text{mm}$.

Conclusion

The structure and hydraulic control system of carrying manipulator with 6-DOF has been designed in this paper. The hydraulic system has completed the servo control of the manipulator, and can meet the carrying requirements of automobile hub. Based on this research, the manipulator can be applied on material handling and stacking in the other industry, such as machinery manufacturing, metallurgy, building materials, with change of the end effector

Keywords: asynchronous motor, SPWM, aerostatic guideway, vector control

Abstract: The asynchronous motor is converted to a model similar to DC motor to control through coordinate transformation, and adopt SPWM inverter circuit, the motor runs with load implements ideal speed and steady operation, providing appropriate speed for aerostatic guide way. Realize simulation of asynchronous motor variable frequency speed regulation system by simulink.

0.Introduction

In recent years, domestic demand for precision and ultra-precision machining and measuring equipment is increasing, Ultra-precision machine tools is the fundamental condition to achieve primary ultra-precision machining, and rail component is critical among ultra-precision machine parts[1]. Since air has low viscosity, small vibration, thermal stability and does not pollute the environment etc. Small changes in load ultra-precision machine tools and measuring machines and other precision machinery usually adapt aerostatic guide way, which is widely used in ultra-precision machining[2], its movement accuracy reaches micron level. That motor provides a stable output speed is an important guarantee to achieve its precise movement.

Compared with DC motor, AC motor is more simple, rugged, reliable, low cost, easy maintenance etc, which is widely used in industrial areas. This paper adapts vector control method, and use SPWM to control induction motor speed in simulink. With given load, obtain ideal output speed. Additionally it has used a three-phase rectifier circuit to change AC into DC power supply.

1.Mathematical model of induction motor

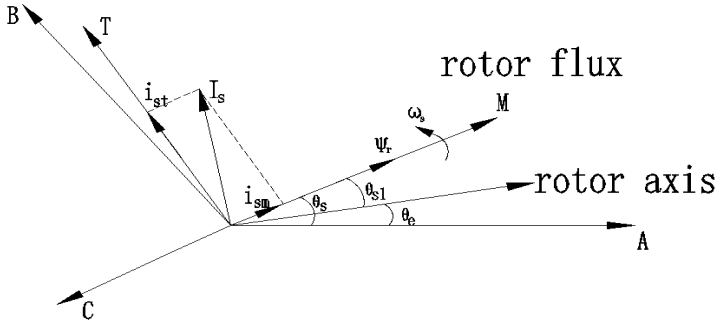

Fig1. Rotor field orientation M-T coordinate system and static *abc* coordinate system

The basic idea of vector control is to define i_m as current component, obtain two-phase AC control volume i_α， i_β by vector rotating coordinate transformation, obtain three-phase AC control volume i_a， i_b， i_c by two-phase to three-phase coordinate transformation external the motor[3].

In figure 1, i_{st} and i_{sm} are stator current components, ψ_r is Rotor flux, in M-T coordinates of Rotor magnetic oriented field, T-axis coincides with rotor flux Axis, thus flux component *m* equals rotor flux amplitude ,*t* component equals 0, mechanical speed ω_r is state variables, u_{st} on variable *t* and u_{sm} on variable *m* of Stator voltage vector are both controlled quantities.

Torque equation in M-T rotate axis and Equation of stator current component ψ_r in M-T axis:

$$T_e = n_p L_{md}(i_{st} i_{rm} - i_{sm} i_{rt}) \tag{1}$$

$$\Psi_{rt} = 0 = L_{md} i_{st} + L_{rd} i_{rt} \tag{2}$$

From (1) and (2): $$T_e = n_p \frac{L_m}{L_r} i_{sm} \psi_r \tag{3}$$

Obtain voltage equation from rotor-oriented three-phase asynchronous motor mathematical model:

$$\begin{bmatrix} u_{sm} \\ u_{st} \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} R_S + PL_{sd} & -\omega_S L_{sd} & PL_{md} & -\omega_S L_{md} \\ \omega_S L_{sd} & R_S + PL_{sd} & \omega_S L_{md} & PL_{md} \\ PL_{md} & 0 & R_r + PL_{rd} & 0 \\ \Delta\omega L_{md} & 0 & \Delta\omega L_{rd} & R_r \end{bmatrix} \begin{bmatrix} i_{sm} \\ i_{st} \\ i_{rm} \\ i_{rt} \end{bmatrix} \tag{4}$$

It can be obtained by the third line of equation (4) as:

$$i_{rm} = -\frac{P\Psi_r}{R_r} \tag{5}$$

Besides, $$\Psi_r = L_{md} i_{sm} + L_{rd} i_{rm} \tag{6}$$

By equation (5) and (6),we have

$$\Psi_r = \frac{L_{md}}{T_r + 1} i_{sm} \text{ ; where } T_r = \frac{L_{rd}}{R_r} \tag{7}$$

Equation (8) and (4) show that flux determined by i_{sm}, torque determined by i_{st} respectively [4].which realize a decoupling of torque and flux.

2.Coordinate transformation

In the case of produce the same rotating magnetic field, three-phase symmetrical sinusoidal alternating current can be converted into two-phase symmetrical sinusoidal AC. Two- phase sinusoidal alternating current can be converted into a two-phase alternating current rotation. Expression is as follow[5]:

$$i_{MT} = C_{3/2} i_{abc} = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\varphi & \sin\varphi & 0 \\ -\sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} i_{abc} = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\varphi & \cos(\varphi - 120) & \cos(\varphi + 120) \\ -\sin\varphi & -\sin(\varphi - 120) & -\sin(\varphi + 120) \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} i_{abc} \tag{8}$$

3 System Simulation

3.1 System Simulation Model

Motor parameters: rated power: 1.5kw, rated speed: 1600r/min, n_p=2, L_s=0.071H, L_r=0.071H, L_m=0.069H, J=0.02kgm^2, R_s=0.435Ω, R_r=0.816Ω, default speed: 1400r/min.

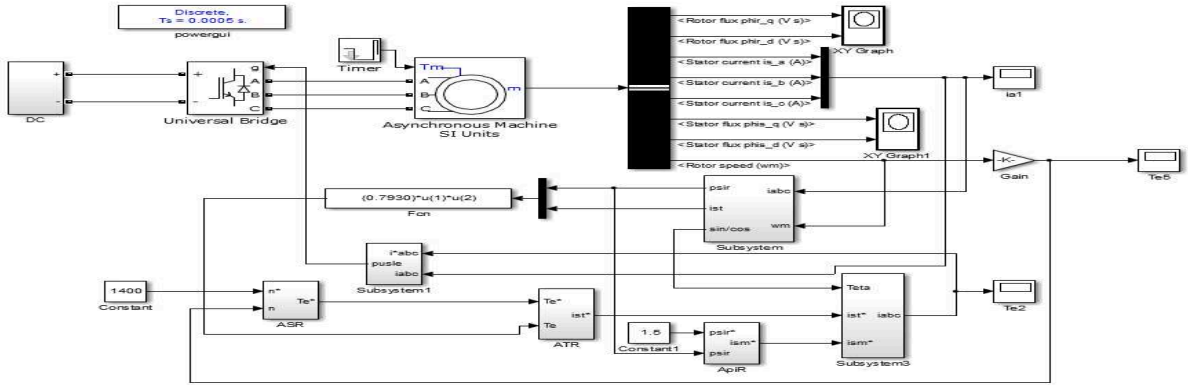

Fig2.System simulation

3.2 flux observer module

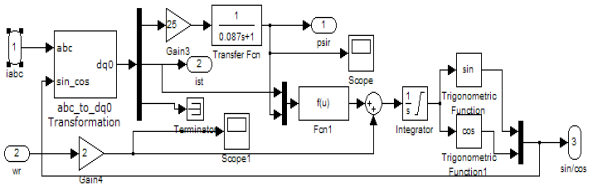

Fig3. Flux observe module

According to field-oriented equation, we have:

$$\Psi_r^*=\frac{L_{md}}{T_r n_p+1} i_{sm}^* \tag{9}$$

$$\Delta\omega^*=\frac{i_{st}^* L_{md}}{T_r \Psi_r^*} \tag{10}$$

$$\Delta\omega^* + \omega = \omega_S \tag{11}$$

$$\int (\Delta\omega^* + \omega)\mathrm{d}t = \varphi_S \tag{12}$$

3.3 Current hysteresis control module

The module is composed of three hysteresis controllers and three logical operators, its input quantities are three-phase current , actual measured values and its output quantities are 6-channel PWM inverter control signal, by controlling each bridge arm on-off time to regulate average current[6] to control motor speed. According to changes in input signal, relay hops between logic 0 and 1 to control on and off of diodes in full bridge, producing sinusoidal phase current.

Torque and flux modules adapt PI regulator, besides adapt PID regulator ways to control speed.

4 Simulation results and analysis

4.1 AC to DC circuit output voltage image

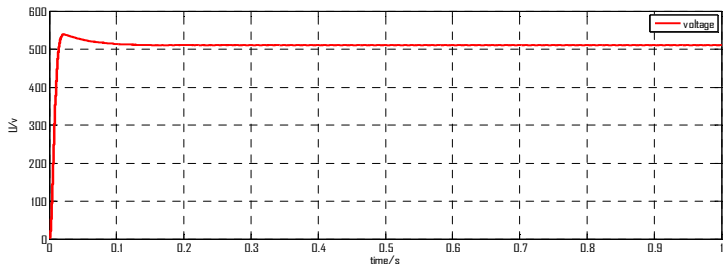

Fig. 4. Voltage curve

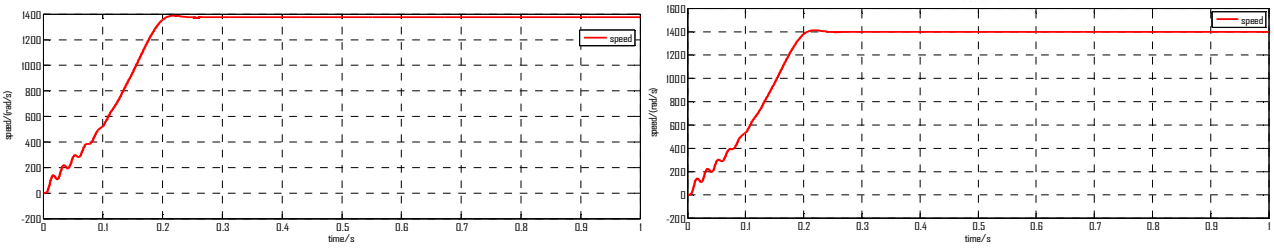
The figure shows voltage value stabilized at 510V at 0.05s after the start, meeting requirement.



a) no-load speed curve b) load speed curve

Fig5. Asynchronous motor speed curve

4.2 motor speed curve

As Figure 5a) shows, from 0s to 0.1s, speed undulates because of unsteady current. It reaches 1400r/min quickly at 0.2s and runs stably afterwards. As figure 5b) shows, with 5Nm load, speed slows down only a little after steady. Because torque is combined with active torque caused by supply voltage, offset torque caused by sensor voltages and torque caused by load, they keep balance, once increase the load, it will reduce speed to keep balance. The design results of smooth running closes to 1400r/min after loaded, meeting requirements of aerostatic guideway running.

5. Conclusion

By simulation, we can get a fast speed response curve, which is easier to realize than M function. The system function is complete, which can simulate the actual system realistically. Meanwhile we can obtain the following conclusions:

1. A steady DC power can be obtained through three-phase power by rectifier to achieve an inverter to adjust the motor speed.
2. Induction motors can be converted into the similar DC motor to control by the coordinate transformation.
3. Rotor flux and torque can be achieved by calculating the corresponding decoupling, easy individually controlled and implement.

This simulation system provides a reference for the design of actual asynchronous motor speed and the accurate running of precision air hydrostatic guideway

Keywords: Lean management techniques, Value stream mapping, Current state map, Future state map, Waste, Packages flow, Hub centers, Automation process, Cellular layout

Abstract. CTC Express is the leading domestic company in delivery service and wants to improve their business efficiency by establishing lean management in the shop floor activities. Lean management is generally adopted by the manufacturing industries as a significant technique to reduce waste and operation costs. This paper investigates the continuous improvement through value stream mapping, begins with describing the current situation and proposes the future condition. Several improvements were implemented in the company such as the transformation of automation process, better result in visual control and standardization processes. The new proposed system has shown being able to reduce the works of loading/unloading and in the same time to increase the performance of material handling in each cycle time.

Introduction

Tight competition among delivering service companies forces the companies to rethink about the performance improvement in their business processes. In the process of improving the performance, companies attempt to construct new approaches to increase the quality of their business activities and to concurrently reduce the waste processes. In order to fulfill the improvement activities, lean management techniques are generally used as a central knowledge for many companies to develop their continuous improvement environment [1].

Lean manufacturing was first popularized by Toyota Company with the name of "Toyota Production System" [2]. It was then introduced to the academia under the new term of "Lean Manufacturing" or "Lean Thinking" [3]. The purpose of Lean Manufacturing is to eliminate waste, where waste means everything in the processes that will add cost without adding value.

This study explored the principles of lean manufacturing for improving the logistics process efficiency of the CTC Express, a leading delivery service company in Taiwan. This logistic process is focus on a central hub warehouse, where the package-flow could come from branch-warehouse and the customer at the central hub city.

Empirical follow up study shows that the overall performance after the implementation of the automation system improved the company's efficiency by 25% without the need for overtime labor hours.

Literature Review

The related literature review is made on the area of lean in the Logistics Industry. The benefits of lean ideology successfully breakthrough in several research areas [4], most researches tried to improve algorithms for developing alternative and efficient initial layout. A significant layout lean principle came from ALCAST Pte Ltd Manufacturing [5]. It mentioned the benefits of using the cellular layout to improve the manufacturing process with several additional lean principles, the result could detect the several non-value adding activities and considered as an important source for the improvement process.

Value Stream Mapping (VSM) is considered as an important tool on the implementation of lean principles. One example of the VSM use performed by SMC Company [6], the SMC Company uses the VSM and Kaizen tools to optimize the assembly line. Another good example of the VSM applied by ABS Company [7], the research found out the benefits of VSM combined with lean tools and justified it through statistical approach. The example of VSM implementation in the service area performed by health sector [8], it has proved that VSM could eliminate the non-value added waste in their procurement facility.

The automation process has been realized by researchers for period of time as an important part in the lean principles. In one of the research [9], the idea of automation process was investigated in the shop-floor data-capture to enable the automation in the manufacturing process. Automatic Identification and Data Capture (AIDC) was proposed to improve the inventory performance. Another automation process using belt conveyor in lean area performed in the manufacturing [10], the research design the optimal conveying system in order to implement the lean principles.

Shop Floor Improvement

Even as the largest B2B/B2B2C logistic provider in Taiwan, the CTC Company still operates solely based on manual power. Four main procedures that would have to be done before packages are delivered out of the hub center: unloading, barcodes scanning, verifying, and uploading.

The *current state map* and *future state map* were derived using the lean principles [11]. The two maps provide valuable criteria to find out the waste jobs and to re-arrange the package flow. Automated conveyor systems were introduced to improve the performance of package flow.

The conveyor would allow the sorting procedure and the verifying procedure be eliminated. The future value stream of the company would be flowing from unloading procedure directly to the palleting and uploading procedure. It has decreased the workers' workload to walking and in the same time eliminating the vulnerable condition of injury.

In addition, the system is designed to ensure that the information obtained at the work flow could be output to the computer which could then be integrated with the information system.

The intelligent weighting cells and barcode scanning equipment were integrated in the system so that every package would be weighed to increase the company's profitability without adding work load on the workers. The completed novel system shows being able to handle one truckload of packages in ten minutes, compared to the currently procedure, which needs sixteen minutes, indicating a 63% capacity increase.

Takt Time Analysis

To measure the effect of increasing performance, *Takt Time* analysis is performed in this study. Takt Time is a formulation in lean principles to define the rate of a process required to produce in order to fulfill the customer demand, the formula can be seen in the equation as follow,

$$TaktTime = \frac{Time\ Available\ during\ the\ Period}{Customer\ Demand\ in\ Period} \quad (1)$$

The Takt Time is used to know the rate in which a process needs to produce to fulfill the customer demand; if the product is done faster than Takt time then it will become *over production* and if it is lower than Takt Time then the outcome has *downstream shortages* that need overtime to fulfill the needs [12].

Two shifts working practice is normally employed in CTC which indicates 14 hours (50400 second) of work. The established package processed numbered at 198,000 every day. Therefore the standard Takt Time equals to 0.25second/package. However, the Takt Time generated in the current system is 0.28 second/package. An encouraging result of 0.21second/package was obtained from the trial-run of the proposed system.

Statistical T-Test Analysis

To measure the effect of increasing performance, T-Test analysis is performed in this study. Several parameter comparisons were used between Current State Map and Future State Map which comprise of Total Time; Value Added Time; performance of VSM; Performance of Savings; Performance of Gap Time.

The result of T-Test analysis by using Minitab Software is shown on Table 1. The result of T-Test analysis prove the significant different between the Future State Map and Current State Map with the T-Value of 1.53. Statistically, Future State Map has greater performance with the P-value of 0.093 in the confidence level of 90%. It is accepted that the proposed automated system is causing significant improvement.

Table 1. T-Test Result by Using Minitab Software

	n	Mean	StDev	SE Mean	T-Value
Future System	6	48.4	53.3	21.8	1.53
Current System	6	38.2	37.6	15.4	

Summary

Lean techniques are widely applied under manufacturing context; they are being applied to the delivering business successfully in this research. Improved efficiency with less labor hours is observed. However, takt time and labor hours are the only factors considered as performance indicators in this research. It is suggested to the future researches that more lean limitations and indicators to be used to evaluate the implementation of Lean techniques in the delivering industry for further in depth understanding of the effect of Lean.

Research on Direct Torque Control adaptive Fuzzy Neural Network Controller of Permanent Magnet Synchronous Motor

Chaofan Lu[1, a], Hongbin Yu[1,b]

[1]School of Mechanical Engineering, Tianjin Polytechnic University,Tianjin,300380, China

[a]luchaofan_lz@163.com, [b]hbyu@yahoo.cn

Keywords: permanent magnet synchronous motor (PMSM); direct torque control (DTC); fuzzy neural network (FNN)

Abstract. Has the advantages of quick response of PMSM using the method of DTC, but will make the high torque and big magnetic flux linkage ripples. In order to solve this problem, using the fuzzy neural network hybrid system to replace the traditional hysteresis controller, Strong learning ability and fuzzy logic in handling uncertain information has the adaptive ability of neural network, the fuzzy neural network hybrid system to produce the expected voltage vector, the speed of a smooth transition of permanent magnet synchronous motor. The proposed method is validated by simulation under external disturbances in motor is very effective to reduce the ripple of torque and flux, the speed of the fast response and smooth transition.

Introduction

PMSM is widely used and the key of PMSM is how control it. Direct torque control method is proposed in recent years, it can make the PMSM has fast response, but the flux and torque fluctuations are larger. In this thesis presents a method combined with control of permanent magnet synchronous motor direct torque fuzzy neural network hybrid system. This thesis introduces the principle of fuzzy neural network hybrid system and direct torque control, modeling and simulation by MATLAB/SIMULINK, the simulation verify the effectiveness of the theory.

The Principle of Fuzzy Neural Network Hybrid System

At present, the network structure and learning algorithm of fuzzy neural network inference based on Mamdani, it is the most widely used. It is based on Neural Network memory the fuzzy control rules. According to the operation steps of hierarchical structure of fuzzy logic system, then by using the neural network learning algorithm do not change the fuzzy logic system[6~9].

The input vector is $x=[x_1,x_2,\ldots,x_n]^{\mathrm{T}}$, for each component x_i is fuzzy language variables, set $\mathrm{T}(x_i)=\{A_i^1,A_i^2,\cdots,\mathrm{A}_i^m\},i=1,2,\cdots,n$,among them $A_i^j(j=1,2,\cdots,m_i)$ is x_i the first j language variable value, it is defined in the domain U_i of a fuzzy set, The membership function of the corresponding is $\mu_{A_i^j}(x_i)$, （ $i=1,2,\cdots,n;j=1,2,\cdots,m_i$ ） . Output y is Fuzzy linguistic variables $\mathrm{T}(y)=\{B^1,B^2,\cdots B^{m_y}\}$, among them $B^j(j=1,2,\cdots m_y)$ is y the first j language variable value, it is defined in the domain U_y of a fuzzy set, the membership function of the corresponding is $\mu_{B^j}(y)$.

A description of the relation between input and output of fuzzy rules： if x_1 is A_1^i and x_2 is A_2^i and $\cdots x_n$ is A_n^i, then y is B^i , among them $i=1,2,\cdots,m$, m express the total number of rules , $m\le m_1m_2\cdots m_n$.

According to the fuzzy model of fuzzy system constructed above, such as fuzzy neural hybrid system is shown in Figure 1.

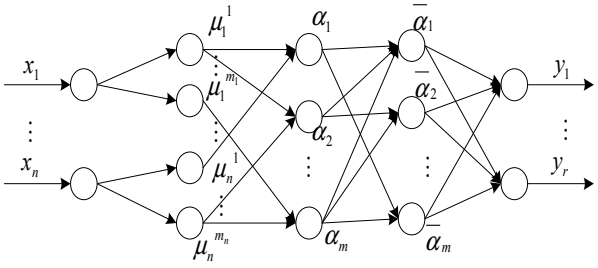

Fig.1 Structure fuzzy neural hybrid system

This structure is divided into five layers. Among them, the first layer is the input layer; the second layer of every node is the role of computing input component, representing a linguistic variable value. The formation of a fuzzy set, to construct the membership function μ_i^j , then $\mu_i^j = \mu_{A_i^j}(x_i)$, $i = 1,2,\cdots n; j = 1,2,\cdots m_1,$ among them m_1 is x_1 the fuzzy partition, n is The number of input variables; The third layer is used to match the premise part of fuzzy rules; each node represents a fuzzy rule, fitness degree of every rule, $\alpha_i = \min\{\mu_1^{i_1}, \mu_2^{i_2}, \cdots, \mu_n^{i_n}\}$ Among them $i_1 \in \{1,2,\cdots,m_1\}; i_2 \in \{1,2,\cdots m_2\}, \cdots, i_n \in \{1,2,\cdots,m_n\}, j = 1,2,\cdots,m, m = \sum_{i=1}^{n} m_i$ .Principle of the fourth layer and the third layer is the same.Objective is calculated to achieve normalization, $\overline{\alpha}_j = \dfrac{\alpha_j}{\sum_{j=1}^{m} \alpha_j}, j = 1,2,\cdots m$ .The right of the layer is the output layer, the purpose is clear to calculate fuzzy, $y_i = \sum_{I=1}^{M} w_{ij}\overline{\alpha_j} = \dfrac{\sum_{i=1}^{M} w_{ij}[\mu_{B^{ij}}(w_{ij})]}{\sum_{i=1}^{M}[\mu_{B^{IJ}}(w_{ij})]}, i = 1,2,\cdots r$,Among them w_{ij} is the j language value Membership function the center value, written in vector form: $y = W\overline{\alpha}$,

Among them, $y = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_r \end{bmatrix}, W = \begin{bmatrix} w_{11} & w_{12} & \cdots & w_{1m} \\ w_{21} & w_{22} & \cdots & w_{2m} \\ \vdots & & \ddots & \vdots \\ w_{r1} & w_{r2} & \cdots & w_{rm} \end{bmatrix}, \overline{\alpha} = \begin{bmatrix} \overline{\alpha_1} \\ \overline{\alpha_2} \\ \vdots \\ \overline{\alpha_m} \end{bmatrix}$.

It is proved that fuzzy neural network has the ability of universal approximation property [6]. Fuzzy neural network has the universal approximation property and learning algorithm, Fuzzy neural network controller as shown in figure 2. $w_r(n)$ is the current moment motor actual speed, $w^*{}_r(n)$ is The current moment motor speed setting, $w_r(n-1)$ is the actual motor speed the former cycle, $w_r(n-2)$ is the actual speed of the motor of two former cycle , $i_q(n)$ is the present moment the stator current, $i_q(n-1)$ The stator current the former cycle, $\Delta i^*{}_q(n)$ is set value, $\Delta i_q(n)$ is the stator current domain value5%.

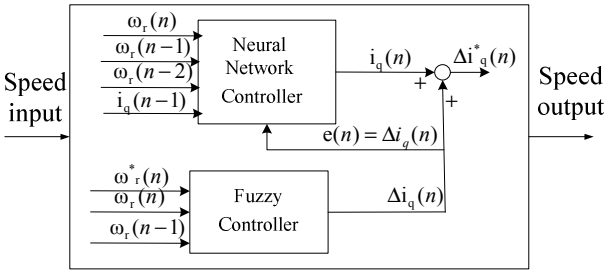

Fig.2 Fuzzy neural network controller

When motor running, the error value of each sampling period transmission to the fuzzy controller, if the actual speed of the motor is equal to the set value, fuzzy controller error value is zero, to calculate the network weights and threshold according to the neural network controller before sampling. If not equal to the set value, continue to adjust.

The Principle of Direct Torque Control

ψ_s is the stator magnetic flux linkage, ψ_r is the rotor magnetic flux linkage, PMSM rotor magnetic flux linkage is produced by permanent magnet, so ψ_r is constant. T is Electromagnetic torque, θ is ψ_s and ψ_r Angle [1]. Figure 3 is a permanent magnet synchronous motor M – T reference coordinate system.

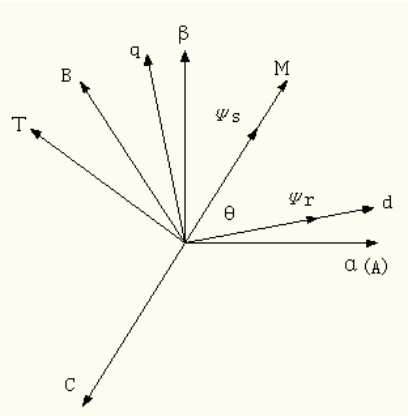

Fig. 3 M – T reference coordinate system

From Fig3 Can be drawn in permanent magnet synchronous motors M – T reference coordinate system Torque equation [1]:

$$T = \frac{3p|\psi_s|}{4L_dL_q}[2\psi_r L_q \sin(\theta) - |\psi_s|(L_q - L_d)\sin(2\theta)] \quad (1)$$

if ψ_s is constant, then T control θ [2].

Ignoring the effect of stator resistance R, According to the $\psi_s = \int (V_S - Ri_s)dt$ known, ψ_s to V_s applied in permanent magnet synchronous motor voltage vector direction adjustment. The switch tube has 8 working state combination, Inverter produce 8 voltage vector, including six non-zero voltage vector $V_1 - V_6$ and Two the zero vector V_0 and V_7. Voltage vector plane is divided into six areas, as shown in Figure 4 (a) shows, ψ_s in different regions, you can select different voltage vector. Because the choice of voltage vector relationship only with the ψ_s region, direct torque control the core is that According to the different voltage vector V_s adjustment ψ_s size come true θ change, in order to control T [2].

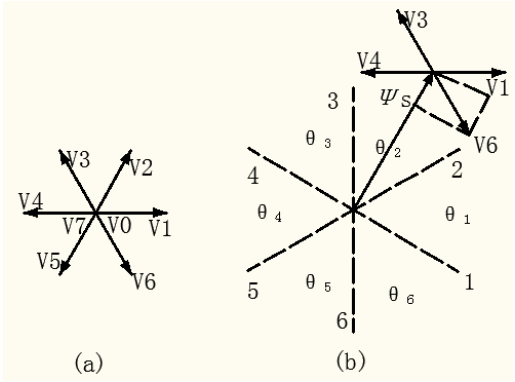

Fig. 4 Voltage space vector diagram

In order to realize Reduce The torque and magnetic flux linkage pulsation We must as soon as possible to change between the stator and rotor magnetic flux linkage θ, By selecting the appropriate space voltage vectors, ψ_s constantly advance and retreat, through the instantaneous change θ, control torque T, reducing pulsation of torque. The vertical and radial of space voltage vector decomposition of two directions in accordance with ψ_s, so the vertical component of the voltage vector can change the size of the electromagnetic torque, the radial component of the voltage vector can change the size of the stator magnetic flux linkage, Figure 4 (b) is the decomposition of with V_2 as example.

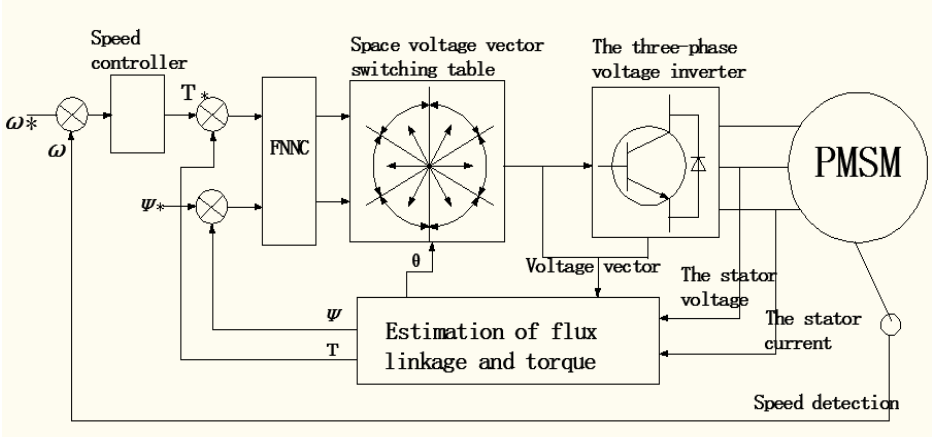

Fig. 5 The DTC system principle diagram of PMSM

The principle of PMSM of DTC is that compares between actual speed and the given speed of PMSM, the error between the two as input speed controller, speed controller output given torque. Three phase current and phase of the measured stator voltage delivery to the magnetic flux linkage and torque estimation process, The output torque value compared with the given torque speed controller output, the error input them into FNN control system. The flux values compared with the stator flux given value, error input to the FNN control system. The two output FNN control system and the stator flux linkage region judgment value as input of switching table, draw a set of control pulse, Control of three-phase voltage inverter switching, and control of PMSM.

Through FNN hybrid system generate the expected voltage vector, according to a sampling period of flux linkage and torque deviation determine voltage vector expected next sampling period. It is determined by the switching two adjacent non-zero voltage vector [3]. To achieve smooth flux trajectory and reduced torque pulsation [10~12]. Fig. 5 is the DTC system principle diagram of PMSM.

4. Simulation of DTC using FNN hybrid system

The PMSM parameter is: rated power $P_N = 3kW$, rated voltage $U_N = 380V$, magnetic pole $P = 2$, the stator resistance $R_S = 0.518\Omega$, direct axis inductance $L_d = 0.9(mH)$, quadrature axis inductance $L_q = 0.9(mH)$, $\psi_f = 0.1252(Wb)$, $\psi^* = 0.1252Wb$.

Input conditions: $T = 0N \cdot m \rightarrow 10N \cdot m \rightarrow 0N \cdot m \rightarrow 10N \cdot m$, $\omega^* = 1500r/\min$, the simulation results as shown in Fig. 6:

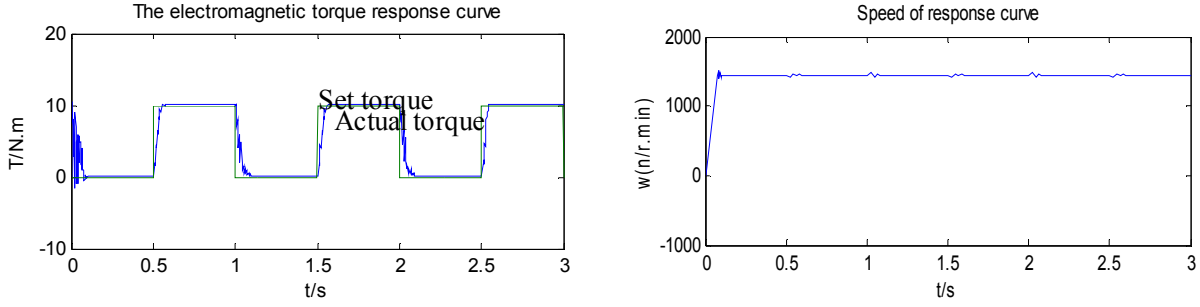

Fig. 6 The electromagnetic torque response curve and speed of response curve

From the Fig. 6 we know: The actual torque value well track torque setting and faster into a stable state to reduce torque ripple. Speed on the torque step jumping nodes only has small fluctuation, and soon the stability to the set speed. To demonstrate the effectiveness of DTC control of speed improvement of PMSM by use of FNN.

Abstract. The series and parallel energy storage system based on super capacitors can quickly adjust a wide range of active and reactive power in two directions, which is a new way to improve the stability and power quality of new energy power generation system. In this paper, double converters structure is used to achieve the series and parallel compensation effect and their control strategies according to Instantaneous Power Theory. It is simulated in PSCAD that series and parallel energy storage system of super capacitor contribute to the impact on wind turbines power as environment conditions change. Simulation results show that the energy storage system can greatly improve the stability and power quality of grid-connected wind turbines.

Introduction

In recent years, it's a power industry hotspot to utilize energy storage systems for solving the problem of new energy generation system power fluctuations and power quality. With the excellent characteristics [1][2], super capacitors is gaining favor in many scholars. Currently, super capacitor energy storage devices are mostly connected to the grid in parallel [3]. If the double converters structure is adopted in the energy storage system to achieve series and parallel compensation active and reactive power can quickly adjust in two directions and a wide range. By this way, the series and parallel energy storage system of super capacitors is able to maintain the power stability and improve power quality of new energy power generation.

Principle of the series and parallel energy storage system

The energy storage system is installed in the point where the new energy generation system is connected to grid. The structure of the series and parallel energy storage system of super capacitors is shown in Figure 1.

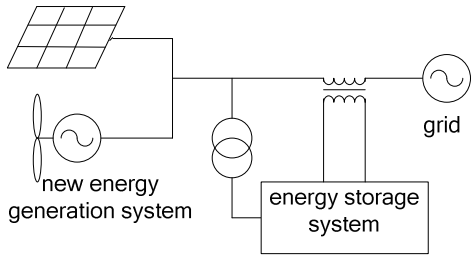

Fig.1 Structure of the series and parallel energy storage system of super capacitors

Parallel inverter of the energy storage system injects current to the system. Through the parallel compensation device, it's easily to injected or absorbed active and reactive power from the system. Therefore, parallel compensation can control the active and reactive power balance of power system. Series inverter of the energy storage system can inject a voltage component changing continuously and voltage fluctuation and voltage sag is easily offset through the series compensation from the energy storage system. Therefore, the series compensation can guarantee stability of the supply voltage [4-6].

Energy storage system of super capacitors

The energy storage system of super capacitors need for DC / DC converter and it control system helping super capacitor charging and discharging [7]. The circuit topology of super capacitor energy storage system is shown in Figure 2, which consists of bi-directional DC / DC converter and super capacitors.

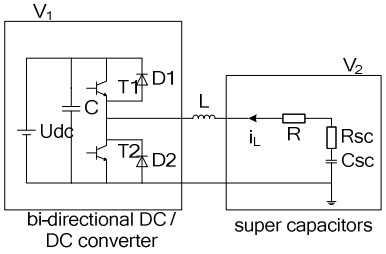

Fig.2 Super capacitor energy storage system circuit topology

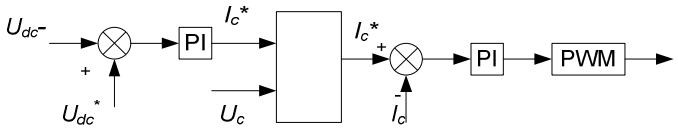

Fig.3 Converter control diagram

The control target of DC/DC converter [8] is not only to maintain a constant high DC voltage of energy storage system but also to meet the super capacitor power limit. Converter control diagram is shown in Figure 3.

In the diagram, U_{dc} stands for measurements value of the DC high voltage; U_{dc}* stands for DC high voltage reference value, determined by the charging and discharging state of super capacitors. According to U_c, the actual voltage of the super capacitor, the current reference value is limited in a certain range. Then based on the current reference value I_c* and the current flowing through super capacitor I_c , control signal can be obtained.

Control strategy of the parallel inverter

The circuit topology of parallel storage system is shown in Figure 4, the connected-grid voltage of new energy power is U_{wa}, U_{wb} and U_{wc}, connected-grid current is I_{wa}, I_{wb} and I_{wc}, and output power is P_w and Q_w. Filter capacitor in parallel storage systems is C_{pf}, the power flowing into the filter capacitor is P_b and Q_b, and current is I_{ba}, I_{bb} and I_{bc}. The parallel transformer is T_p, and the filter inductor is L_{pf}, the current flowing into filter inductor is I_{bpa}, I_{bpb} and I_{bpc}. The DC voltage rectified by converter is U_{dc}, and the capacitor of DC side is C_{dc}. DC side is connected to super capacitor energy storage module.

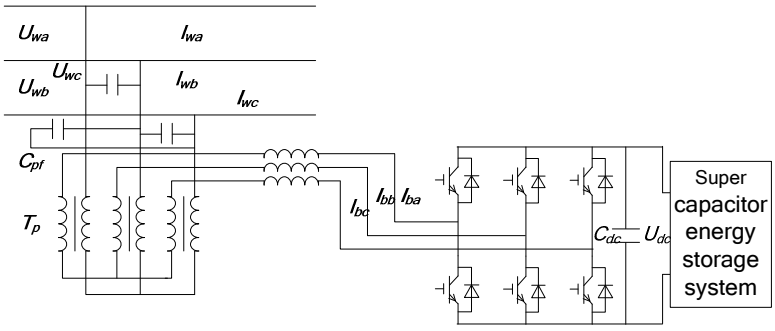

Fig.4 Circuit topology of parallel storage system

First, U_{wa}, U_{wb} and U_{wc} are transformed to U_{wd} and U_{wq} by DQ transformation. By the same way, I_{wa}, I_{wb} and I_{wc} are transformed to I_{wd} and I_{wq}, and I_{ba}, I_{bb} and I_{bc} are transformed to I_{bd} and I_{bq}. The parallel compensation is mainly used to smooth output power of new energy generation systems [9]. Therefore, active and reactive power is the control signal, and active and reactive power is respectively controlled in the steady-state conditions. Its inverter control diagram is shown in Figure 5.

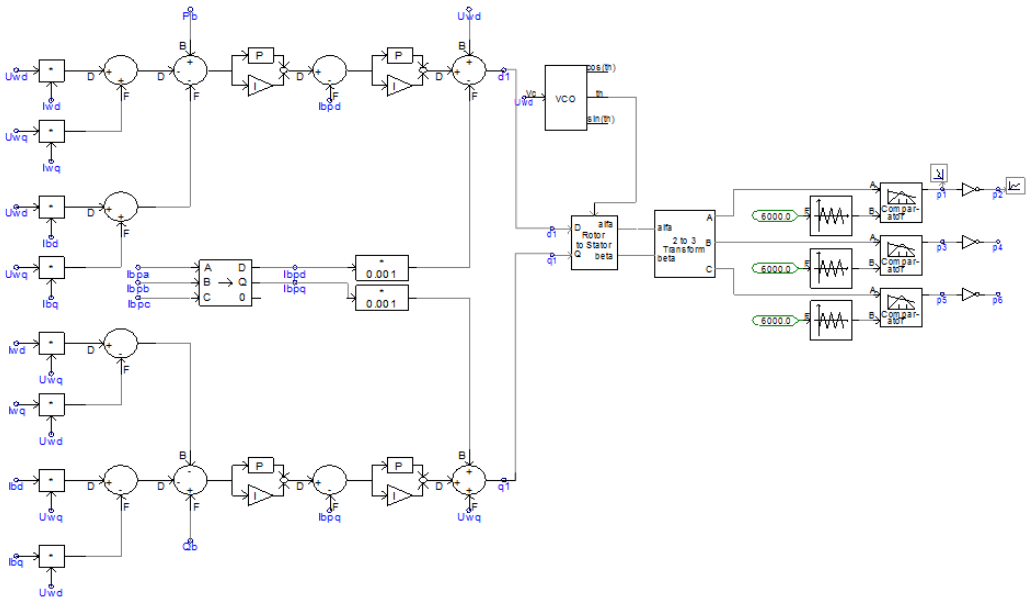

Fig.5 Parallel inverter control diagram

Control strategy of the series inverter

The circuit topology of series system is shown in Figure 6. It is connected to new energy power system through the transformer T_s. Phase voltage drop of transformer T_s is named as U_{ca}, U_{cb}, U_{cc}. The filtering capacitor is C_{sf}, current flowing into C_{sf} is I_{bsa}, I_{bsb}, I_{bsc}, and filter inductor is L_{sf}, voltage after L_{sf} is U_{bsa}, U_{bsb}, U_{bsc}. Through DC voltage converter rectified as U_{dcs}, DC capacitor is C_{dcs}. DC side is connected to super capacitor energy storage module.

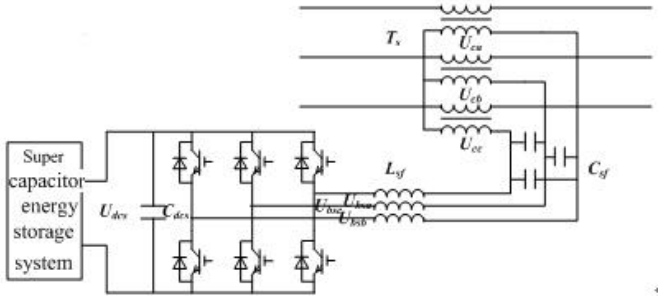

Fig.6 Circuit topology of parallel series system

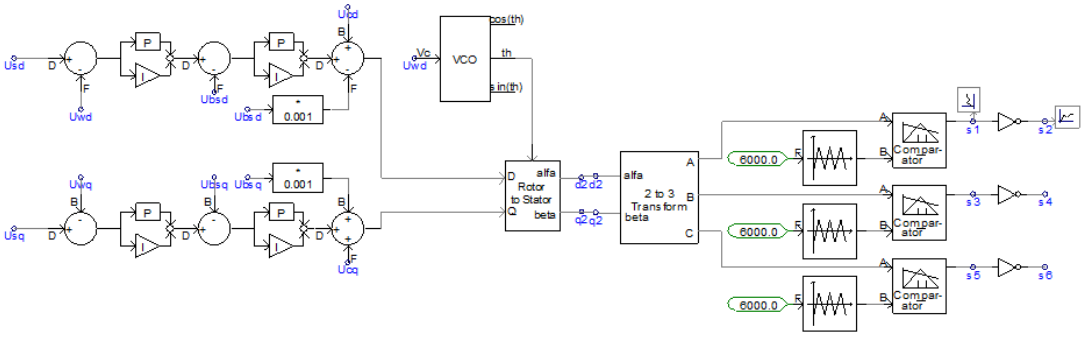

Fig.7 Series inverter control diagram

First U_{sa}, U_{sb}, U_{sc} are transformed to U_{sd}, U_{sq} by DQ transformation. By the same way, U_{bsa}, U_{bsb}, U_{bsc} are transformed to U_{bsd} and U_{bsq}; U_{ca}, U_{cb}, U_{cc} are transformed to U_{cd}, U_{cq}. Series compensation can change the characteristics of the natural distribution line voltage by inserting a voltage source [6]. The connected-grid voltage of new energy generation systems is the control signal for controller. The inverter control diagram is shown in Figure 7.

Simulation

The simulation model is established in PSCAD/EMTDC, with series and parallel energy storage system connected to double-fed wind power generation system. At 0.5s, active power has a short drop, and double-fed induction motor absorbs reactive. During 0.5s-4s, output active is about 0.5MW. At 4s, the average wind speed increases by 1m/s, active power increases to 0.8MW, double-fed induction motor does not output or absorb reactive power. Active and reactive waveforms are shown in Figure 8.

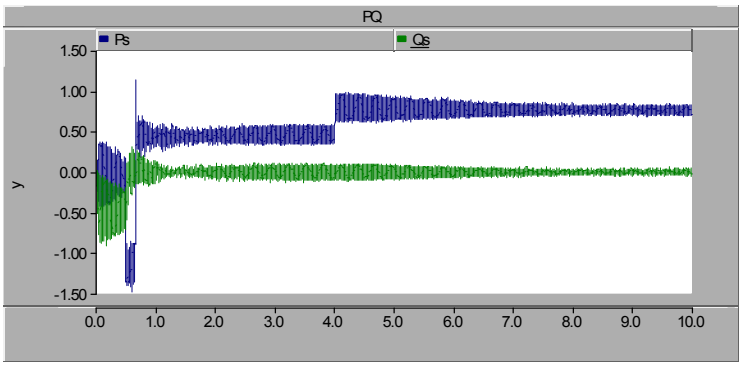

Fig.8 Active and reactive waveforms before utilizing the device

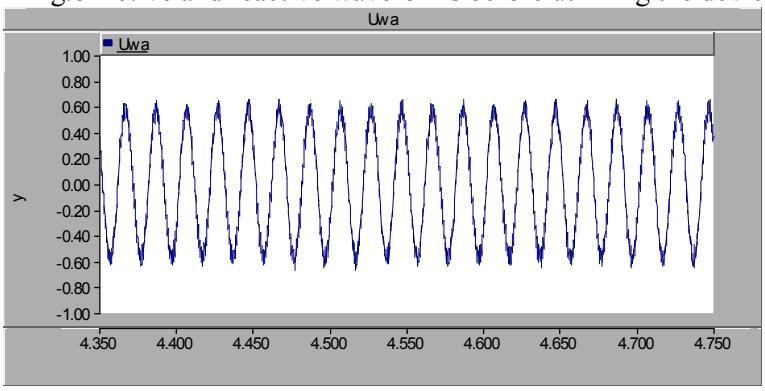

Fig.9 Connected- grid voltage before utilizing the device

It can be seen that active waveform fluctuations is in the wide range of about 0.2-0.3MW without super capacitor energy storage system. At the same time, connected-grid voltage amplitude of wind power generation system is about 0.6kV, and voltage harmonic is serious as shown in Figure 9.

After utilizing the series and parallel energy storage system of super capacitors, active and reactive power waveforms are shown in Figure 10. Compared with previous figure, active power and reactive power fluctuations are significantly reduced, achieved power smoothing.

After utilizing the series and parallel energy storage system of super capacitors, the voltage waveform of connected-grid side is shown in Figure 11. The voltage harmonic is reduced obviously.

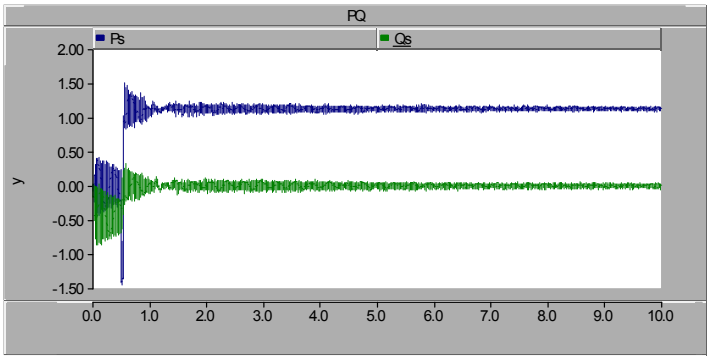

Fig.10 Active and reactive waveforms after utilizing the device

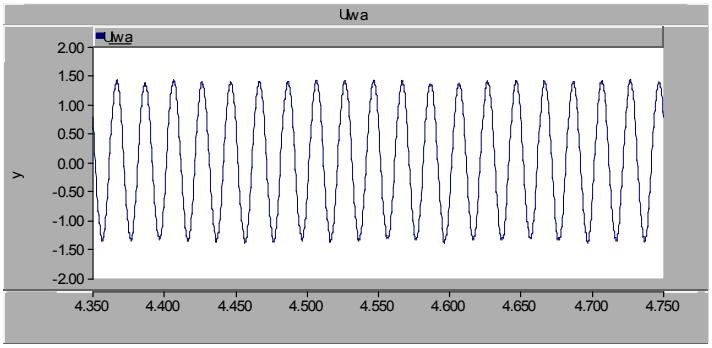

Fig.11 Connected- grid voltage before utilizing the device

Summary

In this paper, the series and parallel energy storage system based on super capacitor is designed, which achieves a wide range and fast regulation for active and reactive power in two directions and is able to improve power quality. Simulation results show the effectiveness of the above conclusion.

Keywords: nonsmooth bifurcation, chaos, cracked rotor-active magnetic bearings

Abstract. A cracked rotor-active magnetic bearings (AMB) system with the time-varying stiffness is modeled by a piecewise smooth system due to the breath of crack in a rotating shaft. The governing nonlinear equations of motion for the nonsmooth system are established and solved with the numerical method. The simulation results show that a grazing bifurcation, period-double bifurcation and chaotic motions exist in the response. These nonsmooth bifurcations can give rise to jumps between periodic motions, quasi-periodic motions and chaos.

Introduction

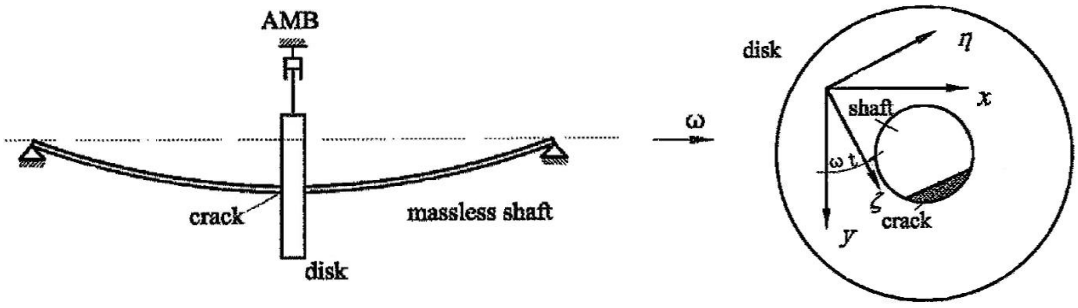
Active magnetic bearings (AMBs) present a technology that has many advantages compared to traditional bearing concepts and have been used in many engineering applications, for example, mechanical engineering, aeronautic engineering, astronautic engineering and many others. Research on the properties of the nonlinear dynamics and stability for the rotor-AMB system has received more attentions in the recent years [1,2].

Fatigue cracking of the rotor shaft is an important fault observed in the rotating machinery which can lead to catastrophic failure. So, detailed investigation into the dynamic response of a rotor with crack in the shaft is very important for diagnosing and preventing rotor cracks. For a cracked rotor, the crack opens and closes with rotation. When the crack is opening, the material shaft stiffness will decrease. When the crack is closed, the shaft stiffness will return to the value identical to that of the noncrack shaft. The rotating shaft has a discontinuous stiffness value, so the system is piecewise smooth. A great deal of research effort has been devoted to the study of the nonlinear responses and the transition to chaos of cracked rotors [3,4]. For piecewise smooth systems, there exist some nonconventional bifurcations, i.e., grazing bifurcation and sliding bifurcation. The nonconventional bifurcation, which was defined as nonsmooth bifurcation, may occur when a system solution collides one of the state-space boundaries, as the system parameters are varied [5].

In this paper, we investigate nonsmooth bifurcations in a cracked rotor-AMB system with time-varying stiffness. At first, the governing nonlinear equation of motion is established for the rotor-AMB system with the quadratic and cubic nonlinear terms. Then the effect of using controller parameters on the dynamics of the active cracked rotor is analyzed.

Model and Equations of Motion

Rotor Model. The rotor system to be studied, as in [3], is a massless flexible shaft with a central disc, which is supported on two identical rigid bearings as shown in Fig. 1a. In order to simplify the analysis, an AMB is located at the disc position as a damper in order to control the vibration of the disc. There is a transversal crack close to the middle disc. The stiffness of the uncracked rotor system is symmetric and the damping at the middle disc due to the air resistance effect is viscous.



(a) (b)

Fig. 1. The cracked rotor model with an AMB.

Crack Model. The switching crack model (also known as hinge model) is often used to simulate the crack breathing in rotors, as shown in Fig. 1b. The typical behavior of the crack (the breathing of the crack under weight influence) is described by the very simple model of Gasch [6]. When crack is open, the local stiffness of shaft will have a decrease of stiffness, which depends on the crack's depth. When crack is closed, the stiffness will be identical with that of the noncracked shaft. The opening and closing of crack are dominated by the sign of ζ : If $\zeta > 0$, the crack bears the tension stress and opens; if $\zeta \le 0$, the crack bears compression stress and closes.

Let f is the switch function that represents the opening and closing of crack with rotation, and

$$f(\zeta) = \begin{cases} 1 & \zeta > 0 \\ 0 & \zeta \le 0 \end{cases}. \tag{1}$$

The transfer matrix between rotating coordinates and fixed coordinates is

$$\begin{bmatrix} \zeta \\ \eta \end{bmatrix} = \begin{bmatrix} \sin \omega t & \cos \omega t \\ \cos \omega t & -\sin \omega t \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}. \tag{2}$$

So $\zeta = x \sin \omega t + y \cos \omega t$. While the rotor is running, the ζ is varied with t. When ζ transverses the critical value 0, the stiffness will switch back and forth between two values. That makes the vector field piecewise smooth. And we call the line $\zeta = 0$ the switch line.

Equations of motion of the rotor system. The equations of motion of the rotor system in stationary Cartesian co-ordinates can be written as

$$\begin{bmatrix} m & 0 \\ 0 & m \end{bmatrix} \begin{bmatrix} \ddot{x} \\ \ddot{y} \end{bmatrix} + \begin{bmatrix} c & 0 \\ 0 & c \end{bmatrix} \begin{bmatrix} \dot{x} \\ \dot{y} \end{bmatrix} + K(t) \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 0 \\ mg \end{bmatrix} + me\omega^2 \begin{bmatrix} \cos \omega t \\ \sin \omega t \end{bmatrix} + \begin{bmatrix} F_x \\ F_y \end{bmatrix} \tag{3}$$

where x and y are the displacements of the disc in the stationary co-ordinate system, $K(t)$ is the stiffness matrix of the cracked shaft in the disc position, and

$$K(t) = \begin{bmatrix} \overline{k}_0 - f\Delta k \sin^2 \omega t & -f\Delta k \sin \omega t \cos \omega t \\ -f\Delta k \sin \omega t \cos \omega t & \overline{k}_0 - f\Delta k \cos^2 \omega t \end{bmatrix}, \tag{4}$$

where $\overline{k}_0$ is the stiffness of the uncracked shaft, Δk is the decrease of stiffness in the ζ direction when crack is opening. m is the equivalent mass in the disc position, c is the viscous damping coefficient, e is the imbalance eccentricity between the centre of the gravity and the geometric centre of the disc, g is the acceleration due to gravity, ω is the rotational speed of the rotor system, F_x and F_y are the feedback control forces produced by the AMB in the x and y directions, respectively, see [1] in detail.

For the simplicity in computation, we transform the above motion equations into a dimensionless form. Dividing both sides by $m\omega^2\delta_{st}$, one obtains the non-dimensional equations of motion of the cracked rotor system with the AMB as

$$\ddot{X} + \frac{2\xi}{\Omega}\dot{X} + \frac{1+\alpha_1}{\Omega^2}X - \frac{f\Delta K}{\Omega^2}(X \sin^2 \tau + Y \sin \tau \cos \tau) = U \sin \tau + \frac{\overline{F}_x}{\Omega^2}, \tag{5a}$$

$$\ddot{Y}+\frac{2\xi}{\Omega}\dot{Y}+\frac{1+\beta_1}{\Omega^2}Y-\frac{f\ \Delta K}{\Omega^2}(X\sin\tau\cos\tau+Y\cos^2\tau)=U\cos\tau+\frac{\overline{F}_y}{\Omega^2}, \tag{5b}$$

where

$$\overline{F}_x=\left(3\mu_2X^2+3\mu_3X\dot{X}+\mu_2Y^2+2\mu_3Y\dot{Y}\right)\dot{X}+\left(2\mu_2XY+\mu_3X\dot{Y}\right)\dot{Y}+\mu_4X\dot{Y}+\mu_4\dot{X}Y$$
$$+\alpha_2X^3+\alpha_3XY^2+\alpha_4XY+(-2f_{11}X+f_{12}XY)\cos(w\tau),$$
$$\overline{F}_y=\left(3\mu_2Y^2+3\mu_3Y\dot{Y}+\mu_2X^2+2\mu_3X\dot{X}\right)\dot{Y}+\left(2\mu_2XY+\mu_3\dot{X}Y\right)\dot{X}+\mu_4X\dot{X}+\mu_5Y\dot{Y}$$
$$+\beta_2Y^3+\beta_3X^2Y+\beta_5X^2+\beta_6Y^2+(-2f_{21}Y+f_{22}Y^2+f_{23}Y^2)\cos(w\tau),$$

where $X=x/\delta_{st}$; $Y=y/\delta_{st}$; $U=e/\delta_{st}$ is the rotor imbalance parameter, $\xi=\overline{\mu}/2m\omega_{cr}$ is the viscous damping ratio, $\Omega=\omega/\omega_{cr}$ is the rotational speed ratio, δ_{st} is the corresponding deformation of the shaft due to the weight of the rotor, $\omega_{cr}=\sqrt{k_0/m}$ is the critical speed of the uncracked rotor, k_0 is the stiffness of the uncracked rotor, $w=\tilde{\omega}/\omega$ and $\tau=\omega t$ is non-dimensional time. The prime refers to differentiation with respect to τ. The other parameters are ignored here.

Simulations and Analysis.

In this section nonlinear behavior of the cracked rotor is examined. In order to investigate the bifurcation characteristics, we take rotational speed Ω as control parameter and its effect on nonlinear dynamic response has been undertaken in the present work. Using the following rotor configuration, the dynamic response is studied using bifurcation diagram, orbit plot and Poincare map. Selected parameters values: $\alpha_i=-0.1,0.5,0.2,-0.5,\ i=1,2,3,4;$ $\beta_i=-0.3,0.3,0.3,-0.25,0.6,\ i=1,$ $2,3,5,6;\ u_i=-0.5,-0.4,0.5,1.7,\ i=2,3,4,5;\ f_{12}=0.6;\ f_{21}=f_{11},\ f_{2i}=0.3,1.02, i=2,3$; $\xi=0.01,$ $w=2.5$. For the disc's position of cracked rotor, if ζ (ζ represents the displacement of the disc in the ζ direction) touches tangentially the switch line $\zeta=0$, a grazing bifurcation will take place.

Fig. 2 provides the bifurcation behavior of the cracked rotor ($\Delta K=0.6,\ f_{11}=0.19,\ U=0.1$). The rotating speed ratio Ω is taken as the control parameter, which is defined as the ratio of rotation speed to the natural frequency of the uncracked rotor. It can be seen from Fig. 2 that, as the speed increases, there are obviously four chaotic zones. the rotor motion experiences period-double bifurcation, grazing bifurcation ($\zeta=0$) and chaos.

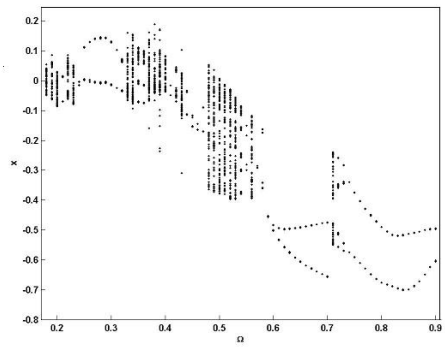


Fig. 2 Bifurcation diagram at $\Omega=0.18$ to 0.9.

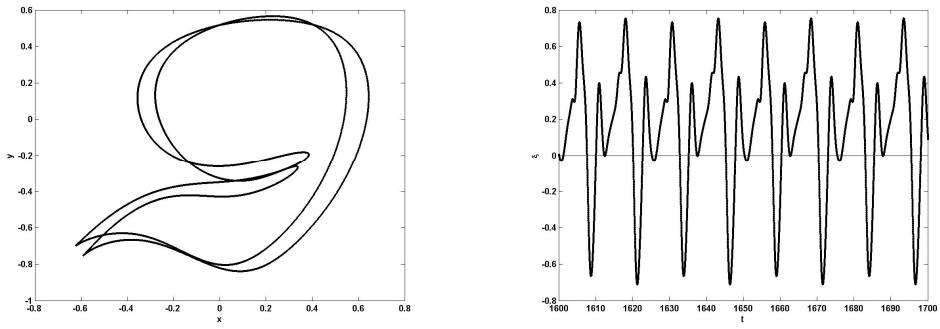
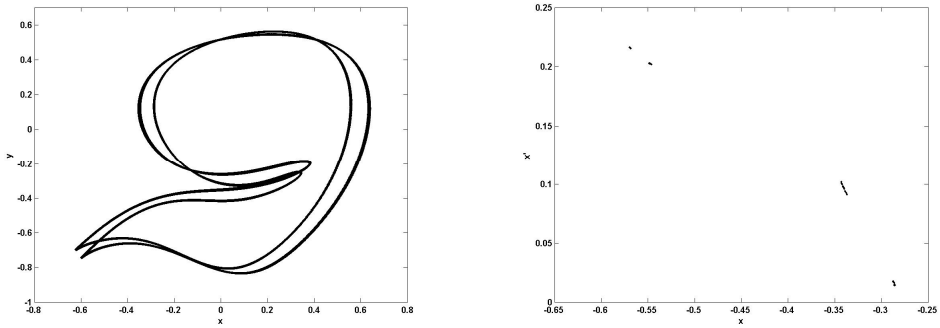
(1) Period-double bifurcation. Fig. 2 shows that there are several period-double bifurcations. Near $\Omega=0.59$ and $\Omega=0.75$, period-double bifurcation and inverse period-double bifurcation occur.

(2) Gazing bifurcation. There are two grazing periodic-4 motions at $\Omega=0.729,0.726$. Fig. 3 shows phase portraits, the switch line and Poincare sections at $\Omega=0.729$. When Ω increases a little, $\Omega=0.731$, the responses turn to chaos as shown in Fig. 4. It is found that the grazing bifurcation can cause the response to turn to chaotic motion directly.



(a) Periodic-4 motion at $\Omega = 0.729$. (b) Grazing the switch line at $\Omega = 0.729$.

Fig. 3 Evolution of the response near at $\Omega = 0.729$.



(a) Chaotic motion at $\Omega = 0.731$. (b) Poincare section at $\Omega = 0.731$.

Fig. 4 Evolution of the response near at $\Omega = 0.731$.

Conclusions

This paper focuses on a cracked rotor-AMB system with quadratic and cubic terms and time-varying stiffness. First, the governing nonlinear equation of motion is established for the rotor-AMB system with two-degree-of-freedom. Then, the nonsmooth bifurcations of the system are investigated using numerical method. From the results，the following conclusions can be drawn. For the nonsmooth cracked rotor-AMB system, there exists grazing bifurcation and periodic bifurcation in the response. The grazing bifurcation can cause the response to jump from one periodic motion to chaos directly.

Keywords: aircraft, EMAS, Arresting, static analysis, dynamic model

Abstract. The EMAS of aircraft-pavement is a dedicated device that used to block aircraft overrunning the runway. To protect the safety of aircraft and passengers, the EMAS can safely arrest the overrun aircraft in an allowed distance and inertial load without injuring aircraft passengers and damaging aircraft. Combining with actual situation, this paper made statics and dynamics analysis under the action of the wheel of EMAS， and provides effective theoretical support for further research of EMAS of aircraft-pavement.

Introduction

With the development of the society, the air traffic is increasing. Because of the meteorological factors, mechanical accident, the driver reason and so on. How to reduce the suffered harm the plane on the runway accident effectively, ensure the safety of life on further, reduce the damage of aircraft, has become an urgent problem need to solve for the world's largest airport. Now the hydraulic system is used more than others[1], but the system structure is complex and has many shortcomings. EMAS can arrest aircraft has different quality and different speed, make it stop within a safe distance from causing serious damage for passengers and aircraft[2].

Current Situation of EMAS

EMAS is a new kind arrestor system of aircraft, laid by the lightweight foam concrete that tire can be pressed into. It is important security measures and usually installed at the end of the runway of the airport. At present, the ESCO corporation and FAA of the United States developed engineered materials arresting system(EMAS) has become a special equipment to arrest the plane overrun the runway[3]. The key technology of EMAS such as material research[4] and development, the mathematical model[5] establishment and structure design applied has been more mature in the United States[6], and the system has been applied widely in the United States, played an important role in the actual use. By the end of the April 4, 2014, EMAS has 74 runway at the airport in the United States has carried on the installation, there have been nine incidents where EMAS has safely stopped nine overrunning aircraft with a total of 243 crew and passengers aboard those flights[7].

Due to various reasons, Aircraft may overrun the runway during takeoff and landing, the tire will crushed and sunk into EMAS. In this process, the plane's kinetic energy translate into the energy of the crushed material. With increasing the distance of the plane into the EMAS, the height of the EMAS will also increase gradually, Foamed concrete will provide the wheel greater resistance moment, and finally the aircraft stopped at a safe distance.

Mathematical Model of EMAS

Interaction mechanism of wheel and foamed concrete. In order to determine the arresting performance of foamed concrete, we established the interaction model of the wheel and foam concrete. The model is a dynamic model of aircraft arresting system, as the plane drown EMAS, it can calculate the dynamic load acting on the wheel of foam concrete. The wheel for a given direction of motion, F_D is the horizontal total drag force between the tires of an aircraft and the arrestor materials, F_C is the overall total reaction force applied by the foamed concrete on the wheel. the resistance is

composed of four parts, Including foam concrete dynamic Crushing resistance $F_{D1,}$ tearing force $F_{D2,}$ adhesive resistance F_{D3} and equivalent friction F_{D4}.

1) Dynamic Crushing resistance. When the plane crossed into foam concrete, it will produces a rut with certain depth and width. The section between the wheel and the foam concrete is divided into two parts, i.e. the arc segment and the wheel footprint segment, as shown in Fig. 1.

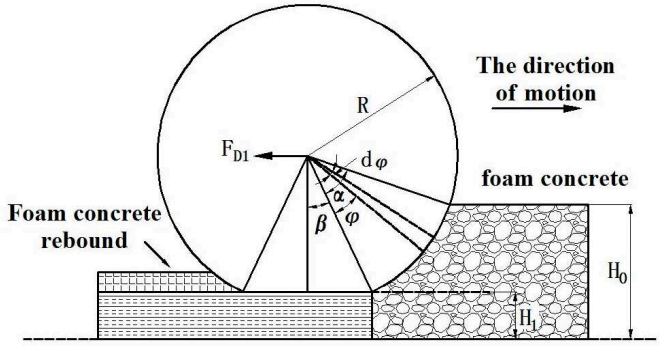

Fig.1. Schematic of the interaction between an aircraft tire and foamed concrete

H_0 is the initial height of the foam concrete and H_1 is compaction height in this diagram. R is the radius of wheel. The figure also defines the angleβ, calculated as follows:

$$\beta = arc\ \sin\ (\frac{Mg}{P_L B}) \tag{1}$$

Where M is the weight of aircraft, G is the acceleration of gravity, P_L is the tire pressure, t B is the effective width of wheel. According to the compression strength condition, the horizontal resistance under the incremental φ of angle dφ on wheels is

$$\mathrm{d}F_{H1} = \sigma_C BR\sin(\beta+\varphi)d\varphi \tag{2}$$

According to the mechanical properties of foam concrete, we assume that the stress-strain curve obeys a power law model[8]. The stress σ_C can be calculated as

$$\sigma_C = \sigma_0 + \mathrm{k}\varepsilon^{\mathrm{n}} \tag{3}$$

Where ε is compression strain of foam concrete, σ_0 is initial yield stress, k and n is the parameters associated with mechanical properties of the material. Based on the assumption that no relative sliding between tire and foam concrete, compression strain ε can be expressed as

$$\varepsilon = \frac{\sqrt{2}R}{H_0}\sqrt{1-\cos(\alpha-\varphi)} \tag{4}$$

Integrating between φ=0 and α gives the compressive resistance on one tire, get the horizontal compaction resistance

$$F_{D1} = BR\sigma_0[\cos\beta-\cos(\beta+\alpha)]+\frac{2^{\frac{n}{2}}kBR^{n+1}}{H_0^2}\int_0^{\alpha}\sin(\beta+\varphi)[1-\cos(\alpha-\varphi)]^{\frac{n}{2}}d\varphi \tag{5}$$

2) Tearing force. When the tire pressure through the foam concrete, it can tear on either side of the foam concrete, as shown in Fig. 1, tearing force F_{D2} can be expressed[9]

$$F_{D2} = 2\int_0^{\alpha}\gamma R\sin(\beta+\varphi)d\varphi = 2\gamma R[\cos\beta-\cos(\beta+\alpha)] \tag{6}$$

3) Adhesive resistance. When the tire rolling in the foam concrete, due to inertia effect, concrete under the tires move with the tyre tread in the tangent direction and produce resistance F_{D3}, as shown in Fig. 2

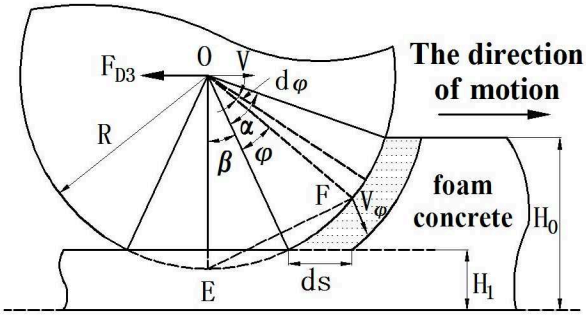

Fig.2. Adhesive resistance of tire Under pure rolling condition.

As the wheels speed in the horizontal direction is V, we can calculate the Vφ is

$$V_{\varphi} = 2V\cos(\frac{\beta+\varphi}{2}) \tag{7}$$

When the wheel moves forward a micro period ds, the kinetic energy dT of the micro section of foam concrete expressed as (1/2) • m • V_{φ}^2=F_{D3} • ds, eliminate ds and F_{D3} can be expressed

$$F_{D3} = \rho_0 BRV^2[\alpha + \sin\beta + \sin(\alpha+\beta)] \tag{8}$$

4) equivalent friction. In order to ensure that the aircraft can stop in a safe area of runway, the friction between the tire tread and runway should meet the document [10, 11]. After the wheel entering the EMAS, between the wheel and the concrete will produce two part friction, One part is the friction between the tire surface and the compressed foam concrete, another part is the friction between the wheel and the two side section of concrete. Because the side pressure is little, the side friction is negligible. equivalent friction F_{D4} can be expressed

$$F_{D4} = \mu F_C \tag{9}$$

Where μ is the equivalent friction coefficient. In conclusion, the total resistance of a single wheel by foam concrete is

$$F_D = F_{D1} + F_{D2} + F_{D3} + F_{D4} \tag{10}$$

Dynamic Equations of EMAS. The plane rush into the EMAS is a very complicated process, in order to get the system dynamics model, as shown in Fig. 3. We make the following assumptions and Simplification: The plane is the ideal rigid body, elastic deformation can be ignored; The plane motion only in the vertical plane; θ is a small inclination angle, less than $\pm 10^\circ$; To simplify the landing gear into the spring damper, the main gear elastic coefficient is K_M, damping coefficient is C_M, the nose gear elastic coefficient is K_N, damping coefficient is C_N.

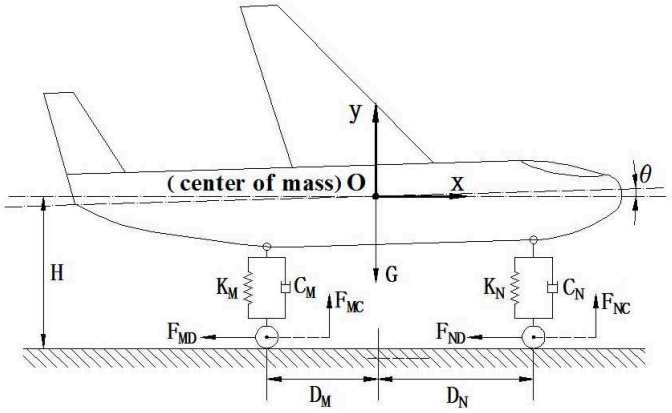

Fig.3. Aircraft dynamic model

The dynamic aircraft model has three degrees of freedom, which are aircraft horizontal traveling distance x, aircraft vertical displacement y, aircraft pitch angle θ,dynamic equations of the system are established by using the Lagrange equation.

1) kinetic energy of the system. The kinetic energy of the system including the plane translation and rotational kinetic energy as follows

$$E_K = \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}J_0\dot{\theta}^2 \tag{11}$$

2) potential energy of the system. Potential energy of system consists of gravitational potential energy and elastic potential energy as follows

$$E_P = mgy + k_M y_M^2 + \frac{1}{2}k_N y_N^2 = mgy + k_M[\frac{D_N}{2(D_M + D_N)k_M}(G - C_L \bullet \frac{1}{2}\rho V^2 S) + H - (y - D_M\theta)]^2 +$$

$$\frac{1}{2}k_N[\frac{D_M}{(D_M + D_N)k_N}(G - C_L \bullet \frac{1}{2}\rho V^2 S) + H - (y + D_N\theta)]^2 \tag{12}$$

Where y_M is the amount of compression of main gear spring damper, y_N is the amount of compression of nose gear spring damper, G is gravity of the plane, F_L is lifting force, CL is coefficient of lifting force, ρ is air density, S is wing area, D_M is A is the distance of main landing gear to the center of gravity, D_N is A is the distance of nose landing gear to the center of gravity.

3) Rayleigh dissipation function of the system. The landing gear is simplified as elastic damper, then there must exist a viscous friction, the Rayleigh dissipation function as follows

$$\psi = C_M(\dot{y} + + D_M\dot{\theta}) + \frac{1}{2}C_N(\dot{y} + D_N\dot{\theta}) \tag{13}$$

4) Establish dynamic equations. The Lagrange equation[12] as follows

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{q}_i} - \frac{\partial L}{\partial q_i} + \frac{\partial \psi}{\partial \dot{q}_i} = Q_i^{'} \tag{14}$$

Where $L=E_K+E_P$, q_i is generalized velocity, $Q_i^{'}$ is generalized dissipation force, substituting E_K and E_P into Eq. (14), the dynamic equations can be expressed as

$$\begin{cases} M\ddot{x} = -F_{ND} - 2F_{MD} \\ M\ddot{y} = (2C_M + C_N)\dot{y} - (2K_M + K_N)y + (C_N D_N + 2C_M D_M)\dot{\theta} + (2K_M D_M - K_N D_N)\theta + 2K_M \\ \quad + +2K_M[\frac{D_N}{2(D_M + D_N)k_M}(G - C_L \bullet \frac{1}{2}\rho V^2 S) + H] + K_N[\frac{D_M}{(D_M + D_N)k_N}(G - C_L \bullet \frac{1}{2}\rho V^2 S) + H] \\ J_0\ddot{\theta} = (2C_M D_M + C_N D_N)\dot{y} + (2K_M D_M - K_N D_N)y + (2C_M D_M^2 + C_N D_N^2)\dot{\theta} - (2K_M D_M^2 + K_N D_N^2)\theta \\ \quad - 2K_M D_M[\frac{D_N}{2(D_M + D_N)k_M}(G - C_L \bullet \frac{1}{2}\rho V^2 S) + H] + K_N D_N[\frac{D_M}{(D_M + D_N)k_N}(G - C_L \bullet \frac{1}{2}\rho V^2 S) + H] \\ \quad - (2F_{MD} + F_{ND})y - 2F_{MC} \bullet D_M + F_{NC} \bullet D_N \end{cases} \tag{15}$$

Conclusions

This paper established the static and dynamic analysis model of aircraft pavement engineering material arresting system, got the resistance and support force of the landing gear and the main landing gear by the plane. At the same time ,we also obtained the mathematical function of dynamic compaction resistance and the density of crushed the foam concrete material, they plays an important role in arresting the aircraft. In addition, we have reasonable assumptions and analysis for the collapse of transient. The aircraft model is reasonably simplified and established dynamic equations of the system. Later the dynamics simulation further verify the reliability of the model. In addition, this article can be for the material density, height and size or other factors determine and for the true test is a direct support of the theory. In this paper, research methods and strategies of aircraft also has reference significance for the further study of the pavement EMAS.

Then, I want to express my gratitude to all those who helped me during the writing of this thesis. My deepest gratitude goes first and foremost to Professor Yu Hongbin, my supervisor, for his constant encouragement and guidance. He has walked me through all the stages of the writing of this thesis. Without his consistent and illuminating instruction, this thesis could not have reached its present form.

I am also deeply indebted to all the other tutors and teachers in Translation Studies for their direct and indirect help to me. Special thanks should go to my friends who have put considerable time and effort into their comments on the draft.

Finally, I am indebted to my parents for their continuous support and encouragement.

Keywords: automotive wind tunnel, contrast test, aerodynamics, reference car models

Abstract. The aerodynamic drags of different reference car models were investigated to calibrate the performance of the Automotive Wind Tunnel in Jilin University. The two kinds of reference models--MIRA and SAE reference car models were involved in this paper, considering the actual situation of the Automotive Wind Tunnel in Jilin University. The results of the research show that the Automotive Wind Tunnel in Jilin University can meet the demand for automotive wind tunnel tests and it can get the same performances as other wind tunnels have and reliable test data can be obtained in it.

Introduction of wind tunnel test

Road vehicle aerodynamics plays a critical role in car design and the road vehicle aerodynamics focuses on investigating the interaction between flow air and vehicles. Aerodynamic coefficients are one of the most important parameters. It has great effects on automotive dynamics, handling and stability.[1] Researches have been conducted mostly on scale reference models to investigate flow characteristics and aerodynamic forces and moments and to correct and compare results in different automotive wind tunnels.[2]

Recently under the increasing fuel problem and high-speed travel of vehicles, aerodynamic drag reduction of road vehicles, which affect their fuel economy, is being pay close attention to[3-4]. So many wind tunnels focusing on aerodynamics of road vehicle were built in different countries[5].

Now, there are many kinds of wind tunnels all around the world, but there are hardly any two wind tunnels are exactly same, so the test results in each wind tunnel vary more or less. According to the description of certain documents, contrast tests were conducted between automotive wind tunnel and aeronautic wind tunnel for testing vehicles such as the wind tunnel of NRCC(Network Routing Control Center), LOCKHEED Wind Tunnel and so on. The test results show that aerodynamic drag figures tested in different wind tunnels are different. According to the reports, those automotive wind tunnels of which the test results have great differences have been improved and now their test data are already very close. [5]

The Automotive Wind Tunnel in Jilin University

The Automotive Wind Tunnel in Jilin University began to be built in May, 2002 and was completed in 2008. This paper compares the Automotive Wind Tunnel in Jilin University with other automotive wind tunnels by testing the reference car models .

The Automotive Wind Tunnel in Jilin University is equipped with special six-component balance system, rolling road (or moving belt) system, aerodynamic pressure scanner system and other specialized measuring systems. The balance system consists of force sensors and model supporting structure. The overall accuracy of sensors and data acquisition system is under 0.05%F.S. (Full Scale).

The main technical parameters:The test section size: 8m(length)×4m(width)×2.2m(height); Maximum wind velocity: 60m/s; Contraction ratio: 5.17; Power of the main motor: 1000kw; Range of the rotating table: ±30°.

The Automotive Wind Tunnel in Jilin University is a closed circuit wind tunnel. It has an open test section as shown in Fig.1. For the existing of the moving belt system of the Automotive Wind Tunnel in Jilin University and the automobile wind tunnel assembles the balance, this paper adopts the wheel center supporting system as shown in Fig.2. The support position of this kind of supporting system is not the car tires but the car wheels. The car balance of this kind of supporting system lies at the bottom of the automotive wind tunnel test section and four supporting columns reach out from the balance to the wind tunnel test section. The supporting columns are connected to the axletree through a transversal horizontal rod to fix the automotive car models.

Fig. 1. The test section

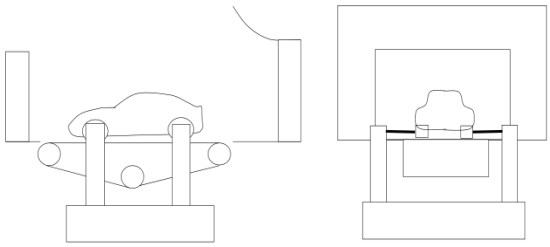

Fig. 2. The supporting system

The test section of the Automotive Wind Tunnel in Jilin University is open test section, and the mechanical balance is installed at the bottom of the test section. The automotive wind tunnel is equipped with the rolling road ground effects simulation system and it adopts wheel center supporting system to reduce the blocking effect, to take the advantages of the simulation system for the rolling road ground effects, to avoid transformation of the car and to obtain the aerodynamic force accurately. But the Automotive Wind Tunnel in Jilin University cannot get the original aerodynamic coefficients data directly because of the interference of the aerodynamic force of supporting columns. Considering these situation, this paper has deducted the interference of the supporting columns aerodynamic force before obtaining the final test results. So the test results obtained in this paper at last is accurate.

Introduction of the experiment

To arrive at an accurate experimental conclusion, this paper compares test results of the Automotive Wind Tunnel in Jilin University with test results of the other automotive wind tunnels with reference to certain automotive car models. The technical precept will be described following. Firstly, select standard car models for reference and design the supporting forms according to the actual situation of the Automotive Wind Tunnel in Jilin University. Secondly, manufacture the real object models according to the geometric dimensioning data of the car models. Thirdly, complete the wind tunnel test with the real object models and measure the aerodynamic force by ways of wind tunnel test. Finally, complete the data processing on the basis of the test results and compare the obtained data with test results of other automotive wind tunnels and then come to an accurate conclusion.

The reference models

To conduct the wind tunnel contrast test and come to an accurate conclusion, the car models selected for reference should be of geometric similarities, of high comparability, easy to meet the demands of the automobile standards. Besides, the car models should also posses test data of other automotive wind tunnels and must be representative, universal and have deferent forms.

Considering the construction demand of the Automotive Wind Tunnel in Jilin University and the actual situation of the paper, this paper selects the MIRA and SAE car models[6,7] as the standard models for reference. The test is conducted with the car models made at the rate of 1:2 to obtain more accurate data.

The MIRA car models are simplified vehicle car models which are very close to real vehicles. The MIRA car models have wheels but do not have wheel cavity. The bottom of the model is very smooth and the engine hood has certain angel of slope. The side windows of the car models incline and the tail of the model warps upward. There are totally four forms of the MIRA car models: the notchback, the fastback, the square back and the pickup[7,8].

The SAE car models are relatively simple body car models. Only certain planes and edges of the SAE car models are chamfered. The SAE car models do not have wheels or wheel cavities. But at the bottom, there are four small columnar legs to fix the car models. Besides, a diffuser is set at the end of the bottom. There are also four forms of the SAE car models in total: the notchback, the fastback, the squareback and the hatchback[7]

Both the MIRA and the SAE car models are in possession of abundant wind tunnel test data and these data provide good reference for the research in this paper. In terms of the need of the research, this paper has summarized the test data for contrast research of the two models on the basis of large quantities of reference and information[6-8] as shown in Table Cd in reference.1. In this paper, the contrast test is conducted based on the test results in Table1.

Test precepts based on standard model cars

Considering the actual situation of the Automotive Wind Tunnel in Jilin University, this paper designs four series of test precepts based on the two standard car models. Part of the MIRA and SAE car models' process are shown from Figure 3 to Figure 9. One of the test precepts of the MIRA car models is shown from Figure 3 to Figure 6 and they respectively show the test process of the notchback, the fastback, the pickup, and the square back of the MIRA car models. In this precept, because of the four wheels at the bottom of the car models, a Z-shape supporting rod is stuck beside the four wheels assisted by a certain amount of glue.

Fig. 3. MIRA model1

Fig. 4. MIRA model2

Fig. 5. MIRA model3

Fig. 6. MIRA model4

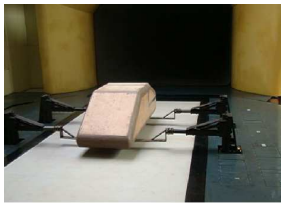

Fig. 7. SAE model1

Fig. 8. SAE model2

Fig. 9. SAE model3

One of the test precepts of the SAE car models is shown from Figure 7 to Figure 9 and they respectively show the test process of the fastback, the notchback, and the square back of the SAE car models. In this precept, because there are no wheels or other attachment to get stuck at the bottom of the model, some screws are installed at the bottom of the body to fix the SAE car models to ensure the stability of the model.

Contrast of the test results

The Figure 10 shows the contrast of the test results of the upbody surface aerodynamic force between Jilin University and the test data of IVK/FKFS Universität Stuttgart. The blue scatter points are made based on the upbody test data of IVK/FKFS Universität Stuttgart and the red scatter points is made based on the upbody test results of Jilin University. By contrast, it can be found that there exists errors between the upbody test results of Jilin University and IVK/FKFS Universität Stuttgart. But on the whole, the consistency is good. The Figure 10 doesn't show the contrast of the test results of the downbody surface aerodynamic force between Jilin University and IVK/FKFS Universität Stuttgart. In the contrast test, it is found that there's a larger error of the downbody. But the overall trend is still the same.

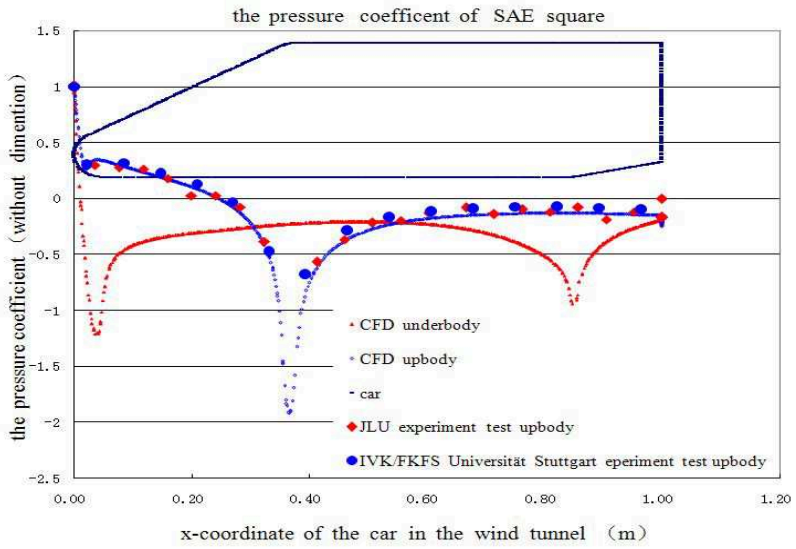

Fig. 10. The contrast of the body surface

The Table 1 shows the contrast results of test data between Jilin University and other wind tunnels. It can be found that there exist certain errors between the Automotive Wind Tunnel in Jilin University and other wind tunnels. The contrast error of the pickup of the MIRA automotive car models is the least, only 0.63%, while the contrast error of the square back of the MIRA automotive car models is the largest, to be 1.94%. The contrast errors of the other forms of the automotive car models are within this scope. On the whole, the contrast errors are all within 2%.

Table. 1. The contrast results between Jilin University and other wind tunnels

No.	The car models	Cd in reference	Cd in Jilin University	Error
1	Notchback of MIRA	0.30	0.303	0.83%
2	Fastback of MIRA	0.27	0.265	-1.70%
3	Square back of MIRA	0.35	0.357	1.94%
4	Pickup of MIRA	0.32	0.322	0.63%
5	Notchback of SAE	0.21	0.210	-0.14%
6	Fastback of SAE	0.23	0.226	-1.61%
7	Square back of SAE	0.29	0.294	1.28%

Through the contrast above, it can be found that there exist differences between the Automotive Wind Tunnel in Jilin University and other wind tunnels. There are certain errors between the test data, but on the whole, the error is very small. It indicates that the quality of the Automotive Wind Tunnel in Jilin University is high and it can meet the needs for automotive wind tunnel tests.

Conclusion

This paper analyzes the structure layout of the Automotive Wind Tunnel in Jilin University on the basis of summarizing the forms of test section and model supporting structure at home and abroad and then compare the test data of the Automotive Wind Tunnel in Jilin University with test data of other wind tunnels after determining the test precept and conducting the automotive wind tunnel test. The research results show that the precision can meet the needs and that the quality of the Automotive Wind Tunnel in Jilin University is high and it possesses the same performances as other wind tunnels have. Therefore, reliable test data can be obtained through automotive wind tunnel test conducted in it.

Keywords：Coordinated control system, load control mode, signal constraint, simulation.

Abstract. The boiler-turbine coordinated system is a very important process of a power generation unit. This paper takes 300MW power plant as the controlled object and conducts simulation study on its different kinds of load control modes under the environment of the MATLAB. The parameters of PID controller are optimized using signal constraint (S-C) module in Simulink toolbox. By analyzing the results of the simulation and comparing both the advantages and disadvantages of them, we can provide references for the choices of load control mode of power unit.

Introduction

The thermal power unit is a nonlinear, inter-coupling, large inertia, large delay, multi-variables and time-varying complicated controlled object, which has many uncertain factors [1]. At present, the unit power plants with great power and big parameters have been widely used, which are operated in a load following mode due to the rapid development of power industry. As a key component of power network automatic generation control (AGC), the coordinated control system (CCS) of fossil-fueled generating units play a vital role in the safe and economic operation. It is required that the boiler-turbine-generator set reacts to the load demand change quickly. While, it must make sure that the set can perform safely, stably and economically. Consequently, it is crucial to choose the best control strategy according to different units to develop good control qualities [2].

Coordinated Control System Structure

When the coordinated control system receives the real power command N_0 from load command management center, the boiler-turbine coordinated controller will send the boiler firing rate (coal feeder speed) command B and opening degree of the steam turbine regulating value command μ to corresponding local control loop respectively based on some control method.

The load command management center and boiler-turbine coordinated controller have many realization forms. And the system might not be definitely divided into two parts either. For the purpose of discussions, the two parts will be discussed separately. As for boiler and turbine command local control loop, we can group them into generalized objects. Therefore, the block diagram of simplified coordinated control system is given as Figure1.

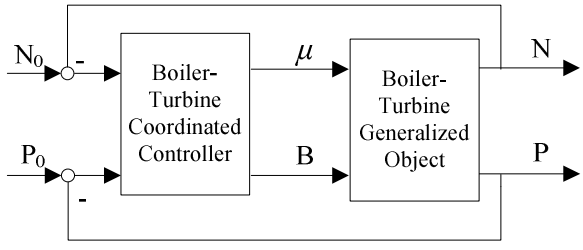

Fig.1 Simplified coordinated control system in unit plant

Controlled Object Model

The boiler-turbine coordinated control system can be simplified as a multiple-input multiple-output (MIMO) system. B and μ are input variables, N and P are output variables. B is the command variable about boiler firing rate (coal feeder speed) and μ is the command variable about the opening degree of the steam turbine regulating value. N is the real power that generating unit outputs and P is the main steam pressure.

In this paper, we take the 300MW coal-fired once-through power plant unit as the study object. The linearized mathematical model of this unit plant under the 100% load operation condition is described by [3]:

$$\begin{bmatrix} N \\ P \end{bmatrix} = \begin{bmatrix} W_{11}(s) & W_{12}(s) \\ W_{21}(s) & W_{22}(s) \end{bmatrix} \begin{bmatrix} \mu \\ B \end{bmatrix} \tag{1}$$

Where:

$$W_{11}(\mathrm{s}) = \frac{4.665s(1+99s)}{\left(1+50s+58^2 s^2\right)(1+4.1s)} \tag{2}$$

$$W_{12}(\mathrm{s}) = \frac{2.069(1+311s)}{(1+149s)^2(1+22.4s)} \tag{3}$$

$$W_{21}(\mathrm{s}) = -1.42\left(0.04+\frac{0.96}{1+70s}\right) \tag{4}$$

$$W_{22}(\mathrm{s}) = \frac{1.265(1+205s)}{(1+128s)^2(1+11.7s)} \tag{5}$$

Signal Constraint Optimization of PID Parameters

To compare the control qualities of different load control modes, we should eliminate the influence of the controller's parameters of each control method. In order to achieve the best control state of current method, Signal Constraint (S-C) module in Simulink toolbox is introduced to optimize the PID parameters [4].

First, we make constraint on the upper and lower boundary of expected curve and set up initial value of PID parameters. Then, we select the optimal parameters and optimization method. In this article, Gradient Descent is adopted for its faster rate of convergence than others. Finally, by constantly increasing constraint of the expected curve until, we can receive the best control effect.

Simulation and Comparative Analysis

To compare different kinds of load control modes' performance about rapid response to grid load and maintaining the pressure stability, each simulation process is conducted under the test of power setting value step disturbance and pressure setting value remaining unchanged. In the figures below, W_T is turbine PID controller and W_B is boiler PID controller. Red line represents N curve and blue line represents P curve.

A. Turbine and Boiler Separate Control Mode

The separate control mode means one controlled variable can be only controlled by one manipulated variable. There are two basic kinds of separate control mode: boiler following control and turbine following control mode [5].

a) Boiler Following (BF) Control Mode

The principle of boiler following control mode is that turbine controller regulates the unit power and boiler controller regulates the steam pressure.

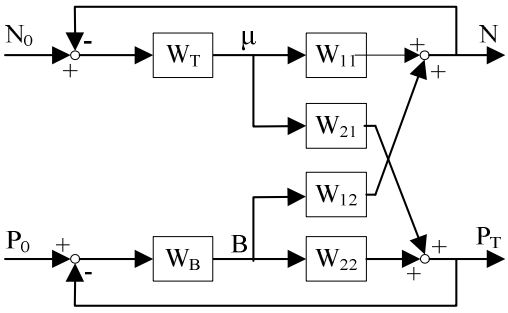

Fig.2 Structure of BF mode

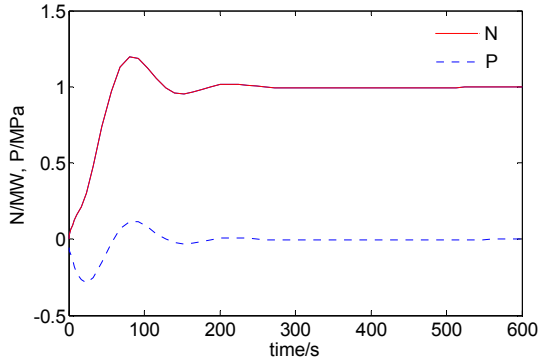

Fig.3 Simulation curves of BF mode

Using the methods mentioned above, we can get the best curve of output which is shown in Fig.2: the parameters of turbine PID controller: kp=1, ki=0.0159, kd=0; the parameters of boiler PID controller: kp=4, ki=0.097, kd=0.

The result shows that the unit power tracks the set value rapidly, but the main steam pressure has a great fluctuation. It also verifies that boiler following control mode has a great adaptability to the power and an unacceptable fluctuation in the main steam pressure, which uses boiler heat storage.

b) Turbine Following (TF) Control Mode

The principle of boiler following control mode is that turbine controller regulates the steam pressure and boiler controller regulates the unit power.

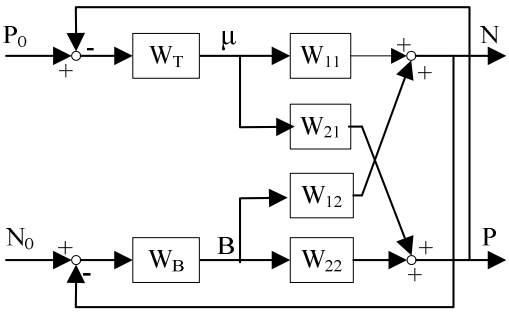

Fig.4 Structure of TF mode

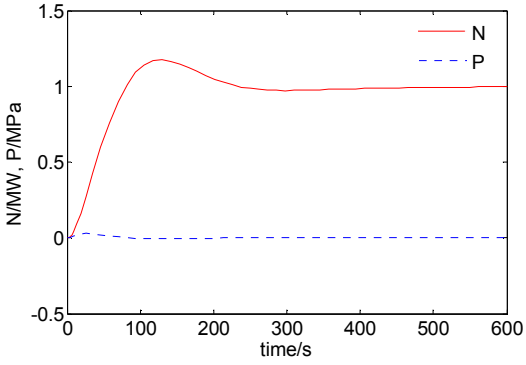

Fig.5 Simulation curves of TF mode

The parameters of turbine PID controller: kp=-11.4272, ki=-0.5, kd=-5.0501; The parameters of boiler PID controller: kp=0.7, ki=0.015, kd=0.7702.

Compared with boiler following control mode, the fluctuations of main steam pressure under this mode are maintained within a small range. However, the curve of power reaches the given value slowly after the first peak. That is to say, the unit power will begin to change only when the main steam pressure is changing after the boiler firing rate has been changed under this kind of control mode.

B. Coordinated Boiler-turbine Control Mode

Both turbine following control mode and boiler following control mode are extreme situations. They cannot balance the contradiction between unit power and main steam pressure. Coordinated boiler-turbine control system makes boiler and turbine as a whole and the control methods were introduced into the controller, such as feed-forward, compensation and so on [6]. There are many

forms of coordinated control mode; we choose three typical strategies to research their respective control qualities.

a) Unidirectional Decoupling Boiler Following (BF) Coordinated Control Mode

This kind of coordinated control mode is based on boiler following control mode and introduces the pressure deviation into boiler controller.

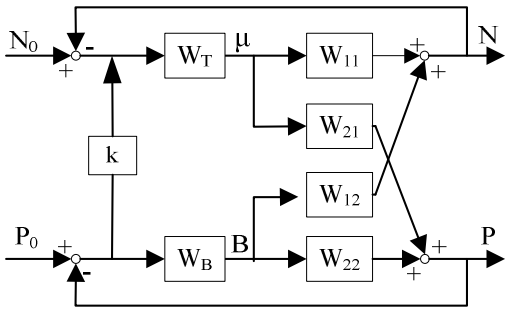

Fig.6 Structure of unidirectional decoupling BF mode

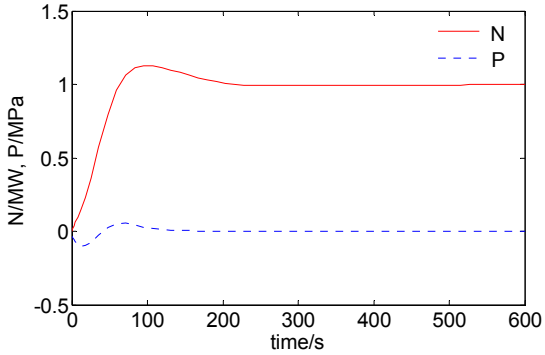

Fig.7 Simulation curves of unidirectional decoupling BF mode

The parameters of turbine PID controller: kp=0.5175, ki=0.0178, kd=0.0102; The parameters of boiler PID controller: kp=4.5168, ki=0.0628, kd=-0.0133; decoupled coefficient k=0.2.

When N_0 changed，turbine controller alter the opening degree of turbine valve to change the steam flow，so that N will rapidly approach to N_0. Changes in the heat storage lead to steam pressure changes, and then according to the pressure deviation signal, turbine and boiler controllers regulate the boiler firing rate and opening degree of turbine valve respectively at the same time. On the one hand, boiler heat storage is compensated by the change of boiler firing rate. On the other hand, turbine valve opening is restricted to prevent overusing of the heat storage, so that the pressure fluctuation cuts down and trends to steady. In short, unidirectional decoupling boiler following coordinated control mode, compared to pure boiler following control mode, has a better control quality.

b) Unidirectional Decoupling Turbine Following (TF) Coordinated Control Mode

This kind of coordinated control mode is based on boiler following control mode and introduces the unit power deviation into turbine controller.

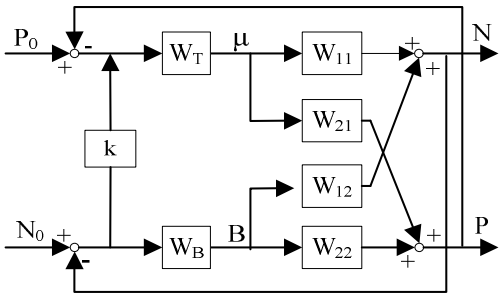

Fig.8 Structure of unidirectional decoupling TF mode

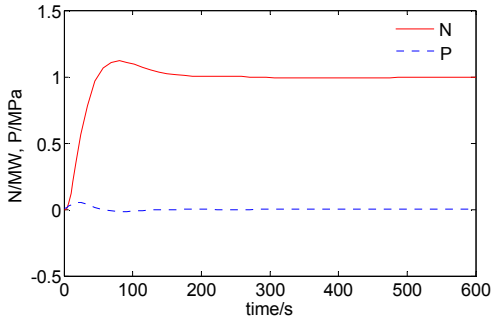

Fig.9 Simulation curves of unidirectional decoupling TF mode

The parameters of turbine PID controller: kp=-11.4264, ki=-0.4963, kd=-5.0507; the parameters of boiler PID controller: kp=1.3632, ki=-0.4963, kd=0.7607; decoupled coefficient: k=0.1.

When load command changed, boiler and turbine controllers both receive the signal to regulate the corresponding actuating mechanism. During the boiler combustion delay period, temporarily

using of boiler heat storage makes the output rapidly response to the unit power command. As Figure 9 shows, unit power reaches the steady value very quickly after first peak; regulation quality is much more improved though the pressure has a little instability.

c) Bidirectional Decoupling Boiler Following (BF) Coordinated Control Mode

The two coordinated control modes mentioned above only realize unidirectional coordinated control, which means that just one of the regulated variables is coordinated controlled by two regulating variables, while the other is still being adjusted by one，so it is relatively simple coordinated control scheme. Integrated coordinated control mode achieves bidirectional coordinated control to get better control effect.

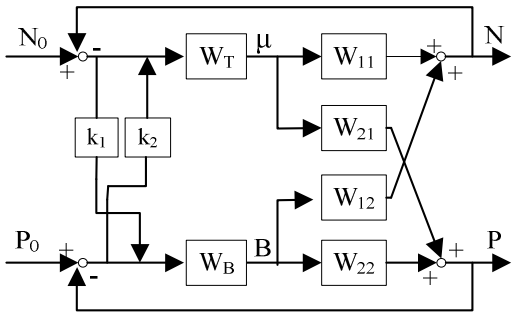

Fig.10 Structure of bidirectional decoupling BF mode

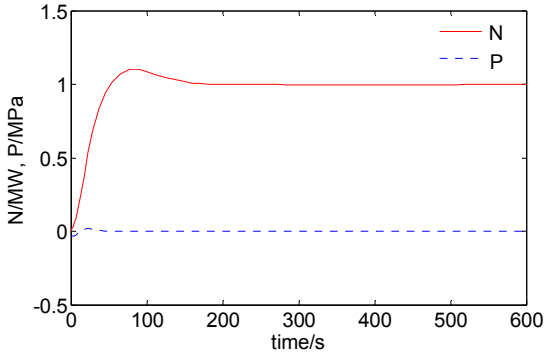

Fig.11 Simulation curves of bidirectional decoupling BF mode

The parameters of turbine PID controller: kp=4.487, ki=0.0578, kd=-0.0037; the parameters of boiler PID controller: kp=15.0545, ki=1.2987, kd=0.0196; decoupled coefficient: k1=0.3619, k2=-50.1625.

The simulation results indicate that the method has a good dynamic performance and curve of output power tracks the set value smoothly and rapidly with smaller overshoot and shorter adjusting time. At the same time, the main steam pressure has little fluctuations descending to the stable value soon.

Conclusions

This paper takes 300MW power plant as the research object, conducting simulation study on 5 kinds of load control mode which are classified as turbine and boiler separate control mode and coordinated boiler-turbine control mode. The simulation experiments show that, under pure boiler following control mode, the main steam pressure fluctuates wildly for power constant-disturbance, is likely to affect the safety of operation; under pure turbine following control mode, output power tracks the set value slowly which has a bad load adaptability[7]; coordinated boiler-turbine control mode combine the best of both, which can not only adapt to changes of the load in power network quickly, but also make the main steam pressure to maintain nearby the rating [8]. Further, the performance of bidirectional decoupling coordinated control mode is better than unidirectional ones. But it also increases the complexity of design and difficulty of regulation.

Keywords: rotary valve, single- spool , double- spool , axial force, torque

Abstract: There is also a monomer leak valve body on the single spool, Leakage between the guide groove affected the layout of the form guide groove. Two end faces of the single spool work in the different fluid pressure in the chamber. When the working pressure of the hydraulic system is high, the pressure differential will cause the spool bearings subject to large axial force. It will increase the resistance torque of bearing rotation. Effects of axial force also limits the increase spool diameter. Double spool valve with two spool rotation series manner. Each spool in the same pressure in the working medium. Eliminating the axial force of the valve body due to fluid pressure differential generated, also reduces the resistance to rotation of the spool moment and the impact of guide groove arrangement by oil leak, and also the commutation frequency of the rotary valve can be improved by increasing the diameter of the spool.

Introduction

We can improve the conversion rate by increasing the rotational speed of the rotary valve or increasing the number of the guide groove to increase the operating frequency of the rotary valve. However, under the current conditions, improving the speed of the rotary valve is limited by speed of drive motor. The rotary valve shaft is increased to increase the number of its circumferential arrangement of the guide groove. And it is necessary to increase the diameter of the rotary valve to increase the number of lead tank. Increasing the diameter of the rotary valve to increase the speed of a method for easily implemented . Increasing the diameter of the rotary valve to increase the commutation speed is the method for easily implemented[1] .

The diameter of rotary valve spool shaft is increased,the axial force acting rotary valve shaft needs to be reduced . The diameter of the spool shaft can be increased to increase the number of the guide groove . While increasing the diameter of the spool shaft but also increases the pressure receiving area of the end face. For this reason we solve the question only from the pressure difference between the working chamber. Select the low viscosity hydraulic oil can reduce the drag torque of the rotary valve . Raise the operating temperature of the hydraulic oil can reduce the viscosity of the hydraulic oil. However, the use temperature of the hydraulic oil is limited . Viscous fluid drag torque calculation formula including the resistance torque of the valve body , thrust bearing rotation resistance torque of the rotary valve to withstand the viscous drag torque[2] :

$$M_2 = M_{21} + M_{22} = C_2 \mu \cdot n \tag{1}$$

Coefficient C only depends on the structure of the rotary valve. K is an additional factor
The total drag torque of the rotary valve is

$$M = M_1 + M_2 = C_1 P + C_2 \mu \cdot n \tag{2}$$

Formula： M_1 is the moment of resistance of the thrust bearing.

The drag torque of the rotary valve is composed of two resistance moment . One resistance torque is caused by the pressure difference, the resistance moment of the Bearing rotation; Another is the moment of resistance caused by fluid viscosity . From equation (2) we can see the resistance of the rotary valve depends on the following factors in three areas

a.The differential pressure of the working chamber of rotary valve spool p

b.speed of the rotary valve spool shaft n

c.Hydraulic oil viscosity.

These three factors determine the drag torque of the rotary valve. The problem of structure designed of the rotary valve is to reduce the pressure differential of working chamber to increase the diameter of the rotary valve and the control of the rotary valve spool drag torque .

Structure and stress analysis of the dual rotary valve spool

Figure 1 is the structure of the dual rotary valve spool .

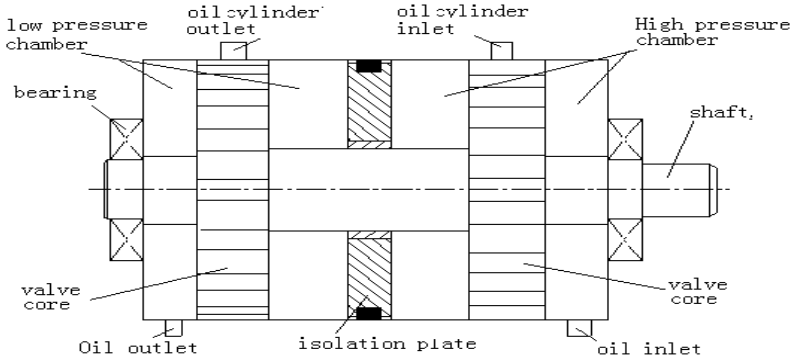

Figure 1.Schematic diagram of dual rotary valve spool

Dual rotary valve spool can be used in two structural forms . one is designed for a body double valve structure . This structure, the rotary valve spool mounted on a shaft. Rotary valve housing into two parts , high-pressure working chamber and low- pressure working chamber .Another structure is the series combination of two rotary valve[3] . Respectively, for the rotary valve and low pressure working chamber working chamber . respectively, for the high-pressure working chamber and a low pressure working chamber .If the two end faces of two pressure if the spool is the same area as the axial force generated by the valve body is equal to zero[4] .

Bearing resistance moment

$$M_1 = Gf_1 \frac{d_1}{2} + Ff_2 \frac{d_2}{2} \tag{3}$$

Formula:G—Weight bearing radial load, turn the valve(N);F—Axial load of the thrust bearing(N); f_1, f_2 —Radial, thrust bearing friction coefficient; d_1, d_2 —Radial, thrust bearing diameter(m)

Since G << F, so the formula (3) the first radial bearing drag torque is negligible.

For the same pressure of the working oil chamber , the pressure difference is zero. I.e., resistance force generated by the axial bearing moment $M_1 = 0$

Fluid viscous drag torque

Figure 2 is a schematic structural view of a valve switch . When the rotary valve work one end thrust bearing races and rolling element bearing ring follows the axis of rotation . Oil resistance consists of three parts moment. when rotating the rotary valve.

The oil resistance moment of gap between the rotary valve spool and housing .

$$M_{21} = 2\pi \cdot \mu \cdot \ell_0 \cdot \frac{R_0^3}{\delta} \cdot \omega \tag{4}$$

Formula： μ- Dynamic viscosity of the oil($N \cdot S / m^2$); ℓ_0 - Rotary valve width(m);

R_0 - The radius of the rotary valve(m); ω- Angular speed of rotation of the rotary valve(rad/s).

Thrust bearing drag torque preventde by the oil between the thrust bearing and valve.

$$M_{22} = 4\pi\mu \cdot \ell_1 \frac{R_1^2 R_2^2}{R_2^2 - R_1^2} \omega \tag{5}$$

Formula： ℓ_1 - Width of the rotating part of the thrust bearing(m).

R_1 - Thrust bearing outer radius(m); R_2 - The valve body bore radius(cm).

The remaining symbolic significance for formula(4).Spool valve body by double rotation suffered very little axial force , without using the thrust bearing , so $M_{22}=0$.

Moment of resistance actioned on the end face of the rotary valve by oil.

This part of the moment of resistance is difficult to quantitatively calculated using the expression represented in the form factor[5] .

Oil for rotary valve rotating moment of resistance.

$M_2 = K(M_{21}+M_{22}) = KM_{21}$

Here K is the coefficient of drag torque considering additional oil on the end face of the rotary valve . The (4) and (5) into too

$$M_2 = \frac{1}{15}\pi^2 \cdot \ell_0 \cdot \frac{R_0^3}{8} K \cdot \mu \cdot n = C_2 \mu \cdot n \tag{6}$$

Formula： C_2 is the amount of the transfer parameters related to the valve arrangement，for specific rotary valve is a constant。

Let: $R_0 = 6\times10^{-2}m$, $\ell_0 = 7\times10^{-2}m$, $\delta = 1\times10^{-4}m$ and $0.5\times10^{-4}m$,K=1.3 Calculated C_2

$\delta = 1\times10^{-4}m$, $C_2 = 1.295\times10^{-1}$. $\delta = 0.5\times10^{-4}m$, $C_2 = 2.588\times10^{-1}$

30 ℃, the dynamic viscosity of the oil

The 20th Oil， $\mu = 5.085\times10^{-2}N\cdot s/m^2$ .The 30th Oil， $\mu = 8.194\times10^{-2}N\cdot s/m^2$.

The rotation speed 300, 600, 1200, 1800 r/min. fluid resistance moment M_2 .

The rotation speed (rpm)			300	600	1200	1800
$M_2(N\cdot m)$	$\delta = 1\times10^{-4}m$ $C_2 = 1.295\times10^{-1}$	The 20th Oil	1.976	3.951	7.902	11.853
		The 30th Oil	3.183	6.367	12.733	19.100
	$\delta = 0.5\times10^{-4}m$ C_2=2.58	The 20th Oil	3.948	7.896	15.792	23.688
		The 30th Oil	6.362	12.724	25.447	38.171

By the formula (6),we can see that the rotation of the rotary valve oil on the oil viscosity and drag torque proportional to the speed of the rotary valve . A gap δ between the rotary valve and the valve body also has a great impact on M_2, the smaller δ and the larger M_2.

Conclusion

Rotary valve with dual valve structure, The two end faces of the valve body fluid pressure at the same area. Axial force in the same conditions spool end area of the hydraulic force generated by zero . Rotary valve spool shaft supporting structure can no longer install the thrust bearing . Drag torque thrust bearing axial force caused disappeared.

Dual rotary valve spool drag torque effects by the oil viscosity as the same as the single rotary valve spool. Oil viscosity is the same, the spool speed increased, the resistance of the rotary valve torque increases. Under conditions of constant temperature rotary valve speed is only proportional to the resistance moment

Each double valve body fluid pressure in the working chamber type , the guide groove may be slotted through the peripheral surface of the spool . High and low pressure working chamber lead tank will not leak between them.

Because the dual spool axial force of the rotary valve can be eliminated , and therefore the diameter of the valve body of the rotary valve can be designed to be larger. This can increase the number of the guide groove of the valve body , for the rotary valve to increase the frequency.

Computing Method of Auto-rotated Precision Index of Gun Barrel Based on Exterior Ballistic Computation

Yang Yadong[a], Ma Jisheng, Jia Changzhi
Ordnance Engineering College, Shijiazhuang 050003, China
422677012@qq.com

Keywords: Auto-rotated precision of gun barrel, Polynomial fit, External ballistics, Firing table

Abstract: Auto-rotated precision of gun barrel is a key operation of firing, and the research of its testing method should depend on its index computing. According to discrete value in the firing table and the exterior ballistic computation based on least square polynomial fit method, the mapping function between battle sight and range dispersion was confirmed. And by analyzing the effect of offset induced by auto-rotated precision of gun barrel, the index function which could offer a data origination for the verification of testing method of auto-rotated precision of gun barrel was provided.

Introduction

A self-propelled artillery functioned a gun barrel auto-rotated system has the preemption capability of firing by saving battery time. However, gun barrel auto-rotated system always consists of complicated electromechanical devices each operating error of which may induce the offset of sophisticated shooting. The most critical piece is whether the operation effect of gun barrel auto-rotating system match the data in the elevation table. Accordingly, it is indispensable to check the error of auto-rotating precision which decided the elevation prediction correction.

The gun barrel rotated precision was used to detecting by computing the difference of angular height and firing azimuth between fore-and-aft gun barrel rotated with the device theodolite or total station apparatus[1-4]. This technique take the advantage of theodolite and total station apparatus with high-accuracy measuring, high universality and low cost, but it is intricate to operate for the operation must be finished by team working of *3* to *5* manipulators. Also with the disposition request, this technique should be finished in the well geographical environment. The optical fiber gyroscope and laser gyroscope were mentioned in some papers to be used to detect the parametric detection of firing control system which may be a good idea to actualize the detection of gun barrel rotated precision[4,5]. However, for the inherent attribute of transducer, investigators have to remodeling and testing ceaselessly to solve the problem of measurement accuracy, zero drift, definition etc. And to all the detecting technique, the criterion of the determination data should be first confirmed.

This paper compute the exterior ballistic by fitting the discrete value in the firing table based on least square polynomial fit method. By studying the mapping relationship of gun battle sight and range of fire, the auto-rotated precision index function was put forward which could be used as the criterion of the determination data of auto-rotated precision of gun barrel.

Analysis of exterior ballistic computation method

Exterior ballistic computation can be divided into the approximate solution type and the exact solution type which include ballistic table computation method and numerical integration method. To the ballistic table computation method, computation of ballistic data is actualized by direct selection or calculus of interpolation based on the discrete value in the firing table. To the numerical integration method, computation of ballistic data is acquired from the trajectory equation computation, it is always actualized by step-by-step integration based on fourth-order Runge-Kutta method or Adams algorithm. Both of these two method take the disadvantage of cannot give the

descriptive mathematics model of firing data. The approximate solution type of exterior ballistic computation which could describe mathematics model of firing data whereas take the disadvantage of relative high accumulated error is computing the integral quantity of exterior ballistic directly in the restrictive conditions[6].

According to the advantage and disadvantage of above exterior ballistic computation method, this paper compute the exterior ballistic by fitting the discrete value in the firing table based on the least square polynomial fit method which could give the descriptive mathematics model of firing data and have a relative low computation error at the same time.

Used the battle sight and its correspondent discrete value in the firing table.Hypothesize the polynomial fitting function as:

$$X = a_0 + a_1\theta + ... + a_m\theta^m = \sum_{j=0}^{m} a_j\theta^j \qquad (m < n) \tag{1}$$

And construct the error sum of squares function as:

$$F(a_0, a_1, ..., a_m) = \sum_{i=1}^{n} \left(X - X_i \right)^2 \tag{2}$$

Compute the partial derivative of the multinomial coefficient a_0，a_1，…，a_m，and make a_0=a_1=…=a_m=0, then

$$\frac{\partial F}{\partial a_j} = 2\sum_{i=1}^{n} \left(X - X_i \right)\theta_i^j = 0 \qquad j = 0,1,...,m \tag{3}$$

It means

$$a_0\sum_{i=1}^{n}\theta_i^j + a_1\sum_{i=1}^{n}\theta_i^{j+1} + ... + a_m\sum_{i=1}^{n}\theta_i^{j+m} = \sum_{i=1}^{n} X_i\theta_i^j \qquad j=0，1，2，…，m \tag{4}$$

In this function, the coefficient is a positive definite symmetric matrix which means a_0，a_1，. . . ，a_m have a unique solution, and according to the solution, the least square polynomial by fitting the discrete data of θ_i and X_i can be actualized.

Polynomial evaluation

It is necessary to do segmented approximation in the exterior ballistic fit based on least square polynomial fit zconfirmed to use *4* degree polynomial and the high-angle firing trajectory was confirmed to use *5* degree polynomial to fit. And in the simulation, there comes the problem that when the degree was greater than *3*, the higher-degree polynomial coefficient was minor which may be regard as *0* in the computational process. And it is effective to use the normalization method to avoid this problem.

According to the results of least square polynomial fit, in this specified firing condition, the average error of the flat trajectory, the bending trajectory and the high-angle firing trajectory was separate *0.20m*, *1.40m* and *2.55m*. Obviously, the average error satisfied the precision request. Figure*1* ~ figure*4* showed the results of *3* separate trajectory and the exterior ballistic.

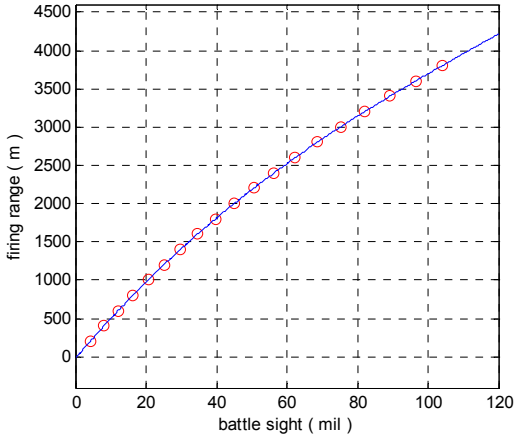

Figure1 Fitting result of flat trajectory

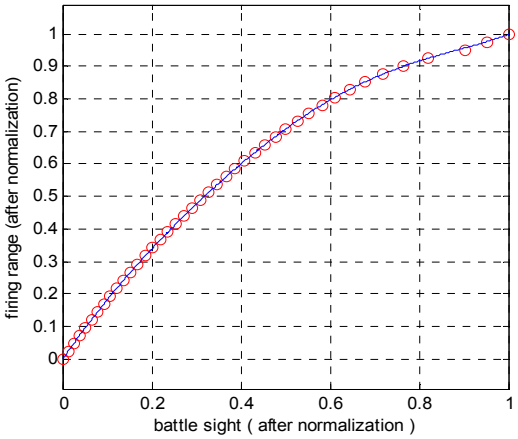

Figure2 Fitting result of bending trajectory

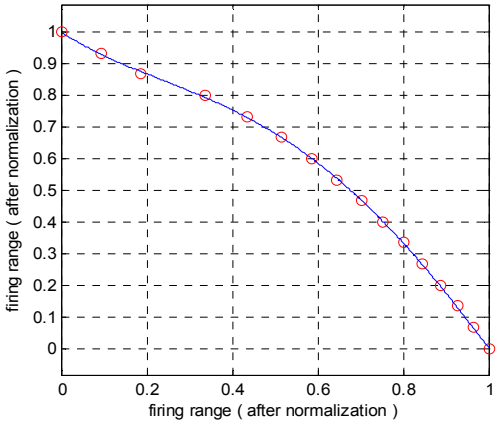

Figure3 Fitting result of high-angle firing trajectory

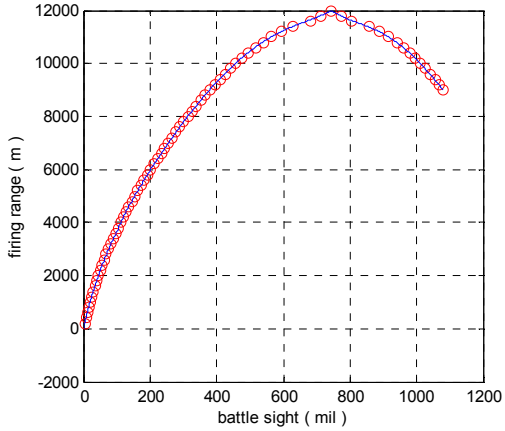

Figure4 Fitting result of exterior ballistic

Analysis of rotated precision index of gun barrel

Hypothesize θ as specified battle sight, $X(\theta)$ as the correspondent firing range and h as rotated precision, the dispersion error induced by rotated precision could be described as:

$$F(\theta,h)=X(\theta+h)-X(\theta) \qquad \theta+h\le 1080 \tag{5}$$

And

(1) To the flat trajectory:

$$F(\theta,h)=0.0018h\theta^2+\left(0.0018h^2-0.4678h\right)\theta+(0.0006h^3+54.1111h),\quad \theta+h\le 104.1 \tag{6}$$

The partial derivative to θ $\dfrac{\partial F(\theta,h)}{\partial\theta}<0$.

According to the fitting result, the dispersion error induced by rotated precision have the maximum error value in the starting point of curve. Therefore, to flat trajectory, when the rotated precision was h, the maximum error value of rotated precision was:

$$F(4.2,h)=0.0006h^3+0.00936h^2+52.1465h \tag{7}$$

(2) To the bending trajectory:

$$F(\theta,h)=8200\times\left\{2.0304\frac{h}{644.1}-2.2864\left[\left(\frac{\theta-104.1+h}{640}\right)^2-\left(\frac{\theta-104.1}{640}\right)^2\right]+3.9742\left[\left(\frac{\theta-104.1+h}{640}\right)^3-\left(\frac{\theta-104.1}{640}\right)^3\right]-4.7343\left[\left(\frac{\theta-104.1+h}{640}\right)^4-\left(\frac{\theta-104.1}{640}\right)^4\right]+2.0152\left[\left(\frac{\theta-104.1+h}{640}\right)^5-\left(\frac{\theta-104.1}{640}\right)^5\right]\right\} \quad 104.1<\theta+h\le 744.1 \tag{8}$$

The partial derivative to θ was also less than *0,* and of course its higher term could be neglected. Similarly as the flat trajectory, the dispersion error induced by rotated precision have the maximum error value in the starting point of curve. And after linearization, when the rotated precision was h,

the maximum error value of rotated precision was：

$$F(h) \approx 25.9h \tag{9}$$

(3) To the high-angle firing trajectory:

$$F(\theta,h)=3000\times\left\{-\frac{0.8753h}{335.9}+1.5860\left[\left(\frac{\theta-744.1+h}{335.9}\right)^2-\left(\frac{\theta-744.1}{335.9}\right)^2\right]-2.7504\left[\left(\frac{\theta-744.1+h}{335.9}\right)^3-\left(\frac{\theta-744.1}{335.9}\right)^3\right]\right.$$
$$\left.+1.0432\left[\left(\frac{\theta-744.1+h}{335.9}\right)^4-\left(\frac{\theta-744.1}{335.9}\right)^4\right]\right\} \quad 744.1<\theta+h\le 1080 \tag{10}$$

It means the dispersion error induced by rotated precision have the maximum error value when the firing range was the maximum. Also according to the linearization method, when the rotated precision was h, the maximum error value of rotated precision was:

$$F(h) \approx 16.0h \tag{11}$$

Consequently，in the condition of project the burst cartridge with normal charge in standard ballistic condition, the rotated precision index of gun barrel could be summarized as：

$$F(h)=\begin{cases}52.1h & 4.2<\theta\le 104.1\\ 25.9h & 104.1<\theta\le 744.1\\ 16.0h & 744.1<\theta\le 1080\end{cases} \tag{12}$$

According to the above function, it could be concluded that the least square polynomial fit method can be used to compute the rotated precision index of gun barrel after contrasting the result with the firing table (the maximum error of the flat trajectory, the bending trajectory and the high-angle firing trajectory induced by *00-01mil* firing range was separate *52.0m*, *26.0m* and *17.0m*[7]).

Therefore, based on least square polynomial fit method, the rotated precision index of gun barrel in the other conditions can also be computed. For example, the rotated precision index of gun barrel in conditions of 1500m altitude and project the burst cartridge with normal charge was:

$$F(h)=\begin{cases}53.4h & 4.1<\theta\le 100.0\\ 27.8h & 100.0<\theta\le 705.0\\ 18.1h & 705.0<\theta\le 1080\end{cases} \tag{13}$$

For contrasting the influence of difference of rotated precision index of gun barrel in the different conditions, this paper computed the rotated precision index of gun barrel in *1500m* altitude and *0m* altitude using normal charge which was shown in figure *5,* also the rotated precision index of gun barrel in conditions of project the burst cartridge with normal charge and *1#* zone charge in *0m* altitude was shown in figure*6*. In the two figures, the x axis was the rotated precision index of gun barrel, the y axis was the range sight, the z axis was the error value.

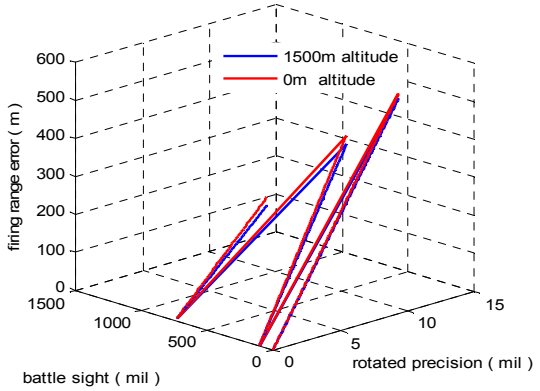

Figure5 Index function of rotated precision in different altitude

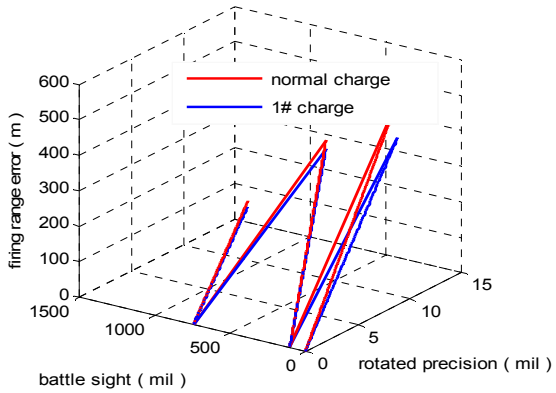

Figure6 Index function of rotated precision in different charge

There comes the result that along with the increase of charge and altitude, the coefficient of rotated precision index of gun barrel increased according to curves in figure *5* and figure *6*.

Therefore, in the firing table, the condition of maximum charge and *1500m* altitude was the extremal condition which can be used to compute the rotated precision index of gun barrel. And the maximum rotated precision index of gun barrel of the flat trajectory, the bending trajectory and the high-angle firing trajectory induced by *00-01mil* firing range was separate *53.4m*, *27.8m* and *18.1m*.

Conclusion

The mapping function of battle sight and firing range was computed based on least square polynomial fit method according to the data in the firing table in this paper, also it put forward these conclusions list next.

(1) The exterior ballistics should be divided into flat trajectory, bending trajectory and high-angle firing trajectory to be used to fit based on least polynomial fit method, and this piecewise fitting technique takes the advantage of high accuracy.

(2) Along with the increase of charge and altitude, the coefficient of rotated precision index of gun barrel increased, so it is necessary to select the high altitude and maximum charge condition to be used to compute the rotated precision index of gun barrel.

(3) The dispersion induced by rotated precision of gun barrel include the distance dispersion and direction dispersion, and the computed result put forward in this paper was based on distance dispersion that induced by rotated precision of gun barrel. So when used as the criterion of the determination data of auto-rotated precision of gun barrel, the direction dispersion induced by rotated precision of gun barrel should also be taken into account, and of course the least square polynomial fit method could be tried to accomplish the study.

Keywords: Plug-in hybrid, Power system, Parameters design, Simulation analysis

Abstract. Based on design requirements of plug-in hybrid vehicle, using the method of theoretical analysis, the parameters matching design of drive motor, engine-generator set, battery, transmission and other subsystems is executed, and modeling and simulation are carried out using AVL-CRUISE software, simulation results show that the design is reasonable, laying a good foundation for the smooth development of the plug-in hybrid vehicle.

Introduction

Compared with hybrid vehicle of Energy conservation type, energy storage system of plug-in hybrid vehicle（PHEV）can be charged on running , and also charged via a power outlet, it can work longer in mode of battery power, for particular distance of daily commute, PHEV can work in mode of pure electromotion, The internal combustion engine provides additional power required by traveling of the long distance, PHEV possesses ability of better using alternative fuels and has wide development prospects in the field of new energy vehicles[1][2]. Compared with the traditional internal combustion engine vehicles, PHEV possesses motor, engine – generator set, battery and many other subsystems, in the early stage of development of PHEV, power, economy and reliability of vehicle can be improved greatly through the accurate design of power system parameters, coordination of subsystem performance and good match[3][4][5].

1. Vehicle parameters and the basic performance requirements

Table 1 Vehicle parameters

Parameter name		Value	Unit
Kerb mass		1200	kg
Gross Mass		1580	kg
Wheel base		2467	mm
Centroid height		500	mm
Frontal area		1.97	m^2
Drag coefficient		0.284	-
Rolling resistance coefficient		0.013	-
Wheel radius	Static radius	287	mm
	Dynamic radius	301	mm

With the continuous development of the drive motor, battery and transmission technology, power performance of electric vehicles ban be comparable to conventional car basically. Combining the

performance characteristic of electric vehicle, according to demand for vehicle performance, the basic parameter and vehicle performance index of PHEV vehicle are shown in Table 1 and Table 2.

Table 2 Performance index of vehicle

Performance requirement	Items	Index
Speed requirement	Maximum speed	≥120 km/h
Acceleration performance	0~50km/h	≤8s
	50~80km/h	≤10s
Climbing performance	Maximum speed when slop is 4%	≥70 km/h
	Maximum speed when slop is 12%	≥40 km/h
	Maximum gradeability	≥20%

2. Parameters design of power system for PHEV

Parameters design of drive motor. Power requirement of PHEV can be obtained by the formula (1), (2) and (3) on three states of maximum speed, acceleration and climbing.

$$P_{e1}=\frac{1}{\eta_T}\left(\frac{mgfu_a}{3600}+\frac{C_D A u_a^3}{21.15\times 3600}\right). \tag{1}$$

$$P_{e2}=\frac{1}{\eta_T}\left(\frac{mgfu_a}{3600}+\frac{C_D A u_a^3}{21.15}+\delta m u_a\frac{du}{dt}\right). \tag{2}$$

$$P_{e3}=\frac{1}{\eta_T}\left(mgf\cos\alpha u_a+\frac{C_D A u_a^3}{21.15}+\mathrm{mg}u_a\sin\alpha\right). \tag{3}$$

Where, η_T is driveline efficiency, m is full load quality, f is rolling resistance coefficient, C_D is air resistance coefficient, A is frontal area, u_a is maximum speed, v is speed, δ is moment of inertia conversion coefficient, α is climbing angle.

Table 3 Estimated data of motor peak power

Performance requirement	Motor power
Maximum speed v_{max} ≥120 km/h	20.88 kW
Acceleration performance 0~50km/h≤7s	49.3 kW
Acceleration performance 50~80km/h≤8s	38.6 kW
Max stable speed of slop of 4%≥70 km/h	19.85 kW
Max stable speed of slop of 12%≥40 m/h	24.93 kW
Maxi stable speed of slop of 20%≥5 km/h	4.83 kW

According to formula (1), (2) and (3), the maximum power demand estimated under kinds of conditions are shown in Table 3.

To meet the power performance, rated power of drive motor must satisfy the power needs of the maximum speed, peak power must meet the need of acceleration performance. From Table 3, the rated power is not less than 20.88kW, peak power of motor is not less than 49.3kW, and the rated power of motor is taken as 25kW, peak power of motor is 50kW.

Permanent magnet drive motor has advantages of high efficiency, high power density, Its working

voltage is 100 ~ 400V, maximum rotational speed is 4000-10000r/min, constant power factor is up to 2.25, drive motor adopts permanent magnet synchronous motor, parameters of drive motor in the design are shown in Table 4.

Table 4 Parameters of drive motor

Parameters	Value
Rated power	25kW
Overloading coefficient	2
Base speed	3000rpm
Motor voltage	324V
Peak power	50kW
Peak torque	160Nm
Peak speed	8000rpm

Parameters design of engine-generator set. In case of sufficient electric quantity PHEV switches off engine, uses electrical energy preferentially, when the electric quantity of power battery drops to a certain extent and power battery can not continue to supply or electrical power provided by battery can not meet the needs of motor, the engine-generator set start work to provide enough power satisfying the needs of vehicle.

To reduce the charge and discharge times of battery and ensure battery safety, in the design, when the state of charge of battery is below 40%, the generator begins work, and it meets the demand of peak power. Design of engine- generator set not only meet the needs of the motor peak power, but also meet engine and generator working located in each area efficient district. Based on the above analysis and match of work area, the parameters of engine and generator determined are shown in Table 5

Table 5 Parameters of engine-generator set

Engine		Generator	
Maximum rotational speed	6000rpm	Maximum rotational speed	6000rpm
Maximum torque / speed	115Nm/4500rpm	Voltage	324
Maximum power	62kW	Maximum power	50 kW
Displacement	1.5L	Peak torque	160Nm

Parameter design of battery pack. The Endurance mileage of pure electromotion has a great influence to cost and application performance of PHEV, here, the endurance mileage of pure electromotion is driving distance when the battery is fully charged and doesn't rely on the engine to recharge. Rated capacity of battery can be obtained by formula (4).

$$W_0 = \frac{P_v S}{0.7 v \eta_m}. \tag{4}$$

Where, W_0 is rated total energy of battery, P_v is motor power traveling with the velocity of v, S is distance traveling with the velocity of v. Rated capacity Q satisfies formula (5).

$$Q = \frac{W_0}{U_B}. \tag{5}$$

Where, Q is rated capacity of battery, U_B is battery voltage.

In the design, PHEV is required traveling 90km with the velocity of 40km/h using pure electric, According to formula (4), battery capacity is obtained as 10.39kwh. According to formula (5), the rated capacity of battery is obtain as 32.07Ah.

Transmission System Design. Speed ratio of transmission system needs follow the requirement of meeting the needs of maximum gradeability and ensuring the desired maximum speed. Gear ratio of transmission is required to satisfy the formula (6) and (7).

$$i_0 \geq \frac{mg(f\cos\alpha_{\max}+\sin\alpha_{\max})r}{T_{\max}\eta_t}. \tag{6}$$

$$i_0 \leq \frac{0.377 n_{\max} r}{v_{\max}}. \tag{7}$$

Where, i_0 is speed ratio of transmission, r is wheel rolling radius, $T_{\max}$ is peak torque of motor, $n_{\max}$ is maximum speed of drive motor. In the design, the value of i_0 is chosen as 7.05.

3. Simulation Analysis

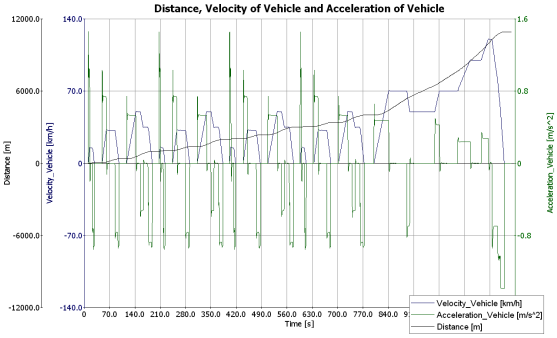

Fig. 1 NEDC condition

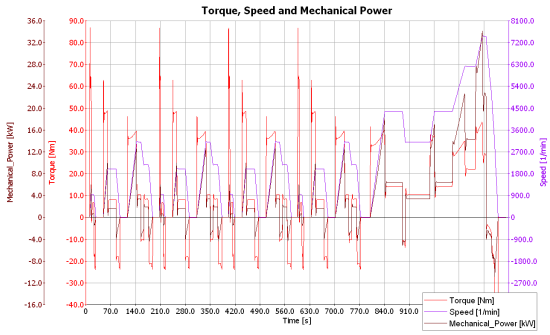

Fig. 2 Working curve of drive motor

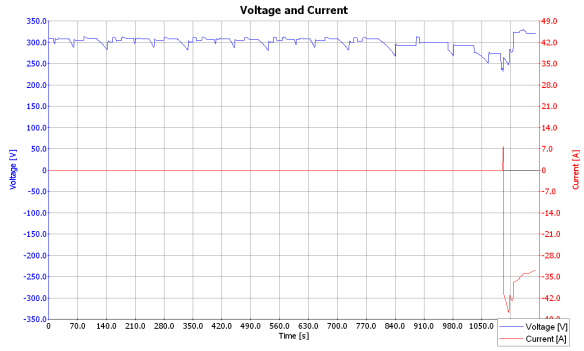

Fig. 3 Working curve engine

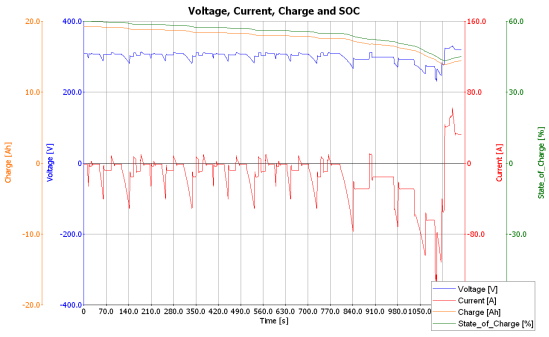

Fig. 4 Working curve of battery

To verify the reasonableness of design, power system of PHEV is simulated using AVL-CRUISE, simulation results under NEDC condition are shown in Fig. 1, Fig. 2 Fig. 3 and Fig. 4.

Table 7 Power performance simulation results

Performance requirement	Item	Simulation result	Reference index
Speed requirement	Maximum speed	128 km/h	≥120 km/h
Acceleration performance	0~50km/h	6.6s	≤7s
	50~80km/h	5.82s	≤8s
Climbing performance	Maximum speed when slop is 4%	128 km/h	≥70 km/h
	Maximum speed when slop is12%	83 km/h	≥40 km/h
	Maximum gradeability	23.8%	≥20%

It can be seen from Fig. 1 to Fig. 4, total mileage is 10.93km under NEDC cycle condition, and duration is 1179.8S, maximum speed is 120.5km/h, maximum acceleration is 1.46m/s^2, maximum deceleration is -0.953 m /s^2. Drive motor works in the range of 2000-7500rpm at most of the time, state of charge of battery is 60% in the beginning, from the beginning of 1100 seconds, the state of charge of battery is approaching 43%, engine–generator set starts automatically, providing power for the drive motor to maintain the normal running of the vehicle, at the same time charging the battery. It can be seen from Table 7, maximum speed of PHEV is 128km/h, acceleration time is 6.6s from 0 to 50 km/h, acceleration time is 5.82s from 50 to 80 km/h, Maximum gradeability is 23.8%, and the power indexes meet design requirements.

4. Conclusion

According to performance index of vehicle, basis on theoretical calculation, the parameter of drive motor, the engine-generator set, battery, transmission system and other subsystems were designed, the vehicle model is built using AVL-CRUISE software, vehicle performance and vehicle power performance under NEDC cycle condition are simulated. Simulation results show that the PHEV designed can meet operation requirements under the NEDC cycle condition, while the maximum speed, climbing performance, acceleration performance meet the design requirements, parameters design of drive motor, the engine–generator set, battery, transmission system and other subsystems is reasonable, it lays a good foundation for the smooth development of the PHEV.

Keywords: micro-spring; parallel spring; eigenvalue buckling analysis; stability

Abstract. Compression deformation will cause a micro-spring to buckle, and structural parameters, constraint conditions and structural forms of a micro-spring will affect its critical load and buckling mode. In order to study the influence on the micro-spring's stability caused by structural forms and find a structure to improve its critical load in the end, this paper designs a new kind of parallel micro-springs, which consists of two same-structured S-shaped planar micro-springs. We have carried on eigenvalue buckling analysis on the parallel micro-spring by software ANSYS, and have gotten its six orders' buckling mode. Because the critical load of the parallel micro-spring may change with the length of the beam connecting the two sub-springs, this paper studies the effect of the beam's length on the parallel micro-spring's critical loads and buckling mode. From comparing the analysis results between parallel micro-spring and single micro-spring with same stiffness, this paper concludes the stability's degree of improvement.

Introduction

Micro-spring is a very important and typical micro-mechanical element, and it is a key part for micro sensors, micro actuators and micro gyroscope. It can provide elastic force for these inertial devices, and transfer energy [1]. Due to differences of micro-mechanical processing technology and conventional processing technology, both structure, size and weight of micro-spring and conventional spring vary a lot. Compared with traditional spring, micro-spring has more kinds of structural forms. The structural form of planar micro-springs is completely different from traditional coil springs. In terms of material mechanics and structural mechanics, planar micro-spring can be seen as planar steel frame, which is connected to each other by elastic beams. Several researchers have studied structural forms, properties and detection methods of planar tensile micro-spring [2-4], however, few has researched properties and design methods of compression micro-spring. In addition, compression deformation will cause a micro-spring to buckle, for micro-springs are almost planar and with thickness of only a few hundred microns. Therefore, theoretical analysis and design method of the stability of micro compression spring should be improved.

U.S. Naval Air Warfare Center has developed an electromagnetic micro-mechanical security system to remove insurance for distributed missile in fuze. The security system is composed of three micro-springs [5]. In normal state, two springs are in a state of pretension to fix two locking pins in insurance position respectively, and sliding block is locked by two locking pins. When the projectile is launched, two locking pins successively leave insurance location, and the slider is moved to positive position. Meanwhile, electromagnet is powered off, and the locking pin clicks into the slider, so that insurance is removed. Paras Chawla in India Tapaer University has designed a RF micro-mechanical switch [6]. In this design, mechanical operation of RF switch mainly depends on stiffness coefficient of micro-spring K, which adopts the "bow" shape in order to reduce the stiffness coefficient. H. F. Lin and H. T. in the thirteenth Research Institute of China Electronic Technology Group Corporation have designed a kind of universal micro-mechanical collision switch [7]. The switch is composed of four symmetrically-distributed micro-springs, mass block, collision steps and collision step bottom. When the whole structure is impacted along any direction in XY plane, mass block contacts collision steps and signal is conducted; when the whole structure is impacted along Z direction, mass block contacts the bottom and signal is conducted.

Micro-springs in the switch have three modes of action, which is not only the pure tensile or compressive movement. From above micro-springs' applications in various fields, we can see that as an element of transferring force or energy, micro-spring not only produces tensile deformation, but also develops compression deformation in some applications. So it is necessary to study the stability and deformation characteristics of compression micro-spring.

Z. Wang in Beijing Institute of Technology has researched the influence of S-shaped micro-spring's structural parameters on buckling stability. By optimizing micro-spring's structural parameters on condition of satisfying spring stiffness, she concludes that the critical buckling pressure of optimized structural parameters' micro-spring is increased by 126.8% than that of primary micro-spring [8]. The authors have researched the influence of S-shaped micro-spring's constraint on buckling stability, and find that the critical buckling pressure of micro-spring is increased by 32.2% by adding constraints in X direction. The factors influencing micro-springs' structural stability contain structural parameters, constraints and structural forms. Therefore, we study the effect of parallel micro-spring satisfying stiffness conditions on critical load and buckling mode.

Stability Analysis of Micro-spring

Planar micro-spring has different kinds of structural shapes, such as S shape, W shape, Z shape, the Great Wall shape and L shape. This paper mainly studies the S-shaped planar micro-spring. Compression deformation will cause a micro-spring to buckle. Micro-spring stable failure generally can be divided into equilibrium bifurcation instability and extreme point buckling. In order to research the influence of S-shaped micro-spring's structural form on stability, we ignore the influence of internal defects, and adopt eigenvalue buckling analysis to evaluate the buckling stability of micro-spring.

Firstly, we determine the micro-spring's structural parameters, model and export the spring model's parasolid file by software UG. The spring model is shown in Fig. 1. Secondly, we import model file, carry out buckling analysis and get the critical buckling pressure by software ANSYS. The general process of ANSYS analysis is shown in Fig. 2.

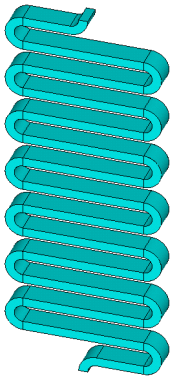

Fig. 1 The spring model

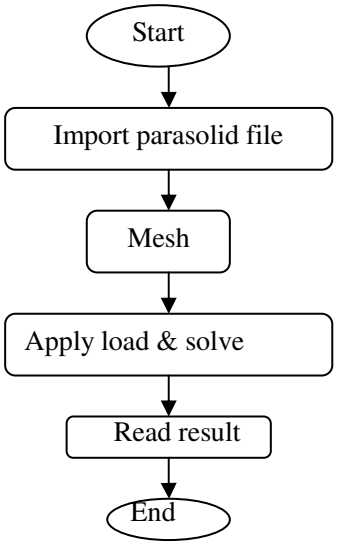

Fig. 2 General process of ANSYS analysis

Analysis Methods

In order to study the improvement level of parallel micro-spring on the stability, we conduct eigenvalue buckling analysis by software ANSYS. The parallel spring and S-shaped planar micro-spring, with the same spring stiffness, are analyzed.

Structural Parameters' Design. Structures of micro-springs are shown in Fig. 3, where a) is the structure of S-shaped plane micro-spring, and b) is the structure of the parallel spring. S-shaped

planar micro-spring can be described by five parameters: number of units *n*, thickness of micro-spring *h*, straight beam width *w,* width of section *b* and inside bend radius *r*, as shown in Fig. 4 a). The parallel spring can be described by the above five parameters and the distance between the two sub-springs *L*, as shown in Fig. 4 b). There are mainly three kinds of working modes: axial deformation, radial deformation and normal deformation. The relationship between S-shaped micro-spring's parameters and elastic stiffness in three working modes are worked out and calculation formula of spring stiffness is

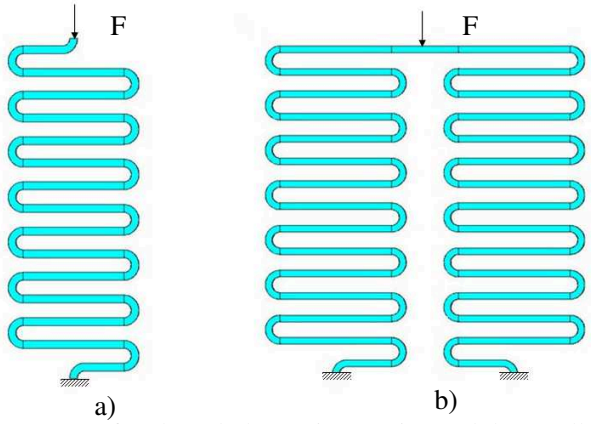

Fig. 3 Structures of S-shaped plane micro-spring and the parallel spring

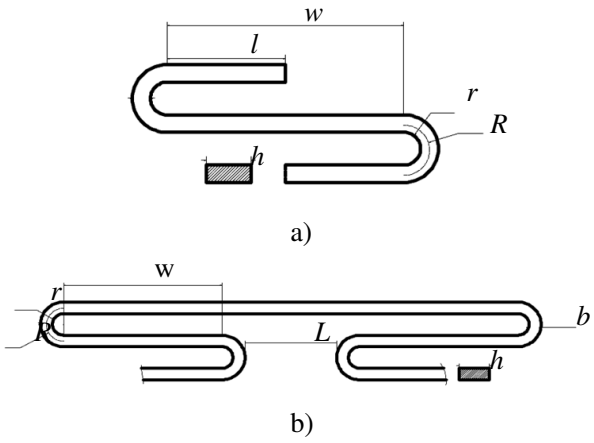

Fig. 4 Structure parameters of S-shaped plane micro-spring and the parallel spring

derived [9]. This paper mainly studies the influence of S-shaped micro-spring in the axial deformation mode on the stability. In the mode of axial deformation, stiffness coefficient of S-shaped micro-spring k is given by Eq. 1.

$$k = \frac{b^3 hE}{n\left[16l^3 + 12R\left(2l^2\pi + 8lR + R^2\pi\right)\right]} \tag{1}$$

where $l = \frac{w}{2}$, $R = r + \frac{b}{2}$, E is the young's modulus of elasticity, n is number of units, h is thickness of micro-spring, b is width of section, l is half of straight beam width w and R is arc radius. The values of S-shaped micro-spring parameters are shown in Table 1. According to Eq. 1, stiffness coefficient of the S-shaped micro-spring k_0 is 448.2534N/m.

Stiffness coefficient of the parallel springs is the sum of each spring stiffness coefficients. Therefore, to make the stiffness coefficients of the parallel spring and S-shaped planer micro-spring mentioned above equal , stiffness coefficient of the parallel spring is supposed to be half of stiffness

coefficient of the S-shaped micro-spring k_0, namely $k1 = ko / 2$.On condition of unchanging *r, w, h, n*, and *E*, only change *b* to fulfill the equation $k1 = ko / 2$.Through calculation, the width of section of parallel spring *b* should be 62μm, which can satisfy that stiffness coefficient of the parallel spring is equal to that of the S-shaped planar micro-spring. Parameter values of S-shaped planar micro-spring and parallel spring are shown in Table 1.

Table 1 Parameter values of S-shaped plane micro-spring and parallel spring

Parameters	Value	Value
Straight beam width *w* [μm]	1060	1060
Inside bend radius *r* [μm]	75	75
Width of section *b* [μm]	80	62
Thickness of micro-spring *h* [μm]	200	200
Number of units *n*	7	7
Young's modulus of elasticity *E* [GPa]	170	170
Poisson ratio *v*	0.3	0.3
Number of S-shaped micro-springs *m*	1	2

Eigenvalue Buckling Analysis. To study improvement level of parallel micro-spring on the stability, both load and constraint of S-shaped plane micro-spring and parallel spring should be the same in the buckling analysis. All degrees of freedom of the bottom of micro-spring are constrained and force F of 1N along the opposite Y axis is applied on the centre of micro-spring top surface, as shown in Fig. 3.

Although the distance between these two springs constituting the parallel spring *L* has no effect on spring stiffness, it does affect the spring buckling stability. Therefore, when *L* changes from 0.1mm to 2mm, eigenvalue buckling analysis of parallel spring is done, and buckling mode is expanded to six orders.

Results and Discussion

Six orders' buckling modal deformation diagrams are shown in Fig. 5, where a) is the deformation of S-shaped planar micro-spring, and b) is the deformation of parallel micro-spring. We can see that the buckling modes of these two kinds of springs have different deformation directions and sequences.

As shown in Fig. 6, the blue solid curve P1 and the green hollow curve P2 respectively show the first-order and second-order critical buckling pressure of the parallel micro-spring with the distance between the two sub-springs *L,* and the thick black line S1 and the thin red line S2 respectively show the first-order and second-order buckling pressure value of the S-shaped planar micro-spring. We can conclude that with the value of *L* increasing, the first-order critical buckling pressure of the parallel micro-spring decreases slowly, while the second-order buckling pressure of the parallel micro-spring increases greatly. The first-order and second-order critical buckling pressure of the parallel micro-spring are both significantly increased than the first-order and second-order buckling pressure of the S-shaped planar micro-spring.

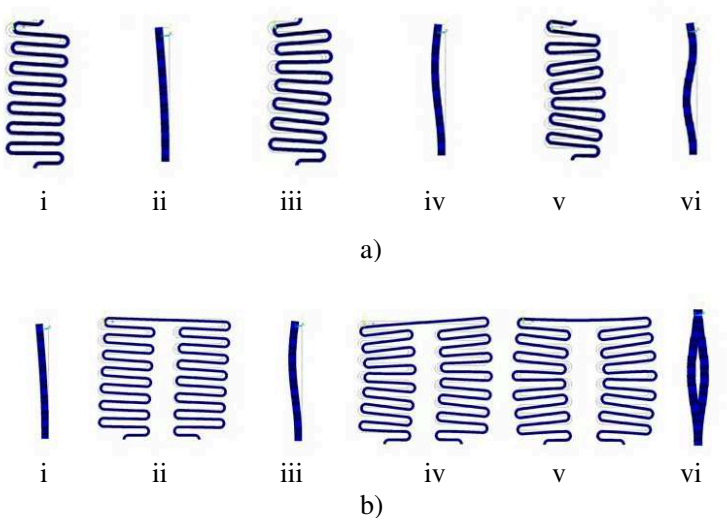

Fig. 5 Six-order buckling modes deformation diagram of S-shaped planar micro-spring and parallel micro-spring

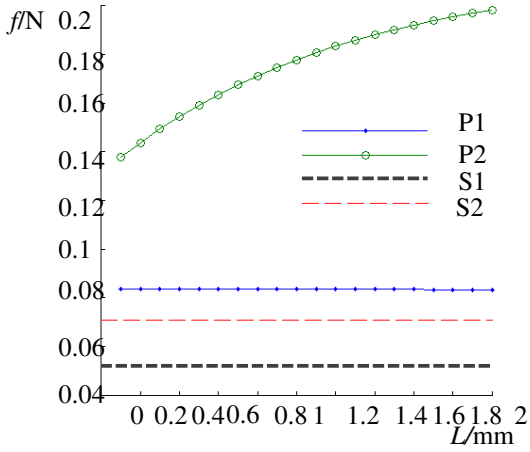

Fig. 6 The first-order and second-order buckling pressure curve of the parallel micro-spring and S-shaped planar micro-spring

Conclusions

This paper designs a parallel micro-spring based on two sub single S-shaped planar micro-springs. In order to research the stability's degree of improvement of the new type of micro-spring, this paper builds FEA model for the parallel spring and the single spring, and the two types of spring have same stiffness. From changing the length L of the beam connecting the two sub-springs, critical load and buckling mode will also change. This paper obtains two curves which respectively show the first-order critical load and second-order critical load with the length L. From comparing the analysis results between the parallel micro-spring and the single micro-spring with the same stiffness, we can conclude that the parallel micro-spring improves the stability significantly. When L is 0.1mm, the parallel spring's first-order critical load is increased by 60% than the single spring, and the second-order critical load is increased by 94.8%. With the increase of the length L, the first order critical load decreases slowly and the second order critical load increases quickly. In the future, another structural form which can improve spring's stability will be carried out.

Passivity-Based Control of Motor for Reaction Wheel

Renlong Yu[a], Jing Jin[b]

Department of control science and engineering in school of astronautics, HIT, China

[a]yurenlong@hotmail.com, [b]jinjinghit@hit.edu.cn

Keywords: Magnetically suspended reaction wheel, passivity-based control, permanent magnetic brushless DC motor, speed mode

Abstract: To achieve high-precision tracking control of motor speed for magnetically suspended reaction wheel, mathematical model combining BUCK converter with permanent magnet brushless DC motor system is established, and a MSRFW speed mode Passivity-based control method is presented. A passivity-based controller of speed tracking is designed in order to enhance the speed of tracking performance. Experiments on MSRW platform show that passivity-based control method can improve the speed of the dynamic response and tracking accuracy, from which the validity is verified.

Introduction

Brushless DC motor (BLDCM) has been widely used in aerospace inertial actuator because of its fast response, high power density, high reliability and maintenance-free. The complexity is evident in the development of a torque/speed regulator. Using d-q transformation to ease the complexity of analyzing three phase motor may serve to design an adequate controller. However, development of a controller based on the transformation of the a-b-c equations to the d-q variables is only advantage for permanent magnet motor with sinusoidal back EMF. Applying the d-q transformation to a trapezoidal back EMF motor can not eliminate the angle dependent phase inductance. The author in Ref.1 applied the d-q transformation to a BLDCM by fixing the synchronous reference frame to the instantaneous rotor flux linkage instead of the rotor geometric axis. However, this approach is cumbersome since the instantaneous rotor flux linkage must be found experimentally and programmed into a digital signal processor. Sliding mode control technique has been proved to be computational extensively when self-adaptive parameter estimation is used to estimate load parameters 2,3. Hysteresis current control and pulse-width modulation (PWM) control coupled with continuous control theory produce the most widely used BLDCM control techniques 4,5. Hysteresis current control is essential toward achieving adequate servo performance 6, namely instantaneously torque response yielding faster speed response compared with PWM control. For most applications, a proportional-integral current and speed compensators are sufficient to establish a well-regulated speed/torque controller. In other cases, a state feedback control is needed to achieve more precise control of the BLDC motor.

To achieve high-precision tracking control of motor speed for magnetically suspended reaction wheel(MSRW), a MSRW speed mode Passivity-based control method is presented based on the established BUCK converter and permanent magnet BLDCM system combining with mathematical model. Passivity-based controller of speed tracking is designed in order to enhance the speed of tracking performance targets. Experiments on MSRW platform show that passivity-based control method can improve the speed of the dynamic response and tracking accuracy, from which the validity is verified.

Mathematical model

Consider a permanent magnet BLDCM for MSRW with its armature circuit loaded into a buck type DC-DC converter, which is shown in Fig.1.

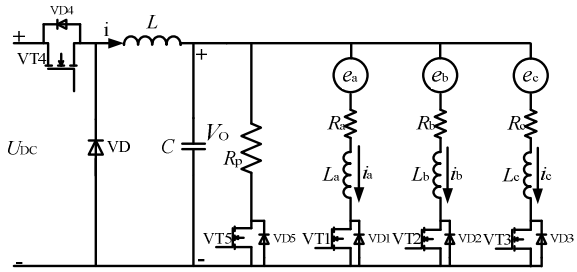

Fig.1 Schematic diagram of reaction wheel motor drive system

Assume that three phase of motor is symmetry, namely L_a-M_a=L_b-M_b= L_c-M_c=L_m , R_a=R_b=R_c=R_m, influence of commutation is omitted.Such a configuration constitutes a tetrad quadrant speed control for a BLDCM drive. The mathematical model of the composite system can be expressed by:

$$\begin{cases} L\dfrac{di}{dt} = -v + Eu \\ C\dfrac{dv}{dt} = i - i_a \\ L_m\dfrac{di_a}{dt} = v - R_m i_a - K_e\omega \\ J\dfrac{d\omega}{dt} = -B\omega + K_m i_a + T_p \end{cases} \tag{1}$$

where i is the input current of buck converter, v the output voltage of buck converter, i_a the BL DCM armature current, ω the speed of motor, T_p the torque perturbation which is assumed to be zer o. The control input is represented by the variable u, which represents a switch position taking value s 0 or 1. The system is controllable and flat because it is linear system with the typical form compos ed of four 1-order deferential equations.

Passivity based controller

A fundamental design idea for the feedback passivity based controller of reaction wheel motor is introduced. The control design method is known as the energy shaping and damping injection method [7,8].

Let the stored energy function of the system and its gradient vector be given as

$$H = \frac{1}{2}x\begin{pmatrix} L & 0 & 0 & 0 \\ 0 & C & 0 & 0 \\ 0 & 0 & L_m & 0 \\ 0 & 0 & 0 & J \end{pmatrix}x^T \tag{2}$$

$$H = \frac{1}{2}\left(Li^2 + L_m i_a^2 + Cv^2 + J\omega^2\right) \tag{3}$$

$$\frac{\partial H}{\partial x} = \begin{pmatrix} Li & Cv & L_m i_a & J\omega \end{pmatrix}^T \tag{4}$$

Then, consider the following Generalized Hamiltonian Canonical representation of the reaction wheel motor system[9,10]:

$$\begin{cases} \dot{x} = (M+N)\dfrac{\partial H(x)}{\partial x} + gu \\ y = h(x) = i \end{cases} \tag{5}$$

Where $M=\begin{pmatrix} 0 & -\frac{1}{CL} & 0 & 0 \\ \frac{1}{CL} & 0 & -\frac{1}{CL_m} & 0 \\ 0 & \frac{1}{CL_m} & 0 & -\frac{K_e}{JL_m} \\ 0 & 0 & \frac{K_m}{JL_m} & 0 \end{pmatrix}$, $N=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -\frac{R_m}{L_m^2} & 0 \\ 0 & 0 & 0 & -\frac{B}{J^2} \end{pmatrix}$, $g=\begin{pmatrix} \frac{E}{L} \\ 0 \\ 0 \\ 0 \end{pmatrix}$, $M+M^T=0$, $N=N^T$

Using the energy shaping and damping injection method to design a dynamic output feedback controller. Consider the following energy function for the tracking error $e=x-x^*(t)$

$$H_e\left(x-x^*\right)=\frac{1}{2}\left(x-x^*\right)^T\begin{pmatrix} L & 0 & 0 & 0 \\ 0 & C & 0 & 0 \\ 0 & 0 & L_m & 0 \\ 0 & 0 & 0 & J \end{pmatrix}\left(x-x^*\right) \tag{6}$$

The function $H_e(x-x^*)$ is a positive definite function and $H_d(x-x^*)$ denotes the following time derivative:

$$\dot{H}_e\left(x-x^*\right)=\left(x-x^*\right)^T\begin{pmatrix} L & 0 & 0 & 0 \\ 0 & C & 0 & 0 \\ 0 & 0 & L_m & 0 \\ 0 & 0 & 0 & J \end{pmatrix}\left(\dot{x}-\dot{x}^*\right) \tag{7}$$

Letting the reference state trajectory be generated by the dynamic system:

$$x^*=M\frac{\partial H\left(x^*\right)}{\partial x^*}+N\frac{\partial H\left(x^*\right)}{\partial x^*}+gu-N_d\frac{\partial H\left(x-x^*\right)}{\partial\left(x-x^*\right)} \tag{8}$$

$$\dot{e}=M\frac{\partial H(e)}{\partial e}+\left(N+N_d\right)\frac{\partial H(e)}{\partial(e)} \tag{9}$$

Finally, equation(12) becomes

$$\dot{H}_e(e)=\frac{\partial H(e)}{\partial e^T}\dot{e}=\frac{\partial H(e)}{\partial e^T}M\frac{\partial H(e)}{\partial e}+\frac{\partial H(e)}{\partial e^T}(N+N_d)\frac{\partial H(e)}{\partial e}$$

Thus,

$$\dot{H}_e\left(e\right)=-R_mL_me_{i_a}^2-BJ\omega<0 \tag{10}$$

We can obtain the dynamical feedback controller expression for the average input using the exogenous system equations and solution for the average control input u which is denoted by u_{av}.

$$u_{av}=\frac{L}{E}\left[\frac{d}{dt}\left(i^*\right)+\frac{v^*}{L}\right] \tag{11}$$

Experimental results

The experimental results of passivity based control are shown in the following. The ratings of the motor are described in Table 1, and the controller is implemented on a TI DSP TMS320F2812 digital signal processor. TMS320F2812 is a high-performance micro-controller designed for high-speed calculation and is equipped with many on-chip peripherals for motor control applications. The ADC unit built-in on the DSP is used to read the feedback current signal. The on-chip general purpose I/O and the capture units on the DSP are applied to capture signals of Hall sensor to generate precise firing commands for the power stage and calculate the motor speed. The PWM unit of the DSP creates the corresponding PWM waveform to drive the wheel motor according to the control command specified by the passivity based controller. A power stage block is used to provide a variable voltage source in driving the wheel motor, and there is a current sensor in this block to measure the fed current of motor. There is also a protection circuit block to protect the DSP from the high voltage and current from the power block.

Table 1 Important parameters

Specifications	Units	Specifications	Units
Number of poles	8	Phase resistance, R_m	1.2Ω

Conclusions

The paper establishes mathematical model combining with BUCK converter and permanent magnet BLDCM and presents a passivity-based control method for MSRW speed mode. In order to enhance the speed of tracking performance targets, passivity-based controller of speed tracking is designed. Experiments on MSRW platform show that the proposed method can improve the speed of the dynamic response and tracking accuracy.

Keywords: the shell; elastic-plastic mechanics; ANSYS; APDL; The optimization design system.

Abstract. In this paper, the shell's strength and stiffness is calculated according to the theory of elastic mechanics and elastic-plastic mechanics theory.And the analysis of the ANSYS software verify the reliability of the theoretical calculation . Using ANSYS parameter design language (APDL)and the optimized design module of ANSYS,the author studies Material nonlinear static analysis ,and establish the parametric analysis program.

Introduction

With the rapid development of coal industry in our country,the design of the explosion-proof electrical equipment should be not only economic and reliable but also convenient .Therefore, it is necessary to conduct Elastic-plastic nonlinear finite element analysis In designing and calculating the shell， and establish the parametric analysis program[1].

The flame-proof principle of explosion-proof enclosure. According to the flame-proof enclosures "d" protection of the equipment in the explosive environment(GB_3836[1].2-2010 ）.Explosion-proof electrical equipment shell can withstand the internal explosive mixture explosion ,and don't be damaged .Don't cause external explosive gas environment lit[2].In other words,explosion-proof enclosure has a certain resistance to blast and flame-proof sex.the main reason of failure is the low material intensity or rigidity.

The following example illustrates Shell analysis optimization process.

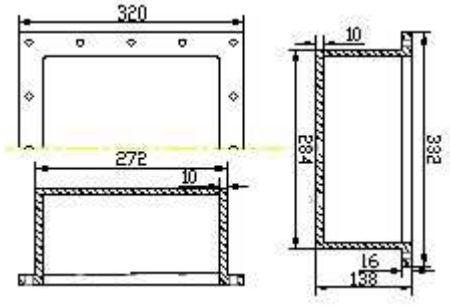

Fig1 The simplified graphic of the wall

Because the explosion-proof enclosure actual structure is complex,it is necessary to simplify off some accessories before calculating,and keep the basic shape and thickness of each panel[3].

The intensity and stiffness analysis of the shell

The theoretical calculation of the intensity and stiffness. The theoretical calculation of the structural strength and stiffness is divided into the elasticity and plasticity theory.The variables in the mechanics are mainly displacement, strain and stress [3].Based on elastic-plastic mechanics,when a material is subjected to a tensile or compressive load of sufficient magnitude, it will deform at first elastically and then plastically.

Based on the assumption of the small deflection of thin plates and the elastic-plastic mechanics theory[4]:

1）The large deflection of a four-sides-fixed rectangle plate:

$$w = 0.00126\frac{p_0 a^4}{D} . \tag{2.1}$$

a is the length of the short edge ; p_0 is the uniformly distributed load;D is the plate's bending strength.

$$D = \frac{Eh^3}{12(1-\mu^2)} . \tag{2.1}$$

E is the elastic modulus;h is the thickness ; μ is the Poisson ratio .

Maximum stress value occurs at the midpoint of the plate's fixed long side edge.When μ is 0.3,Maximal bending moment could be:

$$M_{center} = -0.0513 p_0 a^2 . \tag{2.3}$$

2）The large deflection of a simply supported rectangle plate：

$$w = 0.00406\frac{p_0 a^4}{D} . \tag{2.4}$$

Maximal bending moment occurs at the midpoint of the plate：

$$M_{\max} = \frac{9(1+\mu)}{256} p_0 a^2 \approx 0.0479 p_0 a^2 . \tag{2.5}$$

According to the relation between Stress and bending moment， the maximum stress was obtained：

$$(\sigma_x)_{z=\frac{h}{2}} = -(\sigma_x)_{z=\frac{h}{2}} = \frac{6M_x}{h^2} . \tag{2.6}$$

M_x is the bending moment around the Y-axis.

The concrete calculation result of the model. p_0 is based on the design requirement.the material is Carbon steel Q235-A， E is 2.06 GPa , μ is 0.3.Regarding the bottom and side plate as a simply supported rectangle plate;The cover plate is regarded as the four-sides-fixed rectangle plate .

Table 1 Shell's displacement and stress results under small deflection theory

The panel	Panel size mm	Thickness h/mm	Short edge a/mm	Maximum deflection w/mm	Maximum stress δs /MPa
Bottom plate	284×272×10	10	272	1.18	212.63
The left panel	272×112×10	10	112	0.04	36.05
The right panel	284×112×10	10	112	0.04	36.05
The cover plate	332×320×22	22	320	0.06	65.12

Table 1 is an Excel spreadsheet.We can easily get the initial thickness of the wall plate by Changing the parameter h or a.

The Linear elastic static analysis of ANSYS. Use spatial four nodes elastic shell element SHELL63 to Simulate the elastic plate[5].The analysis results are as follows.

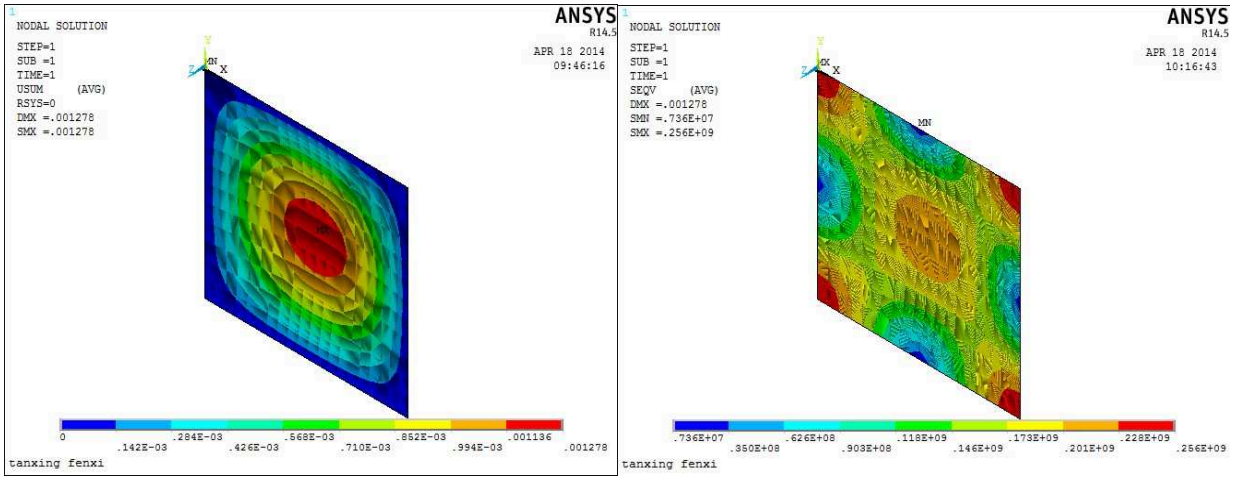

Fig2-1 The bottom board displacement in Z-axes,Fig2-2 The bottom board Mises stress nephogram
Analysis results are consistent with theoretical calculation results.

The plastic analysis and calculation of the wall. The plate's stress should be greater than the yield strength of the material,but smaller than Ultimate strength.Plastic deformation occurred.Therefore, it is needed to carried on preliminary structure optimization.

Table 2 The size and the stress value of the panel after preliminary improvement

The panel	Panel size mm	Thickness h/mm	Short edge a/mm	Maximum stress δs /M Pa
Bottom plate	284×272×9	9	272	393.76
The left panel	272×112×3.7	3.7	112	395.01
The right panel	284×112×3.7	3.7	112	395.01

Material work in the plastic zone at this time.Due to the theoretical calculation value can not reflect the real deformation and stress value， need to carry on elastic-plastic nonlinear analysis by using the ANSYS software.

Nonlinear finite element analysis. Use spatial four nodes Small plastic strain shell element SHELL143 to Simulate the plastic plate[5].The analysis results are as follows.

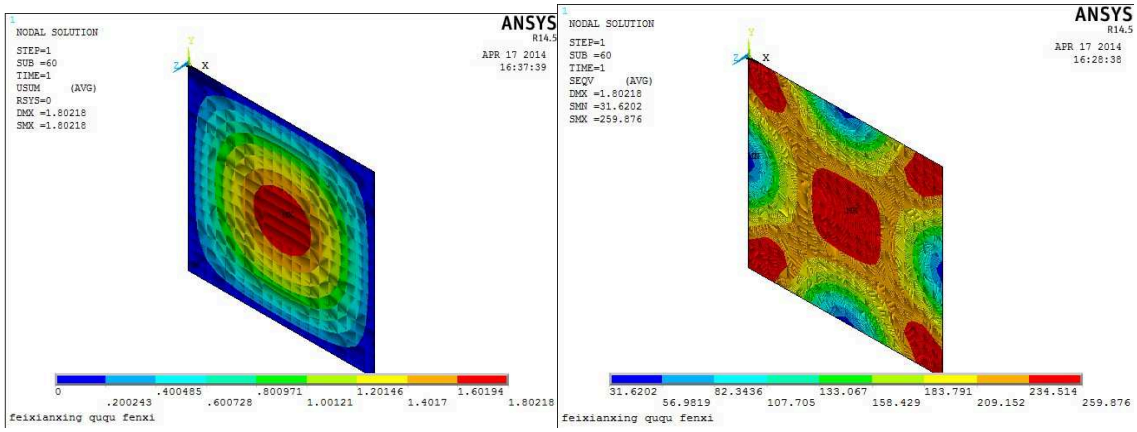

Fig2-1 The bottom board displacement in Z-axes,Fig2-2 The bottom board Mises stress nephogram
Analysis results show that the panel has enough strength,Its biggest deformation smaller than the plate's allowed permanent plastic deformation value.

$$w_{\max} = 1.6mm \le 2\% \times 284mm = 5.68mm \quad . \tag{2.7}$$

The design of the Mine explosion-proof enclosure is reasonable and reliable.

Stiffness analysis of the flange. Explosion pressure produces by the flammable gases's explosion inside of the shells Operates on the flame-proof joint surface ,which forms between the Cover plate and the box flange[2] .The flange must have enough stiffness and cannot occur large elastic deformation or plastic deformation,according to the criteria（GB_3836[1].2-2010）.Through analysis the boundary conditions of the box flange:the shorter edges is Simply supported;a long side is fixed;the other long edge is free .The general calculation formula of maximum deflection:

$$w_{\max} = \alpha \frac{p_0 L^4}{Eh^3} . \tag{3.1}$$

L is the bolt spacing; α is a given deflection coefficient.

The stiffness conditional is the sum of the maximum deflection less than the allowed deflection[2].

$$\sum w\max = w\max + w\max \le (W/2 - A)\psi / K = [f] . \tag{3.2}$$

W is the maximum clearance of flame-proof joint surface;A is the flatness tolerance; ψ is Weld coefficient;K is the safety factor and is set to 1.5.In conclusion ,the flange's theory Thickness can be calculated

$$T_a = a\{\alpha P_0 K / [E(0.5W - A)\psi]\}^{1/3} . \tag{3.3}$$

Explosion-proof surface will suffer certain mechanical damage during being used,such as scratches , pits,etc.Therefore, the designer of Mine Explosion-resistant Enclosure should not only consider the Wall thickness's additional amount of C but also consider retaining some machining allowance.Actual thickness of the flange is as follows

$$T_a = a\{\alpha P_0 K / [E(0.5W - A)\psi]^{1/3} + B + C . \tag{3.4}$$

B is the repair allowance of the flange,Plane flange generally take 15% of the flange thickness and is not less than 1.

$$C = C_1 + C_2 . \tag{3.5}$$

Table 3 Deflection coefficient α

Inspection requirements	Welding by both sides	The single side welding's Weld full length	
		Have backing plates	No backing plates
100%	1.00	0.90	0.75
Local inspection	0.90	0.80	0.70
No inspection	0.70	0.65	0.60

Research for guide groove configuration of rotary valve

Suying Xu

Eaestern Liaoning University,Dandong, Liaoning118003, P.R.China

Xusuying0002@163.com

Keywords: Rotary valve, Spool shaft, Guide groove, Coordinate gap, Leaks

Abstract. Rotary valve is a device to achieve fast commutation hydraulic transmission . Rotary valve is driven by a hydraulic motor drive and can achieve rapid conversion of the hydraulic circuit . Rotary valve spool by a rotating shaft , housing , shafts and bearings and other components. Guide grooves machined on the spool shaft is evenly distributed for hydraulic cylinder into the oil and return oil conversion. The coordinate gap between the spool shaft and valve chamber bore Because will affect the leakage in the leak. How to improve the guide groove structure? We can put the guide groove by high and low partition instead of overlapping arrangement. Reducing leakage within the valve chamber and Meet with the requirements of the spool shaft and valve chamber bore.

Introduction

The method to change the oil hydraulic system is to change the hydraulic oil flow path . The commutation circuit is generally intermittent and slow commutation. To achieve the required hydraulic circuit hydraulic vibration fast commutation, to meet the requirements of the desired frequency . The hydraulic circuit hydraulic vibration requires fast commutation, to meet the required frequency , we can use the rotary valve, rotary valve to meet the low-frequency hydraulic vibrator commutation request.

According to the design requirements of medium pressure hydraulic system. Design pressure of the rotary valve is 16Mpa. The shaft diameter of the rotary valve is 120mm. It can calculate the axial force effected on the rotary valve shaft is 166KN. The diameter of rotary valve shaft with this structure is not too large when the pressure of the hydraulic system is high. With the number of large diameter rotary valve tank can be set on the multi. Under conditions of constant speed rotary valve , the more frequency alternating the oil states , the frequency is high.

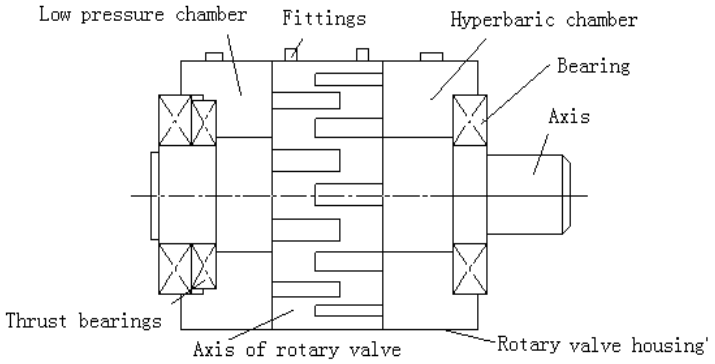

Fig 1 Schematic diagram of the rotary valve

Text Structure and parameters of the rotary valve

Fig 1 is a schematic structural view of the valve rotation .The rotary valve consists of spool shaft, enclosed housing body , bearings, sealing elements and Oil line connectors. Commutation by a plurality of guide groove in the circumferential direction of the rotary valve shaft[1]. The into the oil chamber of the rotary valve is connected with the front chamber of the piston. The front chamber of the piston is always connected with pressure oil. Into the oil circuit and oil return circuit are alternately connected by the with tank of the rotary valve shaft in the after chamber of the piston.

The selection of the coordinate gap of the rotary valve shaft and valve bore

The coordinate gap of the shaft and hole is decidede by two mainly factors. The first gap is that the temperature rise caused expansion by the rotary valve shaft. The second is the leakage what leak from the high pressure oil chamber to the low pressure oil chamber. These two factors determine the size of the clearance value[2].The volume expansion of the rotary valve diameter shaft caused by the temperature changed is :

$$\Delta d = \beta \Delta T d \tag{1}$$

Formula: β- thermal expansion coefficient , ΔT- oil relative to the temperature rise in degrees ℃, d- diameter of the rotary valve.

Chamber provided with a temperature difference between the temperature of the oil is 50 ℃. Rotary valve shaft diameter is 120mm. Diameter incremental of rotary valve shaft is 0.072mm. So control the range . Reduce the oil temperature can reduce the impact of oil changes with the gap .

Fig 2 shows the leakage when the rotary valve is working. Oil leak from the high pressure oil chamber to the low pressure oil chamber. The oil is flowing along the axial direction of the rotary valve and with the direction perpendicular to the tank. According to the structure of the rotary valve ,we can ignore the what is flowing along the axial direction of the rotary valve when we calculating the amount of leakage.It is considered that all the leakage is flowed from the high pressure chamber in the vertical direction of the low pressure sump tank . The leakage is:

$$Q = \frac{b\delta^3 \Delta p}{12\mu\ell} \pm \frac{vb\delta}{2} \tag{2}$$

Formula, The first is the amount of leakage caused by Pressure difference ΔP what is the difference from the high-pressure chamber and the pressure difference . The second is the amount of leakage caused by rotation of the rotary valve. Due to the rotation direction of the rotary valve is fixed, the movement of the rotary valve and side of the oil leak direction the same, the opposite on the other side,so the leakage caused by the rotation of the rotary valve can be cancel each other out. Leakage formula can be changed to :

$$Q = \frac{b\delta^3 \Delta p}{12\mu\ell} \tag{3}$$

Formula;b—Leak channel width m，ℓ—Leakage path length m，δ—Unidirectional gap of rotary valve shaft and valve borem，Δp—Pressure difference between the high and low pressure oil chamber of the rotary valve Pa，μ—Dynamic viscosity of the liquid Pa.s.

Given: b=9.6×10^{-1}m, δ=5×10^{-5}m, $\ell = 7.875\times10^{-3}$ m.

The 20th Oil, $\mu = 1.8\times10^{-2}\ Pa\cdot s$;The 30th Oil, $\mu = 2.7\times10^{-2}\ Pa\cdot s$. Two differential pressure valve chamber is 3Mpa.

Calculation of the rotary valve leakage are $2.126\times10^{-4}\ m^3/s$ and $1.416\times10^{-4}\ m^3/s$ The leakage is so large. By the formula (3), we can see that the amount of leakage is directly proportional to the width of leak channel, δ to the third power and the pressure difference between the two oil chambers, the amount of leakage is the amount of leakage is inversely proportional to the dynamic viscosity of the liquid and the length of the leakage path. We can effectively reduce the amount of leakage by reducing the gap.

The design of the tank matched rotary valve

The diameter of the rotary valve used in the test is 120mm.There are 24 tanks matdhed rotary valve uniformly arranged on the circumference of the shaft. The axial length of the rotary valve is 70mm, the room width of tank is equal to the groove width. The deepth of the groove is 18mm ,the length is 55mm. According to [1], the propagation speed of the hydraulic shock oil is 890-1270m / s.

Turn-on time with a tank is : $t = \frac{1}{n \times n_1}$ (4)

Formula： n —Speed of the rotary valve shaft， r/s; n_1—the number of one-way tank。When the motor speed 1800r/min, t = 1/360s.During this time interval, the opening of the tank with the zero - fully open - closed .When used full opening tank time is 1/720s. At this point the flow is maximum , the flow cross-section is $18 \times 7.85\,mm^2$.

The impact of hydraulic shock velocity： $\Delta P = \rho cv$ (5)

Formula： ρ —liquid densitometer Kg/m^3 v —The original flow rate in the tubing， m/s; c —Propagation velocity of shockwave， m/s.

Since the switching of the tank is in the commutation off state. Hydraulic shock produced additional impact pressure ΔP on the actuators. Hydraulic shocks can be reduced by increasing the width of the tank.That is the between width and groove width is not equal. The width is greater than the width between slots, so the switching with the oil is carried out continuously.

In Fig 1 we can see that the rotary valve leakage volume staggered overlapping tank matched rotary valve structure. The width of the leakage path is long , the length of the short leakage path is short . Therefore, the structural design of the rotary valve should give more consideration to the impact of leakage. Reasonable choice leakage channel width and length can effectively reduce the leakage of the rotary valve . In the condition of larger of difference pressure of two oil chambes , rotary valve leakage should be less than 20% of the main drive pump output volume .

Improved structural design of rotary valve

To further reduce the gap to reduce the leakage is already impossible. By the formula (2) we can seen that the amount of leakage is directly proportional to the width of leak channel,and inversely proortinal to the length of the leakage path. If b is reduced or ℓ is increased from the structure can be further reduced leakage[4].

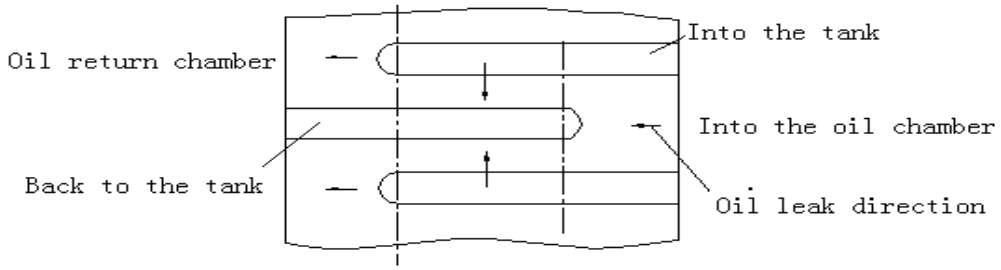

Fig 2 . Sump configuration diagram overlap

Leakage along the direction perpendicular to the sump. If the tank is configured in the form of non-overlapping. Tank configurations shown in Fig 3.

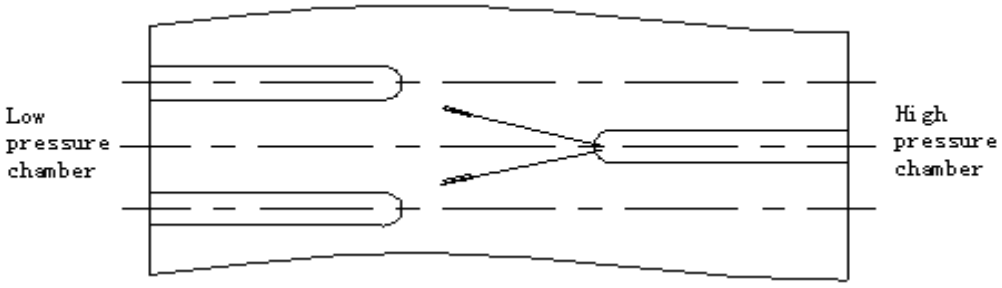

Fig 3 . Schematic diagram of non-overlapping configuration tank

In this configuration , the direction of the main flow of the oil leake is the axial flow [5].In this case the width of the drain passage b = 2πd .The length of the leakage path $\ell = \frac{1}{2}(\ell_{\min} + \ell_{\max})$ leakage flow throughthe annular gap .

$$\Delta Q = \frac{\pi d \delta^3 \Delta p}{12 \mu \ell}(1+1.5\varepsilon^2) \tag{6}$$

Formula： ε —Relative gap eccentricity.

Let's the structure size of the rotary valve : $d = 1.2\times10^{-1} m$ $\ell = 5.75\times10^{-2} m$, $\delta = 5\times10^{-5} m$. Pressure ： $\Delta p = 8MPa$ .Oil viscosity，t=50℃, $P = 8MPa$

The 20th Oil, $\mu = 1.5\times10^{-2} Pa\cdot s$ and the 30th Oil, $\mu = 2.7\times10^{-2} Pa\cdot s$.

When $\varepsilon = 0.5$ Leakage calculations are $4.5\times10^{-5} m^3/s$ and $2.70\times10^{-5} m^3/s$.

Such leakage relative to the pump output flow is allowed.If the allowable values [q] of the leakage was given, the gap value flowde through the annular gap can be calculated.

$$\delta = [\frac{12[q]\mu\ell}{\pi d \Delta p(1+1.5\varepsilon^2)}]^{\frac{1}{3}} \tag{7}$$

Let the allowable values $3.33\times10^{-5} m^3/s$ corresponds to the 20th Oil, $\delta = 5.6\times10^{-2} mm$ .30th Oil, $\delta = 6.4\times10^{-2} mm$. It can be seen that the amount of δ can put a gap wider than the tank get some of the overlapping structure.

Conclusion

The rotary valve consists of Spool shaft, transmission shaft, enclosed housing body, bearing, sealing elements and oil line connector. Rotary valve is a device to achieve fast commutation hydraulic transmission

The leakage of rotary valve is affected by the length of the drain channel and the gap between the spool shaft and the housing bore.The shorter distance is from the guide groove between the spool shaft to the drain oil passage of the r overlaped otary valve, the amount of leakage is greater. So the coordinate gap of the spool shaft and the hole must be smaller. Due to the increase of temperature , the gap is according to the temperature requirements, the guide groove of the rotary valve spool shaft must be overlapping set . The result is to reduce the pressure of the high pressure region.

Changing the arrangement of the axis of rotation of the guide groove of the spool, Change the original overlapping arrangement of high and low partition layout, meet with the requirements of the spool shaft and valve chamber bore

Keywords: radar stealth technology, shape technique, radar-scattering characteristic, radar cross section (RCS), tank turret

Abstract. Radar-scattering characteristic which is an important aspect in stealth technology plays a key role in radar detection. Based on shape technique, this work studied the influence of geometric parameter on radar-scattering characteristic for a tank turret by establishing a scaled model as well as calculating the radar cross section (RCS) of this model. The results show that the tank turret can obtain better radar-scattering characteristic with much lower RCS by optimizing its shape and the dihedral angles between the tank turret and the tank body.

Introduction

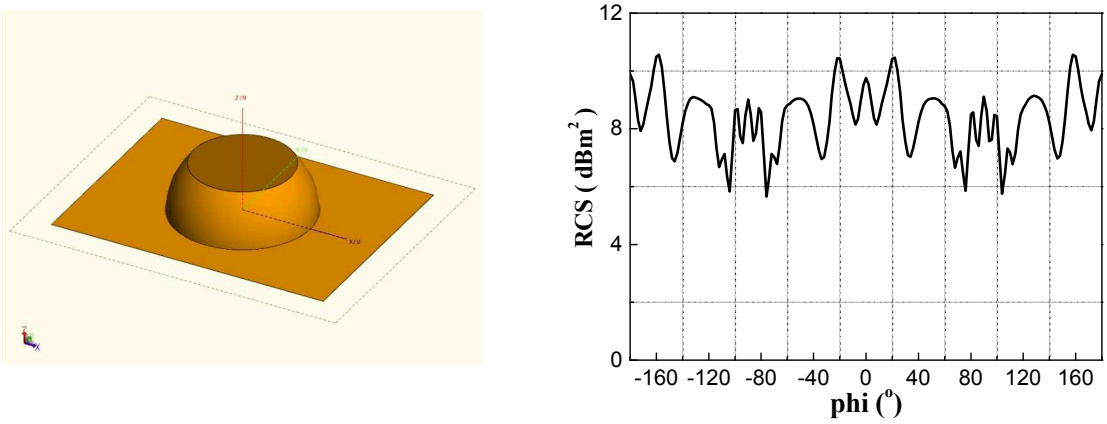
Radar detects targets based on the difference of radar-scattering characteristic between the targets and the background. Therefore, radar-scattering characteristic plays an important role in radar detection and has also attracted much attention in stealth technology. Radar stealth technology is mainly used for reducing the probability of the targets detected by enemy radars, and is realized by reducing RCS of the targets through suppressing, absorbing and/or deviating radar echo signal [1]. Radar stealth technology has been intensively studied and widely used in military powers all around the world to degrade radar performance and improve battlefield survivability of weapon equipment.

Based on the interactive mechanism between radar wave and substance, main factors determining the radar-scattering characteristic of the target include surface materials of the target, target shape and incident direction of radar wave, etc. So far, absorbing materials and shape technique are two main ways to achieve radar stealth. Compared with the former, the shape technique suppresses echo signal and reduce RCS by changing target shape, thus resulting in the low possibility of the target being detected. This work studied the influence of shape technique on radar-scattering characteristic by establishing a scaled model as well as calculating the RCS of this model.

Radar-scattering characteristic of a scaled model for a tank turret

Tank faces serious threats from various high-efficiency anti-tank weapons in a battlefield. Among them, the threats related to radar mainly come from surveillance tracking radar and fire control radar, etc. The threat directions of radar against tanks are at the front and lateral sides with pitching angle ranging between 0°and 15° [2]. Among various components constituting a tank, the tank turret is especially easily to be detected by radar, because the RCS of a tank turret typically reaches up to tens of square meters at the front-side direction, and even increase with increasing pitching angle, which is harmful for tank survival in the battlefield.

Traditional tank turrets have a curved surface (e.g., cylindrical surface and cutting spherical surface), which leads to nearly omni-direction reflection of radar wave. To gain more insight into the radar-scattering characteristic for a traditional tank turret, we setup a scaled model based on a traditional tank turret with cutting spherical surface (shown in Fig. 1(a)) and calculate the corresponding RCS by using the software FEKO (shown in Fig. 1(b)).



(a) (b)

Fig. 1 Traditional tank turret with curved surface. (a) The scaled model. (b) The RCS value.

From Fig. 1(b), the radar wave reflection for the traditional tank turret in Fig. 1(a) displays a uniform distribution in different azimuth angles. Furthermore, the calculated RCS can reach up to about 10 dB, which suggests that the scattering is intense, and therefore, the tank is easily detected by radar. Further efforts should be made to suppress the intense scattering.

Basic shape design for tank turret to improve the radar-scattering characteristic

To improve the radar-scattering characteristic, the French AMX-30B3 tank turret proposed an innovative polyhedron design [3]. Following this innovation, then most tank turrets have adopted flat surface by assembling pieces of large-area planes together, which is known as shape technique. It is noted that for the flat surface, although the side lobe intensity decays rapidly, the main lobe intensity is usually strong [4]. Therefore, it is believed that the flat surface can further improve the radar-scattering characteristic with remarkably low RCS if the main lobe of backscatter pattern is intentionally derived from the threat direction [5].

Therefore, the work need to do here is to appropriately select the inclined angle of flat surface. Fig. 2 shows the cross-sectional diagram as well as the key geometric parameters of the tank turret with flat surface, where γ represents the inclined angle of lateral surface for the tank turret, θ_c represents the range of radar threat angle, and $\Delta\theta$ is the angle between the surface normal direction n and the radar wave incident direction k.

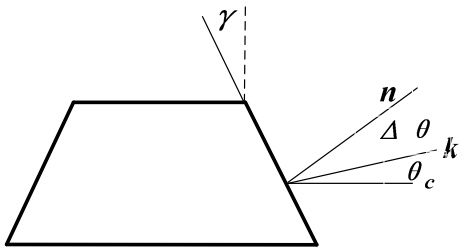


Fig. 2 RCS reduction principle of tank turret with flat surface.

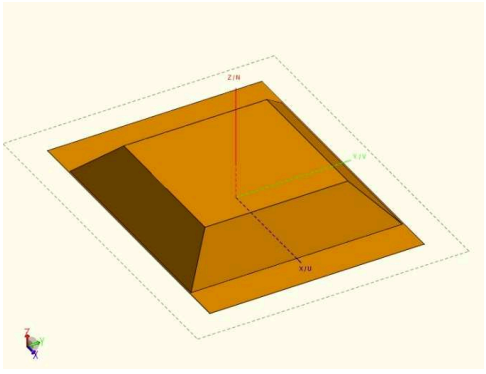
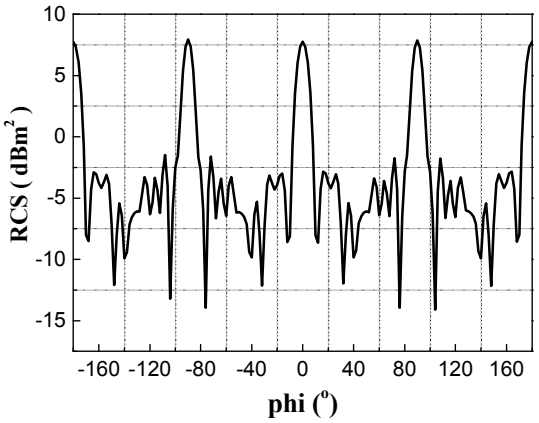
From the geometrical relationship, γ can be expressed by

$$\gamma = \Delta\theta + \theta_c. \quad (1)$$

Note that θ_c as a variable is typically ranging between 0° and 15°. It is important to determine an optimal γ to make sure that not only the main lobe of backscatter pattern deviates from the threat direction, but also the RCS always keeps a low value as θ_c changes. Based on the above principle, a

series of simulation were performed by adjusting γ and then evaluating the RCS as θ_c changes under a given γ. Finally, we got the optimal model of the tank turret with flat surface shown in Fig. 3(a) as well as its calculated RCS shown in Fig. 3(b).





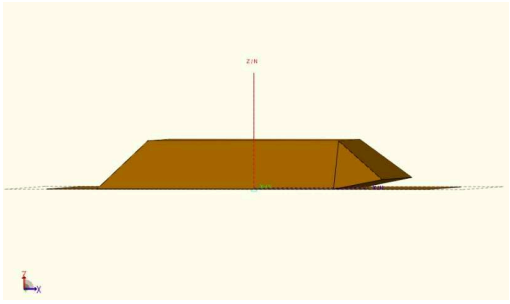
(a) (b)

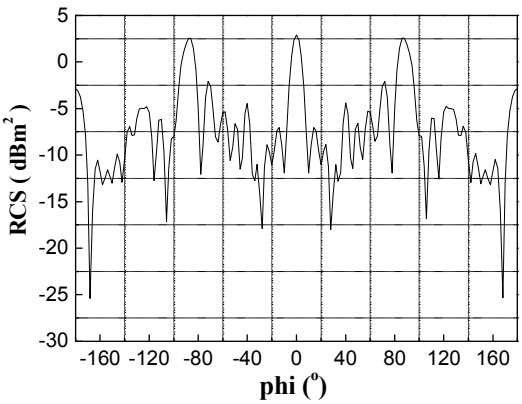
Fig. 3 Optimal tank turret with flat surface using shape technique.
(a) The scaled model. (b) The RCS value.

As shown in Fig. 3(b), the optimal RCS by adjusting the geometrical parameters based on the shape technique is mainly below 0 dBm^2 and the minimum value is even as low as -14dBm^2, which is much smaller than the value for the traditional tank turret with curved surface in Fig. 1(b). Therefore, by optimizing the geometrical parameters, the shape technique is an effective way to suppress the RCS, and thus significantly reduces the probability of the tank being detected.

Further improvement of radar-scattering characteristic

In Fig. 3(a), the large-area planes used for constructing the tank turret form dihedral angles relative to the tank body. These parasitic dihedral angles are obtuse angles and usually lead to large back scattering in a wide range. In order to remove the adverse effect induced by these obtuse angles, we also propose a novel shape as shown in Fig. 4(a), where the formed dihedral angels turn to acute angles by optimizing the turret shape. The RCS based on this novel shape is also calculated and present in Fig. 4(b). Compare with the RCS for the turret with obtuse dihedral angles in Fig. 3(b), it can be seen that by using acute dihedral angles instead of obtuse dihedral angles, the RCS of the turret is obviously reduced, suggesting that the back scattering are significantly suppressed.





(a) (b)

Fig. 4 Tank turret model with acute dihedral angles between the tank turret and tank body.
(a) The scaled model. (b) The RCS value.

Summary

This work studied the influence of shape technique on radar-scattering characteristic of a tank turret by establishing a scaled model as well as calculating the RCS of this model. The results demonstrate that tank turret can obtain improved radar-scattering characteristic with low RCS by optimizing the geometric parameters of the turret itself and the dihedral angles between the turret and the tank body.

Feasibility Investigation for Visible-Laser Compatible Camouflage Thin Film

Zhu Liyan[a], Xu Weidong[b], Wan An, Zeng Zhaoyang and Ma Yao

PLA University of Science and Technology, Nanjing, 210007, China

[a]zhuliyan0522@163.coml, [b] xweibing1968@aliyun.com

Keywords: thin film. visible. laser. camouflage.

Abstract. Based on multi-layer film interference theory and optimization calculation, a film structure that can satisfy both visible and 1064nm laser camouflage requirements were put forward. The light transmission property of the structure was analyzed systematically and the thickness and refractivity of different layers were obtained.

Introduction

Wide application of modern electrooptical technology in surveillance and guidance results in expose of both sides in war, which means fatal threaten for military targets. As effective method to against surveillance and guidance, camouflage technology is off great importance. Technically the materials used in camouflage should be able to decrease the expose signs of target at all surveillance frequency. However, the camouflage materials presently available can't provide ideal compatibility, thus improvement in property is needed urgently. In optical band, the camouflage material should simulate the optical property of plant, which means high reflectivity in the 680~1200 nm band. As for laser camouflage, high reflectivity at 1064 nm wave length is unacceptable. Thus, new materials are necessary for visible-laser camouflage[1].

After many years of development, optical thin film has become very important part of optical technology. Complete analysis theory and design methods have been verified. Proper design for multi-layer film can enhance or weaken light transmission, thus structure design of film has potentiality in camouflage. The structure investigated in this paper was designed in such a way that it could remain high reflectivity while the reflectivity at 1064 nm was minimized. This property makes it possible to take infrared and laser camouflage into account simultaneously.

Basic theory for thin film

When a thin film is illuminated by a light beam, reflection and transmission rate is the result of multiple-beam interference (as shown in Fig. 1).

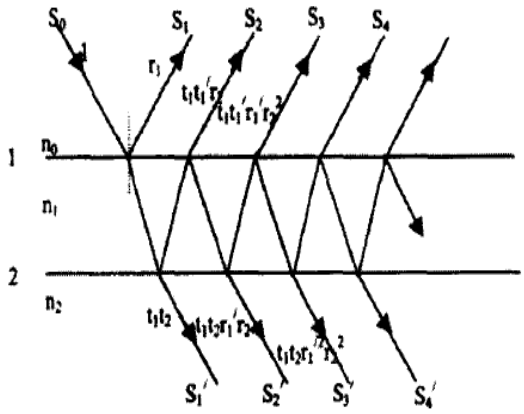

Fig. 1 Multiple-beam interference in thin film

For the purpose of convenience in light intensity calculation, the method of complex amplitude was used. In the following, r is the reflectance for light entering form medium with refractivity n_1 to medium with refractivity n_2, t is the transmittance. r′ is the reflectance for light entering form medium n_2 to medium n_1, t′ is the corresponding transmittance. If the refraction between medium n_1 and medium n_2 is neglected, then we have

$$r = -r' \tag{1}$$

$$r_2 + t_1 t' = 1 \tag{2}$$

If the absorption within the film is neglected and the amplitude of the incident light is supposed to be 1, then the amplitude of different beams in Fig. 1 is

$$\begin{cases} s_1 = r_1 \\ s_2 = t_1 t' r_2 \\ s_3 = t_1 t' r_1 r_2^{\,2} \\ \cdots\cdots\cdots\cdots \end{cases} \tag{3}$$

The subscription 1 and 2 in the above represent the upper surface and the lower surface, respectively. As for amplitude of the transmitted beams, it can be written as

$$\begin{cases} s_1' = t_1 t_2 \\ s_2' = t_1 t_2 r_1' r_2 \\ s_3' = t_1 t_2 \left(r_1' r_2\right)^2 \\ \cdots\cdots\cdots\cdots \end{cases} \tag{4}$$

The phase difference between adjacent beams is decided by

$$\delta = 2 n_1 d \cos\theta$$

where d is the film thickness, and θ is the incident angle.

Thus, the amplitude of the reflected beam from upper surface is

$$r = \left\{ r_1 + t_1 t_1' r_2 e^{-i2\delta} \left[1 + r_1' r_2 e^{-i2\delta} + \left(r_1' r_2\right)^2 e^{-i4\delta} + \ldots \right] \right\} \tag{5}$$

According to summation law of geometric sequence, the above equation can be reduced to

$$r = \left(r_1 + r_2 e^{-i2\delta}\right) \Big/ \left(1 + r_1 r_2 e^{-i2\delta}\right) \tag{6}$$

The phase change of the reflected beam is

$$\tan\varphi = \left[-r_2 \left(1 - r_1^{\,2}\right) \sin 2\delta \right] \Big/ \left[r_1 \left(1 + r_2^{\,2}\right) + r_2 \left(1 + r_1^{\,2}\right) \cos 2\delta \right] \tag{7}$$

Finally, the total reflectivity of the film is[1,4].

$$R = r \cdot r^* = \left(r_1^{\,2} + r_2^{\,2} + 2 r_1 r_2 \cos 2\delta\right) \Big/ \left(1 + r_1^{\,2} r_2^{\,2} + 2 r_1 r_2 \cos 2\delta\right) \tag{8}$$

Structure design for visible-laser compatible camouflage design

The system of visible thin film can always be represented by an effective interface, of which the reflection and transmission are determined by the conductance of the incident medium and the assemble conductance of the effective interface. The effect of every layer can be explained in term of its influence on the effective interface conductance. For multi-layer visible thin film, the feature matrix of the film is the product of the feature matrix of different layers,

$$\begin{bmatrix} B \\ C \end{bmatrix} = \prod_{j=1}^{k} \begin{bmatrix} \cos\delta_j & \frac{1}{\eta_j}\sin\delta_j \\ i\eta_j \sin\delta_i & \cos\delta_j \end{bmatrix} \begin{bmatrix} 1 \\ \eta_{k+1} \end{bmatrix} \tag{9}$$

The assemble conductance of the multi-layer film is Y=C/B, thus

$$B = \left(\frac{\eta_0 B - C}{\eta_0 B + C}\right)\left(\frac{\eta_0 B - C}{\eta_0 B + C}\right)^* \tag{10}$$

$$C = \frac{4\eta_0\eta_{k+1}}{(\eta_0 B + C)(\eta_0 B + C)^*} \tag{11}$$

$$\phi = arctg\left\{\frac{i\eta_0\left(CB^* - BC^*\right)}{\eta_0^{\,2}\left(BB^* - CC^*\right)}\right\} \tag{12}$$

The above equations consist of the foundation for property calculation for thin films[2-4].

A kind of A/0.025M10(HL)/S structure was analyzed in this paper, of which the reflection and transmission were calculated according to the equations mentioned above. In this structure, A represents air, S is the basement. M is the mental layer with refractivity 4.53 [5,6]. H is the TiO_2 layer with refractivity 2.15, whereas L is the MgF_2 layer with refractivity 1.38. The calculated results are shown in Fig. 2 to Fig. 4. The central wavelength is set to be 1064 nm. Obviously, the reflection rate within the 380~780nm band is about 70%, whereas the reflection rate at 1064 nm is only 25%. This kind of spectral reflectivity is just wanted by visible-layer compatible camouflage.

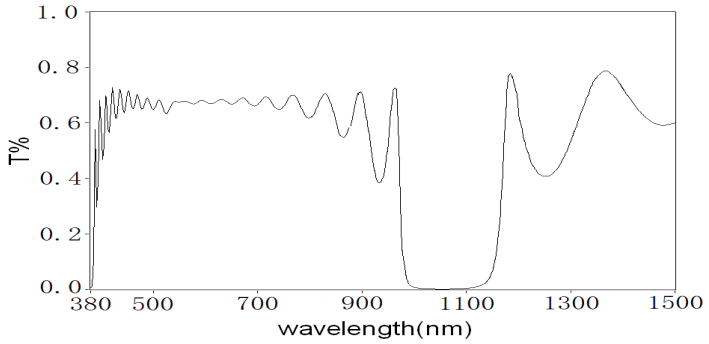

Fig. 2 The calculated transmission curve of the multi-layer system.

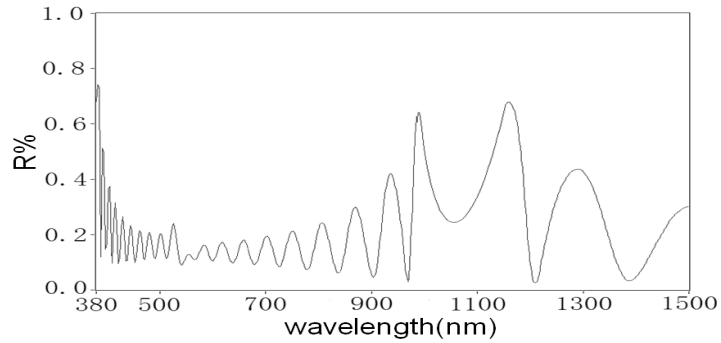

Fig. 3 The calculated reflection curve of the multi-layer system.

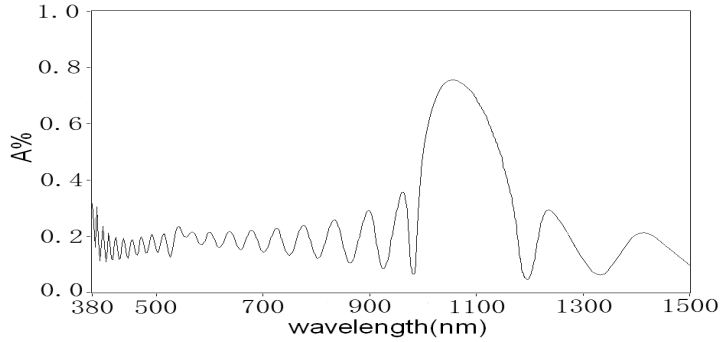

Fig. 4 The calculated absorption curve of the multi-layer system.

Conclusion

Spectral reflectivity of multi-layer system was calculated according to thin film theory. The results indicate that proper structure design can effectively reduce the reflection rate at 1064 nm wavelength, whereas the reflection within the visible band remains high. This film structure make it possible for visible-layer compatible camouflage.

PWM Control for Actively Clamped Resonant DC-Link Inverter on Soft-Switching

SHE Yan

Shunde Polytechnic, Foshan 528300, China

Shelley186@sohu.com

Keywords: soft-switching; active inverter; SVPWM; double CPU

Abstract. Due to the active inverter in industrial application, if use hard switching mode, not only may have the switch losses, but also may produce electromagnetic interference and harmonic, these power quality is affected. This paper presents the design of a soft-switching active inverter, that active clamped resonant DC-link inverter topology was used on the main circuit, the voltage space vector pulse width modulation (SVPWM) control mode was used on control circuit, using TMS320LF2407DSP programming, while the AT89C51 was responsible for liquid crystal display task, data exchanged and coordinated between double CPU. The experimental results show that, the device switching-losses can effectively reduce, the switching frequency can improve, input power quality can improve.

Introduction

Because the traditional inverter switching device exist high voltage and current stress, high du/dt and di/dt due to switching on and off form electromagnetic interference, and the influence of harmonic will reduce the power factor of the power grid, cause trouble to other electrical equipment in power grid. Generally the soft-switching PWM converter technique was used as a defensive measure[1]. This paper puts forward the effective design scheme for an active clamped resonant DC-link inverter topology, verify the feasibility and superiority of this scheme through the experimental study.

Soft Switching Inverter Main Circuit Design

The design adopts soft switching active clamp parallel resonant DC-link inverter main circuit as shown in Figure 1, through the control mode of SVPWM, make the resonant link and inverter main circuit matching, When the switching, first the DC bus voltage drop to zero through the resonance, then the switching device of inverter main circuit carry on soft switching, thereby reduce the voltage and current stress of the switching device, voltage stress clamp under the battery voltage Ud. Concrete analysis is as follows [2]:

State 1: Vs=on, Va~Vb=off, during T0 period, the flow of the load current is in Vs circuit, LrCr circuit is at rest.

State 2: Vs=on, Va~Vb=on, at a certain time, conducting Va and Vb , the action belongs to ZCS, inductor Lr current increases linearly from zero, until can maintain the needed energy to complete the process of the resonance, shutdown Vs, When the capacitor Cr voltage is kept Ud constant.

State 3: Vs=off, Va~Vb=on, shutdown Vs, the action belongs to ZVS. Then LrCr begin the resonance,

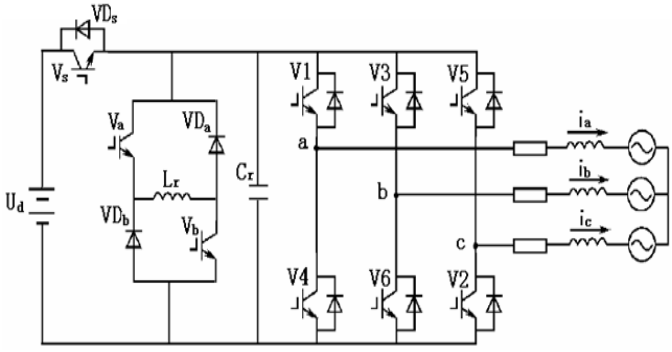

Fig.1 Inverter circuit topology structure

with resonant, capacitor voltage ucr drop to zero, the inductor iLr current increase to the maximum value ip, that provides ZVS conditions for the inverter switch tubes.

State 4: Vs=off, Va~Vb=on, capacitor ucr voltage remains zero, the inductor iLr current form loop circulation to continue along Va~VDa and Vb~VDb. During this mode, inverter switching devices with ZVS switch to the next state.

State 5: Vs=off, Va~Vb=off, After switching inverter, shutdown Va and Vb, the action belongs to ZVS. then the capacitor ucr voltage is slowly rising, the inductor iLr current form loop circulation to continue along VDa, VDb and Cr. due to LrCr resonance, ucr rise to Ud.

State 6: Vs=on, Va~Vb=off, when the capacitor voltage is slightly higher than Ud ,that with ZVS, diode VDs conduct with ZVS, capacitor voltage clamp on Ud, residual energy of Lr inductance feed to the power supply. The inductor iLr current drop to zero from I2, and the diode VDa, VDb, shutdown with ZCS.

So far, the resonant circuit complete a cycle. The waveform is shown in figure 2.

The resonant circuit can not only change the pulse width (DC-bus during non zero voltage), but also can change the pulse position, AC voltage waveform of inverter can control to has convenient, synchronizing with grid[2]. AC voltage waveform generated by the inverter can be real-time controlled to realize the synchronized with the power grid.

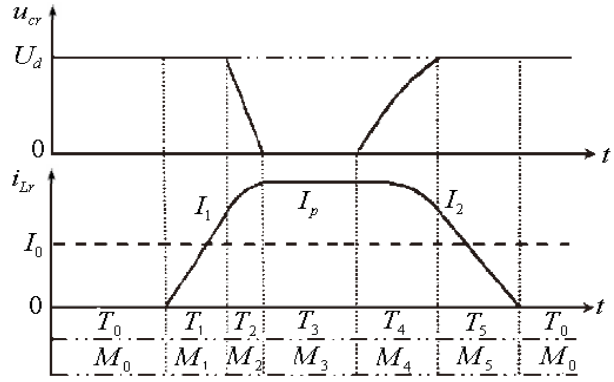

Fig.2 The waveform

The Design of Control Circuit

The design of control circuit plays a very important role in the inverter system, Here using two processors, TMS320LF2407 complete the main function of switch input and output, A/D converter, communication, SVPWM waveform output[3], AT89C51 is used to complete the liquid crystal display function.

The Measurement Circuit of A/D Conversion. The three-phase AC-side voltage and current amplitude, frequency, phase of the main circuit and DC-side voltage and current must accurately sampling in order to control the SVPWM waveform, make inverter generated AC waveform in accordance with the requirements of the grid. Three-phase AC-side select transformer to measure voltage and current, DC-side select Hall element to measure voltage and current, A/D converter provided by the LF2407 chip can complete these tasks, without the need for external A/D circuit. Figure 3 is the design of the AC voltage and current detection circuit, output amplitude < 3.3V with same frequency sine wave.

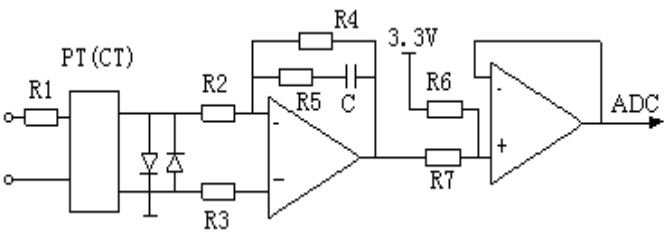

Fig.3 AC side voltage-current detection

The design of Communication Interface Circuit. As the need of the control system with PC communication, thus require communication circuit, TMS320LF2407 itself as a SCI interface, so you can easily achieve communicates with PC. Here the communication have two functions: one is to device parameter settings through the computer to download; two is that the device send the data monitored to a computer for further processing. The system design two kinds of commonly used serial communication interface standard RS232 and RS485 interface circuit, RS232

for local data transmission; RS485 for remote data transmission[4][5]. SCI serial communication circuit diagram is shown in figure 4 below.

SVPWM Output and Drive Isolation Circuit. Using SVPWM control algorithm and the DSP programming, produces 6-channel programmable dead and variable output polarity of the PWM waveform, drive IPM inverter module power device of the main circuit, through a drive circuit and a photoelectric isolation circuit, obtain sine waveform of a variable-voltage and variable-frequency effect, supply electrical power[4][6]. PWM isolation output circuit diagram as shown in Figure 5. The fault input signal can be sent to the main control board after the isolation.

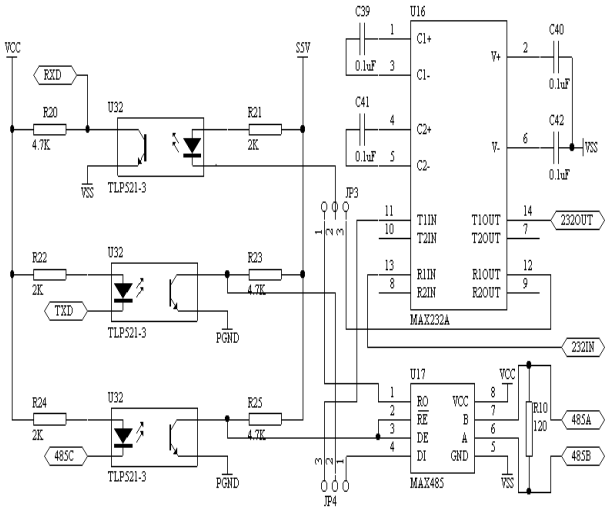

Fig.4 SCI serial communication circuit

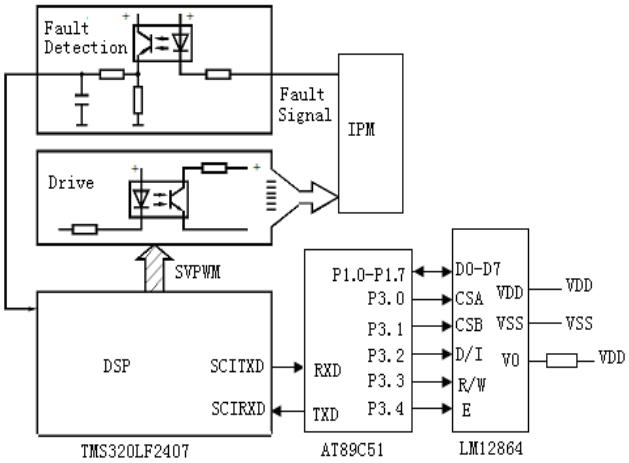

Fig.5 The SVPWM isolation output circuit and display interface circuit

Liquid Crystal Display Interface Circuit

Through send-receive data pins SCITXD, SCIRXD of the SCI module connected with AT89C51 serial input port RXD, TXD, the data will be sent to MCU to display. Because the TMS320F2407 is the device of TTL 3.3V level, and AT89C51 is the 5V device, the two are connected by two pieces of MAX3232 as DSP and MCU Interface, this method not only takes up DSP two I/O port, but also can extend the communication distance using RS232 interface, improve the anti-interference capability, and ealize the function of software[7]. using LM12864 in the liquid crystal display module, it is the LCD module with a built-in 128*64 Chinese characters dot matrix, can display letters, numbers, Chinese fonts and custom blocks, and the interface of MCU is flexible, the structure block diagram is shown in figure 5.

Conclusion

This paper analyzes the working principle of the active clamped resonant DC-link inverter on soft-switching, PWM control scheme for the active clamped resonant DC-link inverter is verified using double CPU, and effective waveform is obtained as shown in Figure 6 and figure 7[8][9]. Through the analysis of the experimental study showed that: 1) the inverter switches running on ZVS or ZCS, can reduce the switching losses and improve the switching frequency, and reduce the EMI; 2) the voltage stress of component is clamped at the DC voltage for device selection and circuit operation; 3) can output high precision waveform under SVPWM control mode , improve power quality, reduce the low order harmonic loss, is conducive to the application of the PWM active clamped resonant DC-link inverter to high performance and high power output.

Design improvement on shipping container spraying production line

Okorie Sunday Onyedikachi[a], SHI Jing[b]

School of Mechanical Engineering and Automation, Liaoning University of Technology, Jinzhou 121001, Liaoning, China
[a]2243554142@qq.com, [b] 464408756@qq.com

Keywords: flip-frame, hydraulic cylinder clamping, chain drive, sprocket, mechanism

Abstract. This paper describes the design of a flip-frame mechanism for shipping container spray painting production line. The idea of the flip-frame mechanism is to reduce, to a large extent, paint wastage during spray painting of the quadrangular exterior surfaces of the shipping container. Clamping of the shipping container on the flip-frame is achieved by hydraulic cylinders. A roller chain and a sprocket is used to drive the flip-frame because of their simplicity, strength, ability to work under harsh condition and require little lubrication.

Introduction

In recent times, automatic spray-painting system for shipping containers has gone through several reform stages. These extensive reforms were borne out of global innovation in shipping-container industries, leading to constructive thinking in order to improve upon the existing state of the shipping container spray-painting production line. In the past, manual painting was applied to shipping containers while some cases involved the use of automatic spray guns operated manually by human labour; the results wasn't appealing enough due to even distribution of paints on the container walls were hardly achieved.

The introduction of automatic spray-painting booth system did not solve all the problems inherent to painting completely. Achieving even distribution of paint on the sprayed surfaces while spraying is still a major challenge. 'Painting requires that the spray gun deposit paint at each point on the target surface such that the variation of the resultant paint deposition is within acceptable limits; we term this the uniform coverage problem' [5].

Roland Bizolier in 1992 did some remarkable work in this area of research which he titled "Automatic painting machine particularly for painting the inside of a hollow body of quadrangular section and large size such as a shipping container" [4]. His work addressed the problem of spray painting the inside of the hollow body of a shipping container but did not address properly the problem of spray painting the external surfaces of the shipping container.

Current Situation

There are many fundamental challenges and issues that are still impeding and restraining reforms in the container production industries of which some would be solved by this research work. In this research, a close look is being given to some shipping container spray painting production lines within and outside China, in order to carry out this design improvement effectively.

From current findings, the following conditions are predominant in most shipping container spraying production line:

Paint wastage. Large amount of paints are being dropped during spray painting of shipping container walls, especially at the left and right sides of its quadrangular external surfaces. This continuous paint droppings constitute large portion of the paint wastage since they drop directly to the floor and recovery is most likely not possible.

Quality of spraying. The beauty of every finished product, no matter its proposed usage, is its appearance. Hence, the appearance of every product tells more about the finishing processes. The quality of sprayed shipping containers need to be improved. Even distribution of paint on the walls

of the shipping container while spray painting is a major challenge hindering the quality of the finished painted product, since manual labour is still required in large extent to operate the automatic spraying guns.

Human labour. Human labour is another major challenge being struggled with in most of these industries. The toxic nature of the paint pose great treat to the health of these workers, hence most workers don't retain their jobs at the spraying section of the production line; this leads to continuous loss of expatriates**.**

Safety on the Production Environment. Safety on the production environment is a major concern that cannot be overemphasized. It is as vital as the melting furnace to a Goldsmith. Inadequate control over (enforcement of) safety constraints, can occur either because hazards and their related constraints were not identified or because the control actions do not adequately enforce the constraints [3]. Also, the changes in work organizations and technologies without proper workers sensitization pose serious problem of workplace accidents. The employees are subjected to the known and unknown risk of occupational injuries and illnesses.

The Flip-frame Mechanism

Today, the concept of flipping (flip) can be found in many designs, ranging from clocks, maker boards, mobile phones, laptop computers, vehicles, etc. In this research work, the flip-frame mechanism is design to accommodate the shipping container in its hollow quadrangular section (see figure 1). A double-strand roller chain of ANSI No.240 is wound round the spherical center surface of the flip-frame. Attached to this double-strand roller chain is a sprocket. The sprocket is driven by an electric motor such that is allows a forward and reverse rotation of the flip-frame at a maximum angle of 180 degree (180°) from the starting point as demonstrated below in figure 2.

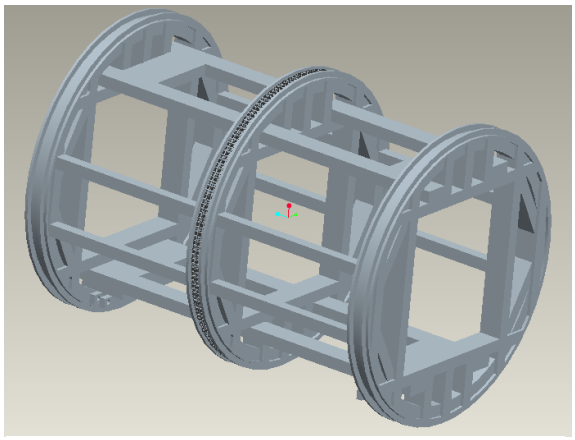

Figure 1: The flip-frame

The 6058mm (length) by 2591mm (height) by 2438mm (width) shipping container size is being used in designing this flip-frame mechanism, though larger shipping container sizes are applicable as far as the flip-frame is designed to accommodate such.

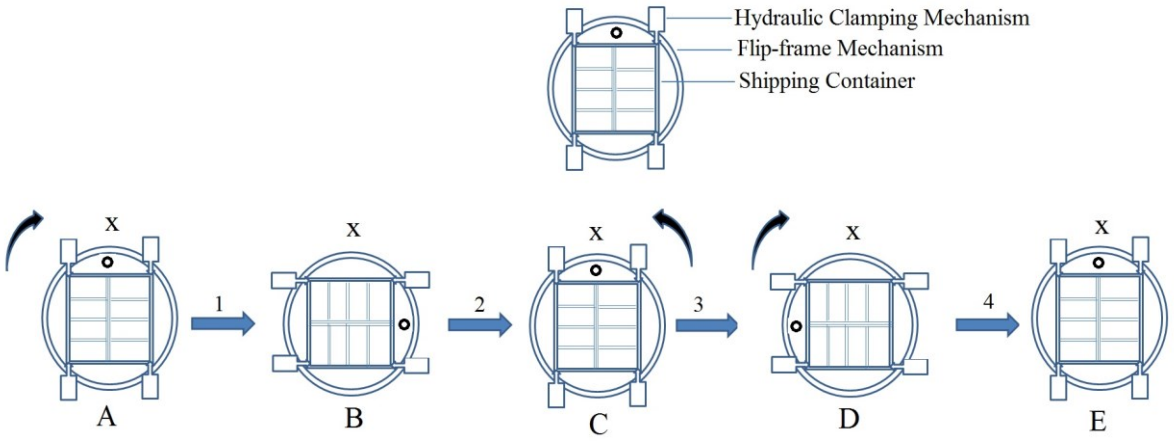

Figure 2: Rotations of the Flip-frame Mechanism

As the shipping container fits into the hollow quadrangular section of the flip-frame mechanism, the positional limit switch attached to the flip-frame switches-off the translational assembly line. Then the hydraulic cylinders attached to the flip-frame clamp the shipping container

on it corner posts. The exterior surfaces of the shipping container is made to be directly under the fixed automatic spraying guns, X, by the flipping of the frame (see figure 2).

After the clamping is done, the automatic spraying guns, X, are activated and spraying of the exterior surface directly under and parallel to the spraying guns, as seen in figure 2(A), is achieved. Following this, the flip-frame rotates at an angle of 90^o from A-B as seen at position "B" in the figure 2, after which the current surface is being sprayed. The same process occurs at point "D" after rotation to an angle of 180^o in the direction of B-C-D is achieved. The flip-frame is rotated at an angle of 90^o in the reverse direction from D-E so that position "E" is attained.

The flip-frame mechanism ensures that the exterior quadrangular surfaces of the shipping container are being sprayed only when they are directly beneath the automatic spraying guns "X". At this position, paint drops to the floor is almost zero since the surfaces are always horizontal and parallel to the spraying guns. Paint wastage occurs mostly when the external quadrangular surfaces of the shipping container are in vertical position parallel to the spraying guns during spray painting

Significance of this Design Improvement

Paint wastage during spray-painting will be drastically reduced. This research work aims at reducing paint wastage during spray painting of shipping containers to about 50%. Since the automatic spraying gun will only spray the exterior quadrangular surfaces of the shipping container when each side of the shipping container surface is rotated by the flip frame mechanism to be directly under and parallel to the automatic spray guns (see figure 2).

The plant production environment will be improved. Since the introduction of the flip-frame mechanism is a new innovation in the shipping container spraying production line, the production environment will definitely improve due to the new automation processes involving the flip-frame mechanism.

Increased safety on the production environment. Since the number of human labour in the spraying production line will be reduced by the implementation of the flip-frame mechanism, it is also expected that accidents in the production line will also be reduced since less human activities will now be require in the spraying production line. Hence, human accident will be reduced and safety increased.

Save labour. More labour force were required to handle and operate the automatic spraying guns while spraying the exterior quadrangular surfaces of the shipping container, but the introduction of the flip-frame mechanism will reduce this labour force since the automatic spraying guns will be fixed at an upper position above the flip-frame and the flip-frame is to rotate each side of the shipping container quadrangular surfaces to become parallel to the automatic spray guns for spraying process.

The Chain Drive

Chains normally have lesser weight as compared to their counterparts such as gear drives or belt drives [1]. Slip might occur on belt and rope drives but chains are used to prevent slipping. Many stiff links are used to make chain; these links are connected through pin joints to allow required

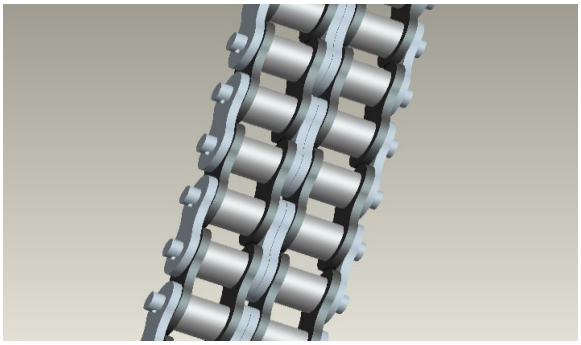

Figure 3: Double-strand roller chain

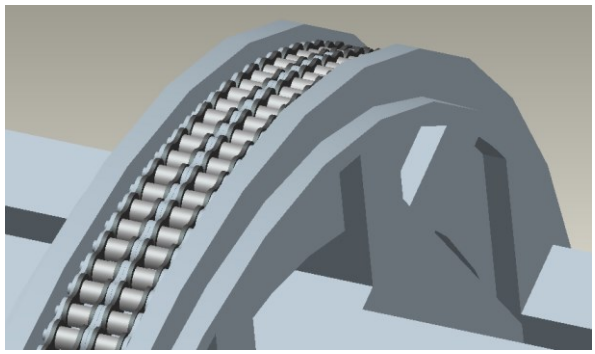

Figure 4: The double-strand roller chain wound round the flip-frame.

flexibility for rolling around the driving sprocket (see figure 3).Hence this design chooses to make use of roller chain drive system in order to maintain high tongue required to rotate the flip-frame mechanism and also to avoid slipping which is common with the belt drive system [2].The figure 4 below show the double-strand roller chain of ANSI No.240 wound round the flip-frame.

Chain drive design calculations

From the above figure 5, the base radius of the flip-frame is given as R, while the roller link radius of the chain drive is r.

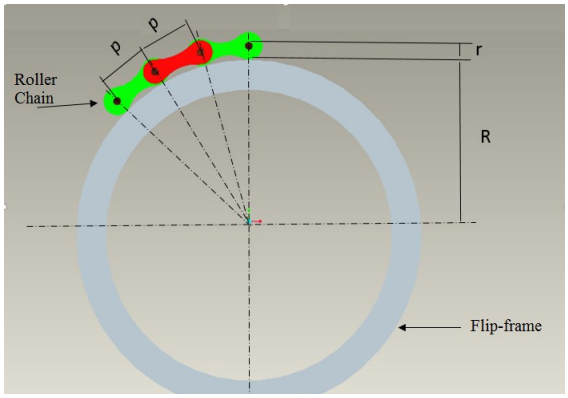

Figure 5: Front view of the flip-frame and the roller chain.

Pitch radius,R^*, of the flip-frame,

$$R^* = R + r \quad (1)$$

Using ANSI Chain No. 240,

Pitch, $p = 24 \times 3.175 = 76.2$ mm (2)

$$Roller\ link\ plate\ height, H_r$$

$$H_r = 0.95p \quad (3)$$

Substituting (2) into (3),

$$H_r = 0.82 \times 76.2 = 72.39mm$$

Roller link plate radius, r

$$r = \frac{1}{2}H_r = \frac{1}{2} \times 72.39 = 36.195mm$$

But Base radius of the flip-frame. R

$$R = 2370.5mm$$

Hence, pitch radius R^*

$$R^* = 2370.5 + 36.195 = 2406.695mm$$

$$Pitch\ Circumference, C_p = 2\pi R^*$$

$$C_p = 2 \times 3.142 \times 2406.695 = 15121.710mm$$

Number of pitches, P_n

$$P_n = \frac{Pitch\ Circumference}{Pitch\ length}$$

$$P_n \simeq 198\ pitches$$

Roller diameter, R_d

$$R_d = \frac{5}{8}p = \frac{5}{8} \times 76.2 = 47.625mm$$

Roller diameter, R_w

$$R_w = \frac{5}{8}p = \frac{5}{8} \times 76.2 = 47.625mm$$

Pin diameter, P_d

$$P_d = \frac{5}{16}p = \frac{5}{16} \times 76.2 = 23.8125mm$$

$$Thickness\ of\ inside\ and\ outside\ link\ plate, t$$

$$t = \frac{1}{8}p = \frac{1}{8} \times 76.2 = 9.525mm$$

$$Pin\ link\ plate\ height, x$$

$$x = 0.82p = 0.82 \times 76.2 = 62.484mm$$

Sprocket design

There were various factors such as, number of teeth on sprocket, chain pitch and roller diameter, which play important role in the designing of sprocket teeth. Tooth profile was designed according to ANSI Standards.

Since

Since Chain pitch =p, Number of teeth = N,

$$Roller\ diameter = R_d, and\ \ Seating\ curve\ diameter, Ds$$

$$Ds = 1.0005R_d + 0.003$$

$$Radius, R = Ds/2 = 0.5025R_d + 0.0015$$

Pitch diameter of Sprocket, $PD = \frac{P}{\sin\left[\frac{180^o}{N}\right]}$

Keyword: LTCC technology; sintering; shrinkage; control methods；

Abstract: As a new integration and packing technology, the low temperature co-fired ceramic (LTCC) technology attracts close attention for its excellent advantages such as high speed transfer characteristics, high reliability, miniaturization, etc. However, the sintering shrinkage of LTCC substrate always affects the practical effect of it. In this paper, the material characteristics, methods to control the sintering shrinkage of LTCC substrate and the development trend for the control methods are mainly overviewed. It is contributed to the research and application of LTCC technology.

Introduction

LTCC technology is a new material technology which can co-fire ceramic dielectric materials with low melting point and high resistivity metal under low sintering temperature. It combines the advantages of High temperature co-fired ceramic technology and thick film technology [1] and has more obvious cost and integration advantage in the design of multilayer circuit modular [2]. It helps to the miniaturization, lightweight and multi-functionalization of electronic components and assembly module and has a very broad application prospect [3-4].

In LTCC technology, the co-firing of low melting metal and ceramic dielectric materials is very important and it directly affects the final quality of the products. To acquire good sintering effect, the co-fired materials are often required to have good co-firing compatibility. However, the shrinkage of LTCC substrates is always a problem in the practical application.

Shrinkage of LTCC substrate

Compared with other material packaging technology, LTCC technology is an ideal packaging scheme with obvious advantages and potential. But the shrinkage of LTCC substrate always occurs in the sintering process [5-8].

In the application of system with high integrated and performance, because of the small distance among the wirings on the low temperature co-fired ceramic substrates, it's very strict with the deformation of sintering. And the sintering shrinkage of ceramic substrates will affect the alignment of signal and ventilation holes. Moreover, the consistency of sintering shrinkage rate also has much effect on yield and properties of products.

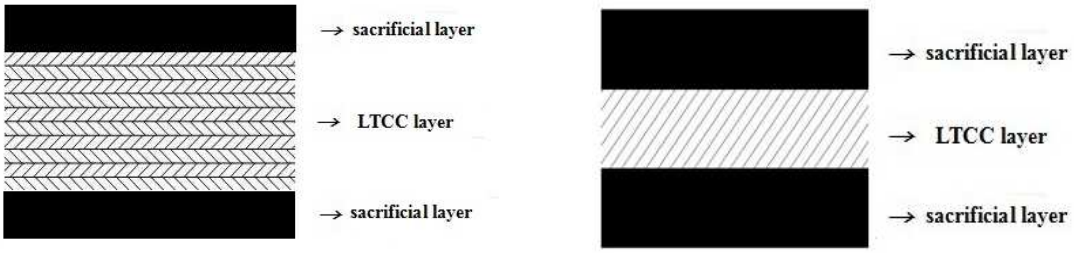
Methods to control the sintering shrinkage of LTCC substrates

Till now, methods to control the sintering contraction are always reported. The methods are mainly done through the control of sintering process, without pressure assisted sintering, pressure assisted Sintering, self constrained sintering, sintering with sandwich structure are all belong to this style and feasible to the practical application[9-15].

(1) Without Pressure Assisted Sintering

This method was firstly developed by DuPont Company of America and the principle is shown in Figure 1. In the process of LTCC substrate lamination, it always has a certain thickness of porcelain as sacrificial layer in the bottom and top respectively and then sinter the whole component.

The sacrificial layer is always alumina raw tape, so it won't shrink during sintering and will leave enough space to discharge the binder in LTCC green tape. During the sintering process, the friction between LTCC substrate will restrict the shrinkage of LTCC substrate in the X-Y direction, so the shrinkage only occurs in the Z direction. The shrinkage rate of LTCC substrate with this method is less than 0.2% in the X-Y direction and the consistency error is less than 0.05%. After sintering, special process is used to remove the sacrificial layer [16].



（Before the sintering） （After the sintering）

Fig1 Diagram of Without Pressure Assisted Sintering

(2) Pressure Assisted Sintering

This method overlies a layer of porous plate on each side after overlying sacrificial layers on both sides of LTCC substrate and then sent to a special sintering furnace for sintering. During sintering, uniaxial pressure will be given in the vertical direction of LTCC substrate (as shown in Fig.2) to increase static friction between LTCC substrate and sacrificial layer in the horizontal direction and the shrinkage of LTCC substrate in the X-Y direction is restricted. By using Pressure Assisted Sintering method, the sintering shrinkage can be reduced to less than 0.05% and the consistency error is less than 0.008%. The sintered LTCC substrate has high density and almost no defects. But the cost of production is much high.

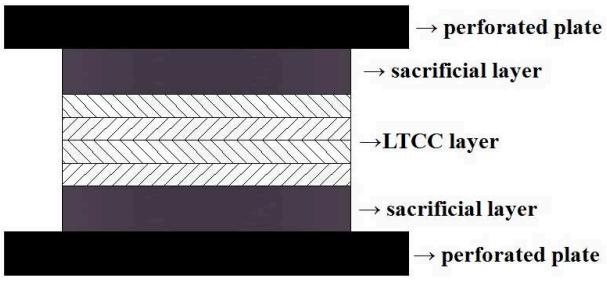


Fig 2 Diagram of Pressure Assisted Sintering

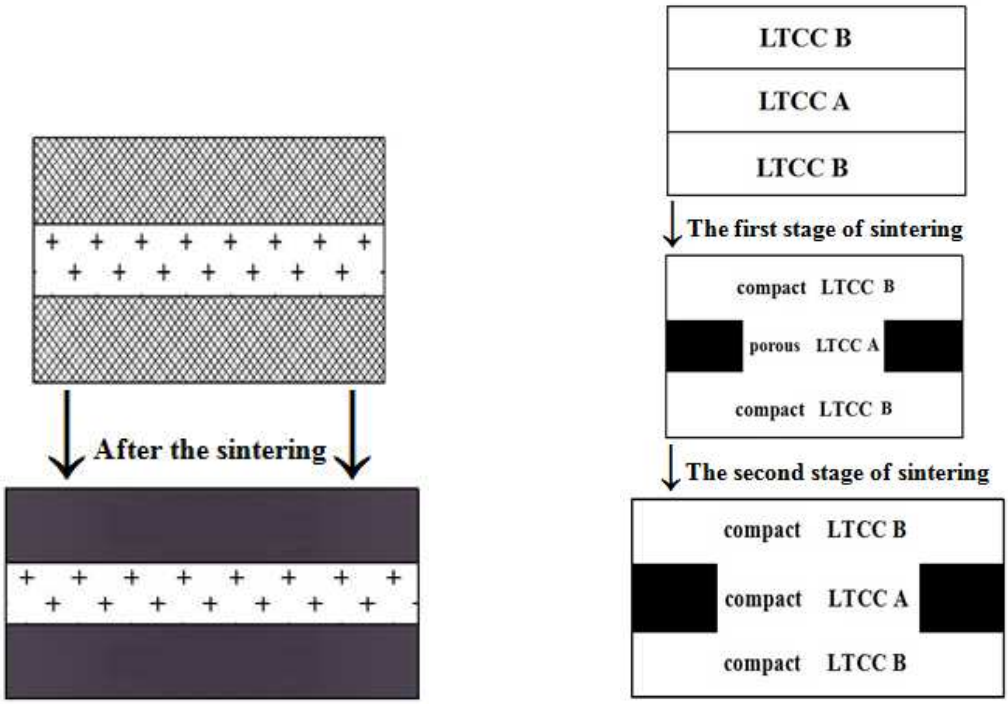
(3)Self Constrained Sintering

Self Constrained Sintering is the method which uses the characteristics of LTCC substrate to inhibit the shrinkage in plane direction. This method can present free sintering to realize the zero shrinkage of LTCC substrate in horizontal. And it is compatible with existing LTCC manufacturing process and equipments, even the conventional LTCC substrate or which with cavity can satisfy the requirements of substrate interconnection. According to the latest research results, the sintering shrinkage of Self Constrained Sintering can be reduced to less than 0.2% and the consistency error is less than 0.02%.

(4) Sintering with sandwich structure

Shrinkage LTCC substrate with sandwich structure is developed by Heraeus company of Germany. This structure is also divided into three layers. Up-down layers are mixed with glass and ceramic, the middle layer is oxidation porous medium (as shown in Fig 3). During sintering, porous

medium of middle layer is required sintered firstly, kept high mechanical strength in the heat and can resist the contraction stress of layers on both sides. As sintering, the glass of up-down layers and ceramic composites start to melt and has a series of chemical reaction with Al_2O_3. When the fluid viscosity of glass decreases to a certain value, it will penetrate into the porous structure of the middle layer. So it should leave enough space for glass fluid infiltration after the middle layer is sintered. Then we can get compact and zero shrinkage LTCC substrate. Study shows that the properties of this LTCC substrate material related to the invasion of the melted glass. So decreasing the melt viscosity of glass as far as possible and reducing the content of glass and choosing proper particle size of Al_2O_3 powder in middle layer can all enhance the invasive to improve the performance of LTCC substrate.



(a) Sandwich structure (b) Sandwich structure

Fig 3 Diagram of two different structure of LTCC sintering

Conclusion

LTCC is a key technology in the field of microelectronics with multilayer and ceramic packaging. The process is very difficult involving many theoretical problems and the substrate shrinkage is the important one for the research and application. The control methods for LTCC substrate shrinkage is in ceaseless development. In the future, more comprehensive methods contains the preparation of material itself is a feasible direction.

Abstract. Crankshaft is the critical component of the drive system of drilling pump. A new state feature extraction method for crankshaft based on operational deflection analysis is presented in this paper. The superiority, feasibility and validity of the system deflection analysis method are figured out with comparison of traditional methods. The vibration deflection technique can supplement with the time-frequency variation of key parts of the crankshaft for the normal measurement information on which the system fault diagnosis is processed. The process illustrates that the method of vibration defection analysis can extract the working state feature entirely and accurately, while provide the valid support for the corresponding fault mode recognition.

Introduction

Crankshaft is the critical component in the drive system whose working state directly affects the overall performance of drilling pump, which is a complex reciprocating mechanical system with a large number of unknown information, whose structural feature and the non-stationary and nonlinear feature of the vibration signal determine the conventional vibration monitoring and signal processing methods are difficult to achieve the anticipated target [1]. Research on fault diagnosis method of reciprocating machinery and equipment on vibration monitoring and analysis aims at two key domains [2, 3]: the accuracy acquisition of the vibration signal and the common character recognition of the reciprocating mechanical failure modes. The former is the basis and prerequisite for accurate fault diagnosis, limited by the actual working conditions or present monitoring tools, the vast majority of data information based on vibration information is only a finite number of vibration monitoring source, which fundamentally limits the accuracy and practicality of fault diagnosis. Hence, enriching vibration data acquisition means and improving the multi-directional vibration signal analysis means becomes particularly necessary. For the latter domain, the research that aiming at the single type of reciprocating machinery has begun, but the method of fault pattern matching is not equipped with effective universality and generality.

The analysis method of operational deflection shape with finite vibration monitoring data as input in monitoring and fault analysis for machinery and equipment system, by the establishment of the vibration model of the system, considering the actual shape of the device under test as a whole or its key components, providing the means and basis for the final precision fault diagnosis. Currently, the research and application of vibration deflection technology is limited in the structure or typical running equipment systems, such as the static and dynamic testing of a car, while general running equipment system is still for exploratory research [4, 5].

Vibration deflection analysis method is applied to the field of the crankshaft of reciprocating machinery fault diagnosis, in which the multi-channel vibration signal frequency information is made full use as input for system fault diagnosis, as the result, the accuracy and comprehensiveness of the information is ensured, while the precise monitoring of the reciprocating machinery vibration and the accurately find of the failure modes is achieved. The research may provide a new train of

thought for finding the common characteristic of reciprocating machinery vibration and fault diagnosis.

Basic principle of operational deflection shape

In ODS process, a series of the vibration measurement signal is input for analyzing the actual working vibration deformation of the system, and the output is the operational mode of the moving facility, by which the quantitative analysis for the working conditions of the system is achieved. The key technique is to carry on dynamic processing for the vibration conditions of the mechanical system [6, 7]. The advantage in the qualitative or quantitative vibration analysis when the system input cannot be determined and its output is the modes of the dynamic equipment system operation is highlighted, including the vibration of a machine, structural or where the excessive vibration level occurs. Fault source can be located through vibration deflection analysis and the transmission route can be judged for the correlation study between the various subsystems of the vibration excitation [8].

Excitation vector is replaced by a certain point response of vibration system in the ODS dynamic treatment, and the transfer function is a point of the response and the reference point response ratio of the vibration system [9]:

$$\{T_{ij}(j\omega)\} = \frac{\{x_i\}}{x_j} \tag{1}$$

where $T_{ij}(j\omega)$ is the relative value of the ODS; x_i is the response of a measuring point (ODS absolute value); x_j is the response of a reference point (ODS reference value).

Coherence function method is applied in quality inspection which is analyzed by ODS; the coherent function can be expressed as:

$$Y_{ij}^2(\omega) = \frac{|G_{ij}(\omega)|^2}{G_{ii}(\omega)G_{jj}(\omega)} \tag{2}$$

where $G_{ij}(\omega)$ is the cross power spectrum between $X_i(\omega)$ at reference point i and $X_j(\omega)$ at measuring point j, and $G_{jj}(\omega)$ is the power spectrum of $X_j(\omega)$ at the measuring point j.

The absolute value of ODS of every measuring point and simulating point can be obtained by Formula (1) and reference the effective value of the power spectrum [10].

$$\{X_i(\omega)\} = T_{ij}(j\omega)\sqrt{G_{jj}(\omega)} \tag{3}$$

Compared with the experimental modal analysis, ODS analysis have several superiorities. First of all, its foundation is from uncertain outside incentives. The result of the ODS analysis changes with the incentive which not only associates with the system itself, but also depends on the external excitation. Secondly the ODS dynamic treatment can obtain the measurement frequency under different working conditions, and build the corresponding relationship with the external excitation individually. Finally, the frequency component from sensor signal is set as the research object in the ODS analysis, while the target is the vibration characteristics in case of the unknown system excitation.

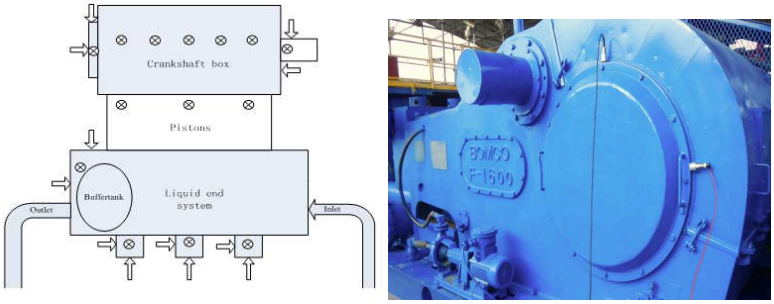
Vibration measurement and analysis

(1) Vibration measurement

The corresponding physical model of the drilling pump is established on which the vibration testing point is projected as shown in Fig.1 (a). The practical testing points mainly locate at crankshaft bearings, crankshaft outer layer, pistons and fluid end, from which the signal may use for supplement proof.

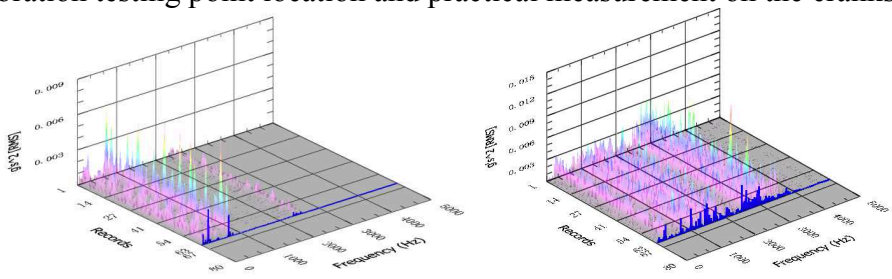
Fig.1 (b) shows that the radial vibration of the crankshaft cap end is measured. The practical vibration signal including normal in Fig.2 (a) and abnormal in Fig.2 (b) is preliminarily analyzed.

Compared with the former, the abnormal time-frequency signal is disordered with greater vibration amplitude from 2 to 10 G and more complex frequency distribution, in which the lower band is similar while the higher is obviously distinct. The initial analysis illustrates the fault of crankshaft system to certain extent which needs deeper analysis for accurate systematic diagnosis. The Local Wave Method is employed in time-frequency analysis as the base and supplement of systematic vibration deflection analysis.



(a) (b)

Fig.1. Vibration testing point location and practical measurement on the crankshaft



(a) (b)

Fig.2. Time-frequency analysis of vibration signal comparison

(2) Local wave time-frequency spectrum analysis

Local Wave Method is a self-adaptive analysis method for mechanical signal of non-stationary and non-linear which is established on the instantaneous frequency. By Local Wave Method, the vibration signal is decomposed into IMFs which can meet suitable conditions. These IMFs are analyzed through Hilbert transformation, as the result, the instantaneous frequency and time-frequency character of the vibration signal are extracted, as so-called local wave time-frequency analysis. By Local Wave Method, the original signal is decomposed into IMFs and residual component which is an average trend or a constant. After the Hilbert transformation for each IMF, the signal data can be expressed as Formula (4):

$$X(t) = \sum_{j=1}^{n} a_j(t) e^{i\omega_j(t)t} \tag{4}$$

where $a_j(t)$ is the instantaneous amplitude, $\omega_j(t)$ is instantaneous frequency. Virtually, the signal amplitude can be expressed as both the function of time and instantaneous frequency in 3-dimensional space and contour lines in time-frequency plane, while the amplitude distribution in time-frequency plane can be defined as local wave time-frequency spectrum.

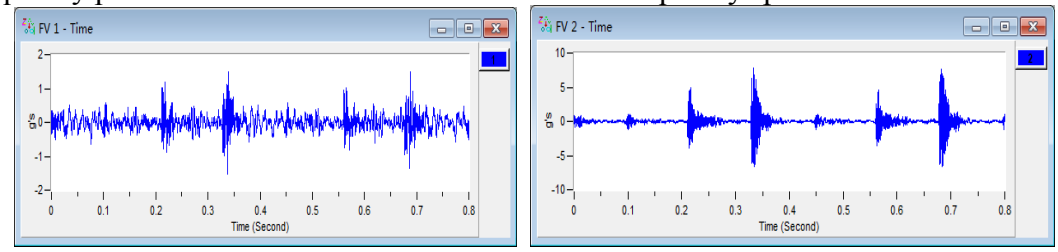


Fig.3. Practical measurement vibration signal of two edges of the crankshaft

The time-domain signal of the both crankshaft end is shown in Fig.3. By Local Wave Method the signal is decomposed and the time-frequency spectrum is obtained respectively as shown in Fig.4. The two signals contain apparent features, including time domain and frequency domain which can be quantitatively analyzed for accurate fault diagnosis.

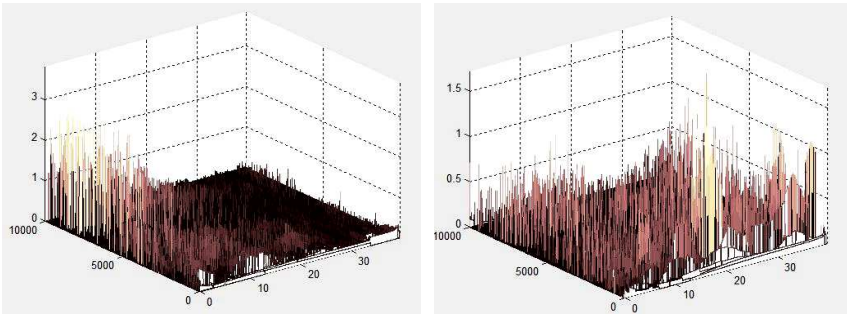

Fig.4. Local wave time-frequency spectrum of the two measurement points

(3) Overall ODS analysis

Set the real measured vibration signal as the input of the entire vibration deflection model, the ODS simulation is processed as shown in Fig.5. Thus the vibration information of the critical point is achieved, whether from the real or the analog. The local wave time-frequency analysis method is applied in revealing the energy gray level distribution of the characteristic frequency bands as list in Tab.1, while the corresponding frequency bands comes from reference [2] in which the author gives the entire experiment process and the final conclusion of the specified type drilling pump: band 1 is 0-200Hz for driven mechanism, especially for bearings, band 2 is around 1000Hz for crankshaft and bearing bush, band 3 is around 2000Hz for plunger system and band 4 is around 2500Hz for liquid end of the pump. The time domain signal and local wave time-frequency spectrum of the max vibration severity point in Fig.6 reveals the impact character of concentrated spectrum energy distribution.

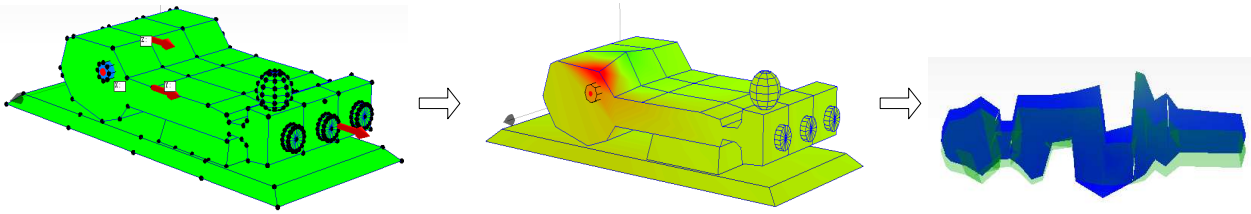

Fig.5. Drilling pump operation deflection when the crankshaft in abnormal load system

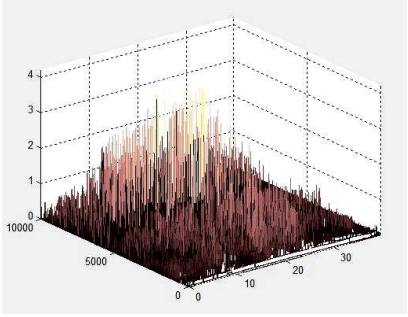

Fig.6. Local wave time-frequency spectrum of the max vibration severity point

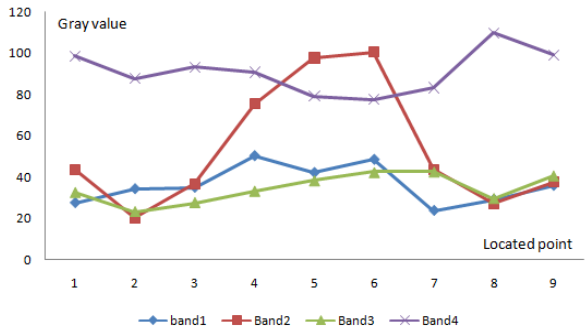

Fig.7. Energy gray value variation trend of the crankshaft located points

Fig.7 shows the variation trend of the characteristic frequency bands, while the variation of band 2 is obvious in the located point of the crankshaft. The entire energy gray level fluctuation illustrates the working state of the crankshaft system.

Tab.1. Energy gray value of the ODS analysis for part of crankshaft measured and analog points

Number	Measuring point	Type	Direction	Band1	Band2	Band3	Band4
1	Crankshaft end cap axial	Measured	1z	27.6	43.63	32.55	98.65
2	Crankshaft end cap vertical diameter	Measured	1y	34.36	20.17	23.22	87.83
3	Crankshaft end cap horizontal radial	ODS	1x	35.06	36.5	27.66	93.22
4	Crankshaft central axial	ODS	2z	50.44	75.48	33.18	90.71
5	Crankshaft central vertical diameter	ODS	2y	42.24	97.58	38.28	79.17

7	Belt wheel end axial	ODS	3z	23.78	43.67	42.55	83.12
8	Belt wheel end vertical diameter	Measured	3y	29.2	27.22	29.58	109.83
9	Belt wheel end horizontal radial	ODS	3x	35.96	37.5	40.66	99.26

Note: testing direction x presents horizontal, y is vertical and z is axial.

Conclusion

With finite vibration information as the input of the vibration deflection analysis method, the result of the multichannel analog acquisition vibration signal analysis is achieved on which the vibration detection and feature extraction for the crankshaft of the drilling pump is completed with the intelligent recognition on the system fault source and mode. The dynamic analysis contributes to the solution of the full vibration analysis of the critical components in the moving equipment system. The required vibration information of key locations can be achieved from the information of several experimental measurement points, hence the problems such as inadequate information and inaccurate analysis of the fault diagnosis in the complicated mechanical system can be solved, by which the foundation of accurate fault diagnosis process is established. The experimental research process of the typical case testifies the feasibility of the method, which provides a reference for the visualization monitoring and sophisticated fault diagnosis for large reciprocating mechanical system.

Keywords: Vibration;Hydraulic Vibration Exciter; Displacement Response; Hydraulic System

Abstract. Pressure of the liquid is used as power source of hydraulic vibration exciter. Rotary directional control valve is the realization of oiling-way veversing components . The piston is reciprocated under the influence of the change of the hydraulic. The reciprocating movement of the piston is a result of fluid pressure.Working area of the piston multiplied by the pressure of the liquid is equal to the thrust of the piston.Displacement response of the vibration exciter can be simplified to the second-order vibration systems.Elastic beam is used as limit components of piston of vibration exciter,the piston vibration waveform is a sine wave .The volume of elastic beam is smaller than the volume of fluid elastic element . The hydraulic circuit is a dual pump fuel supply circuits.Pumps are used to supply rotary valve and hydraulic cylinder .Dual pumps fuel supply system is conducive to control fluid pressure and flow of the rotary valve and vibration piston.

Introduction

Vibration process is widely used in machinery manufacturing cold areas such as cutting, grinding , broaching and other aspects of the application in precision machining and processing vibration machining difficult materials have unique advantages. But drawing, trombone success in laboratory testing in the processing of plastic materials only . There are two characteristics of vibration processing :. A cutting speed v <2πfx. energy b. cutting needed is provided by the vibration exciter . cutting machining to provide a non-vibrating energy only for feeding speed

Ultrasonic vibration has been applied in cold areas , but the characteristics of plastic processing metallurgical enterprises is power, can not use ultrasonic vibrations. Hydraulic vibration exciter can produce high- vibration energy.

Constitutes a principle of hydraulic vibration exciter

Hydraulic vibration exciter constitution principle as shown. Vibration exciter mainly consists of three parts , cylinder, rotary valve and elastic beam 1. The rotary valve rotated by a hydraulic motor. Valve spool in the rotational direction of the circumference of the radial oil grooves . Realization of the oil tank is arranged alternately commutation purposes.

Right chamber of the piston by the oil pressure force F1 acts , leftward , when changing the oil pressure to the oil chamber with the port is turned on, and the piston into the left chamber of the high pressure oil passage on state, since the pressure receiving area of the piston about the type , the piston by right hydraulic force F2 , the piston moves to the right [1].

The elastic beam is an essential element to ensure continuous operation of the hydraulic exciter . Due to intermittent supply cylinder valve cavity left low and high pressure zones in changing . Eventually left cylinder piston reaches the surface caused by vibration dead . Elastic beam is maintained at a certain piston position . Rigid beam reach vibration requirements , elastic stiffness K is too small , it becomes flexible beam limit would not achieve the role . Therefore, the design of the elastic beam stiffness values according to the force of the hydraulic piston vibration exciter determined to achieve the purpose of the piston vibration .

The force on the piston shown in Figure 2.

F (t) periodic force can be decomposed into two components, namely the constant component and periodic component:

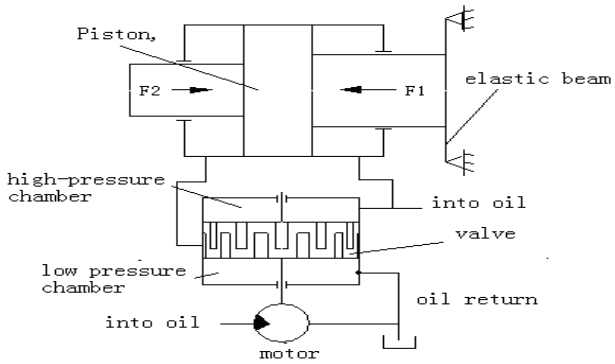

Fig. 1. Schematic of hydraulic vibration exciter constitute

Constant component: $F_0 = \frac{1}{2}(F_1 - F_2)$

Periodic component: f (t)

The same component can only make the piston produces the static displacement, cannot make the piston vibration, f (t) to make the piston vibration cycle components only, the Fourier series expansion cycle component[2]:

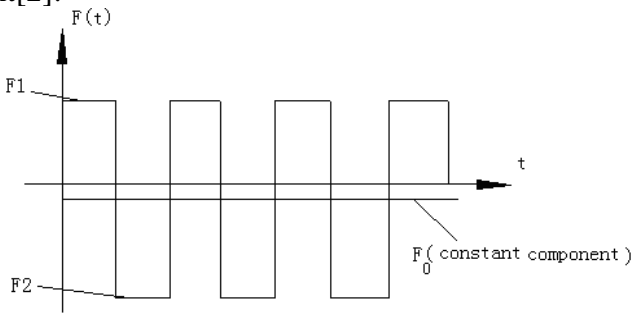

Fig 2. Pistons by trying

$$f(t) = \frac{4F}{\pi}\sum_{n+1}^{\infty}\frac{1}{2n-1}\sin(2n-1)\omega t = \sum_{2n-1}^{\infty}\frac{4F}{\pi i}\sin(i\omega t) \quad (1)$$

Because the system is linear, the piston in f (t) under the action of the displacement response of x (t) is equal to f (t) separate the components in the system response superposition, namely

$$x(t) = \frac{4F}{\pi}\sum_{i=2n-1}\frac{\beta_i}{i}\sin(i\omega t - \varphi_i) \quad (2)$$

Type: β i—i order harmonic component of vibration amplification factor

φ_i —i order harmonic component phase lag Angle

ω - vibration frequency

Due to the phase Angle of each harmonic component is different. The displacement response of x (t) waveform is different from the waveform of exciting force F (t).The displacement response waveforms of x (t) depends on the system the value of the parameter m, K and C each order harmonic response amplitude x_i.Easy to prove that: the $x_1 >> x_2 >> x_3 >>\cdots x_{n-1} >> x_n$, that is to say, the displacement response of x (t) more than three times harmonic component are small and can be left out, then

$$x(t) = \frac{4F}{\pi}\times\frac{1}{2\xi K}\sin(\omega t) \quad (3)$$

Type: ξ -damping ratio, K - elastic beam stiffness.

For frequency ratio r= $\omega / \omega_0 > 0.7$, the above conclusion is reasonable. So there are

$$x(t) = \frac{4F}{\pi}\beta \sin(\omega t - \varphi) \tag{4}$$

$$Type: \beta = \frac{\frac{1}{K}}{\sqrt{(1-r^2)^2 + (2\xi r)^2}}$$

$$\varphi = \arctan[-\frac{2\xi r}{1-r^2}]$$

Indicates that the vibration of the piston is sinusoidal vibration.

To two things: a. If not set elastic beam when the piston under the action of force of F1 and F2, overcome damping, soon arrived at one end of the cylinde.The directional control valve has not been reversing, the piston has reached the end. The oil cylinder end cover is the rigid body k=∞.Therefore the piston is not moving.

Setting elastic beam bearing, the piston force under the action of F1 and F2, overcome damping work, one side will be part of the work shift as the elastic deformation of beam power storage. When reversing the deformation of elastic beam work and released and the effect of hydraulic power superposition, accelerate the rate of movement of the piston.

Another function of the elastic beam is on the limit of piston. The piston vibration is always in a certain position. Meanwhile elastic beam should be set at the side that force is small,so that the elastic beam during the vibration exciter is always in force pressing the state to prevent it from loosening and useless.

b. The elastic beam compared with oil spring. If the oil spring as the elastic element, in order to obtain sufficient elasticity deformation, on both ends of the cylinder should be set up two large piston. And elastic beam is used as the elastic element structure of small dimension, small volume.

The hydraulic system design

Hydraulic vibration exciter hydraulic circuit design problem to consider is the hydraulic motor and speed control and stability of the oil cylinder. Under normal circumstances, the shear vibration or vibration frequency stability requirement when processing in a certain range, hydraulic motor rotation speed can be controlled, the vibration frequency of controllability.

Vibration process similar to the requirement of vibration amplitude is set in a certain range, the vibration amplitudes are not affected by the interference of mechanical feed speed, namely input cylinder liquid flow rate and velocity control requirements. Vibration amplitude with the rotary valve guide groove is proportional to the oil on time. Rotary valve low rotating speed of cylinder vibration amplitude. Rotary valve of high rotational speed is the vibration of the cylinder small amplitude.

Supply oil to the vibration piston hydraulic motor and oil pump, piston of hydraulic oil demand is related to the vibration amplitude and vibration frequency. Through the throttle valve and the adjustment of speed regulating valve under the condition of its vibration frequency determine to achieve more precise amplitude. So the piston vibration amplitude control requirements are within a small range. Amplitude control to conform to the requirements of machining accuracy.

According to the design requirements of the above design of hydraulic system are shown in figure 4, hydraulic motor oil supply loop[4]. The hydraulic oil filter through to arrive at the pump. Relief valve installed in the pump is used to control the export of oil pump oil supply pressure and pressure of the hydraulic system. Oil flows through the one-way valve, the two two-way valve, control valve to hydraulic motor. Pressure gauge installation position should be at the side of the overflow valve, adjust the pressure can be easily observed when the hydraulic pump output pressure. Pressure gauge is installed on the back of the check valve can be closer to the real working pressure of hydraulic system. At the same time can be indirectly detect the working state of the check valve.

The basic composition of the hydraulic cylinder oil supply loop is the same as the hydraulic motor oil circuit. Add an accumulator in hydraulic circuits. To meet the requirements of vibration oil cylinder of flow fluctuation. Graphical position has always been the oil chamber of hydraulic cylinder of high pressure oil chamber. Inferior vena is realized in conversion between high and low pressure piston to move up and down. Due to the same shape guide groove, so the piston displacement of moving the same amount[5].

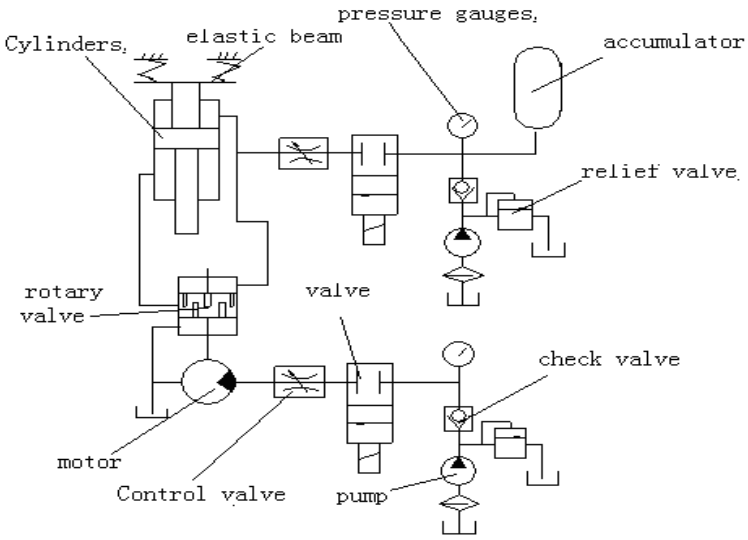

Fig 3.Hydraulic system

Conclusion

Hydraulic vibration exciter is hydraulic circuit by using the rotation type directional control valve, the direction of the transformation. According to the piston stress cycles using Fourier series expansion is derived by reasonable simplification of the vibration exciter displacement response expression. The hydraulic vibration exciter can be thought of as the second order vibration system. The vibration of the piston is a sine wave.

The piston of hydraulic vibration exciter adopted elastic beam as a limit switch. Compared with the oil elastic element elastic beam, the small size. Elastic beam in the application of the vibration exciter is piston vibration components is a must.

Oil supply loop hydraulic circuit with double pump, used for rotary valve and hydraulic cylinder oil supply. Double piston pump oil supply system is advantageous to the rotary valve and vibration of the regulation of the oil pressure and flow rate. Speed regulating valve of flow control accuracy is more advantageous to the working stability of vibration system.

Keywords: Steam turbine blade, Circular cutter, Envelope machining, Cutter contact, Surface reconstruction, Residual height, Tool path

Abstract: In order to solve the problem of poor steam turbine blade processing efficiency, and on the basis of analyzing the turbine blade surface and the existing processing methods, a model of circular cutter turbine blade machining is built. By comparing the tool paths of horizontal and vertical section envelope machining, choosing quasi-vertical cross section envelope machining method and utilizing the original datum and NURBS surface matching mathematic methods, this paper provides an algorithm of residual height calculating, and based on this, the tool path can be planned. Datum show that, the tool path of circular cutter machining blades is much longer than the tool path of ball-end cutter envelop milling machining blades, and the machining efficiency is also highly enhanced.

1. Introduction

Steam turbine blade is the key part of a steam turbine, which can turn heat energy of the steam and gas into mechanical energy directly. Steam turbine blade is also an important and most widely used component in steam turbine. There are thousands of blades in one steam turbine. The processing requirements of blades is strict, the workload is heavy, the processing quality requirement is high, and the workload of blades machining accounts for one fourth to one third of the total steam turbine workload. Practice indicates that the design and manufacturing level of the blade is one of the important indicators to measure turbine technology. Blade manufacturing efficiency directly influences the turbine manufacturing cycle, and manufacturing quality directly affects the operating efficiency and the safety of the steam turbine unit, that is why improving the machining efficiency and machining precision of the blade becomes one of the important research among scholars and engineering technicians at home and abroad.

In order to obtain high efficiency of numerical control machining tool path, many scholars have carried out studies and put forward a variety of algorithms. Someone has put forward the method of using parallel machine tool to do the blade machining [2] , but because of the processing method which uses ball-end cutter to do machining on the four-axis or five-axis numerical control machine tool, the target of improving processing efficiency is limited. In this paper, based on the analysis on the surface of the blade, the method of circular cutter turbine blade machining is presented, and the mathematical model of blade surface reconstruction is established, and by controlling the residual height, turbine blade machining tool path is planned on this method.

2.Processing Object Analysis

2.1Blades Types

Steam turbine blades include constant chord blade and variable chord blade, the former can be achieved by molding or contour machining to meet the processing requirements because of the simple mechanism. Variable chord blades include variable cross-section straight blades and variable cross-section twisted blades. Variable cross-section straight blades, the blade section shape is changing along with the height, and there is no reverse between adjacent two sections, and forming milling cutter can be used for oblique milling; Variable cross-section twisted blade, Variable cross-section twisted blade, namely with the blade height changing, cross-section shapes are different, and adjacent two sections are twisted, and due to its high efficiency, this method is widely used [3].

2.2Blades Composition

The research object of this paper is the rotor blade on steam turbine rotor, whose structure contains blade body, blade root and blade shroud [4]. Blade body is the basic working part of blade, whose structure is complex. And most of blade bodies are torsion free surfaces. Blade body is composed of concave side, convex side, gas inlet side fillet, gas outlet side fillet, blade root fillet, blade shroud fillet and lacing wire. The function of blade root is to fasten rotor blade, in order to prevent it from dropping from the rim groove under the high pressure of driving force and rotating centrifugal force. The blade root types include fork shape, ladder shape, tenon tooth shape, T shape, mushroom and longitudinal tree shape. The blade shroud is the fixation of the outer side of blade, which usually equipped with shroud ring. The shroud ring can combine several blades together into a blade group.

2.3 Manufacturing of Blade Parts

Manufacturing methods of blade parts include copying method, special processing method and the numerical control milling method. Coping method is the most traditional method, and because of its low efficiency and less accuracy, this method has gradually been eliminated. Special processing method mainly refers to electrolysis processing, which cannot be limited by the hardness of the material, but the bottleneck of this method is its low accuracy and instability of machining process. Ball-end cutter is the most widely used method in modern society.

3.Research on Circular Milling Cutter

3.1 Envelop Machining Model

The model of blade machining with circular envelop milling cutter is shown in Fig. 1. Set up the workpiece coordinate system O-XYZ, while circular cutter moving along X to the opposite blade vertically, the front and back sides moving along Y, and upper and under sides moving along Z. If it is a twisted blade and moves associatively along A, in order to obtain an ideal disc diameter D and cutting state, cutting tool coordinate system can define two location parameters angle B and angle C. During the period of envelop milling, B and C do not take part in associative moving.

3.2 Quasi-Vertical Cross Section Envelop Milling

As it can be seen in the model of blade machining with circular envelop milling cutter, according to different cutting methods, horizontal and vertical cross section envelop milling can be achieved. Seeing from the horizontal cross section, the enveloping principle is shown in Fig. 2. These two methods can be simplified as the enveloping problems of sets of space curves. The difference is, the outline of horizontal cross section envelop milling is a plain curve, while the vertical one is space free curve.

Considering the different sizes of different blade parts, the original datum of blades surface reconstruction are several point coordinates on horizontal cross section. In order to simplify the calculation of tool path and consider the tool path twist state and the different widths of the two sides of the blade, vertical cross section envelop milling can be improved. After improvement, the cutting pattern can be named as “quasi-vertical cross section envelop milling”.

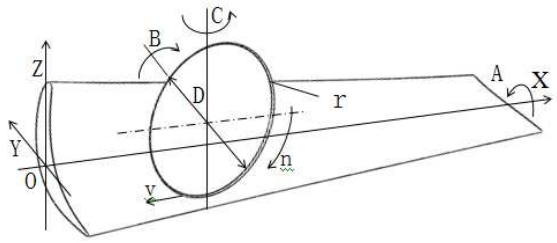

Fig. 1 Envelope machining model

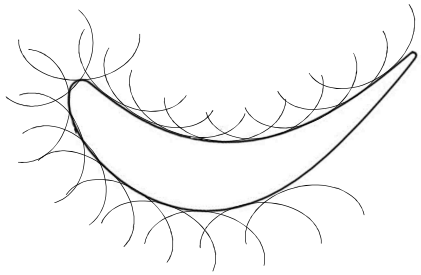

Fig.2 Circular cutter envelope machining sketch

3.3 Interference Discrimination

In the process of steam turbine blade surface machining, due to the complex structure of blade surface, cutter interference is easily happened. The most common situation is: global interference and part interference. Global interference, namely collision interference, means the moving parts of the machine tools or cutters intervene with blade workpiece or fixtures. The mostly happened part of global interference in circular cutter envelop blade milling is blade root, which can be prevented

by adjusting the location parameter of the cutter. But because of the cutter sizes or the unreasonable path planning in the part interference, which will cause overcut or undercut. As to the steam turbine blade, the part inference is mostly happened in the place of blade concave whose curvature is changeful or the part with small curvature radius. The part interference can be prevented by choosing reasonable cutter diameter D.

4.Steam Turbine Blades Surface Reconstruction

4.1Mathematic Model of Circular Cutter

Torus, refers to a ring-shaped surface generated by rotating a circle around an axis that does not intersect the circle**.** Circular cutter refers to the circular surface cutter which is formed in the process of cutting edge machining. As shown in Fig. 3, in the cutter coordinate system $s(o_t xyz)$, circular surface is generated by radius r rotating around an axis z. The path of the circle center o_r rotating around axis z in the plane $xo_t y$ is defined as lead circle. The radius of lead circle, suppose M is a point on the circular surface, the coordinate of M can be expresses as formula 1.

$$\begin{cases} x = (r\cos\alpha + R)\cos\beta \\ y = (r\cos\alpha + R)\sin\beta \\ z = r\sin\alpha \end{cases} \quad (1)$$

In the formula, r is the arc radius of cutter point, R is the radius of lead circle, α is the angle between the joint line of movable point M on circular surface and the circle center o_r and its projection line in plane $xo_t y$, β is the angle between movable point M in the plane $xo_t y$ and axis x.

4.2 Relation between Array Pitch and Residual Height

The array pitch is in co-relation with residual height, actual radius of cutting tool and the partial radius of curvature surface. As seen in Fig. 4, as to the circular envelop milling cutter blade surface, the direction of array pitch is parallel to the blade and perpendicular to the direction of tool path. Given the array pitch L, actual radius of cutting tool R_e, and partial radius of curvature surface R_b, the allowable value of residual height is h, the array pitch and residual height can be expressed as formula (2).

$$L = \sqrt{8hR_eR_b/(R_b \pm R_e)} \quad (2)$$

In the formula, blade concave is negative，the blade convex is positive.

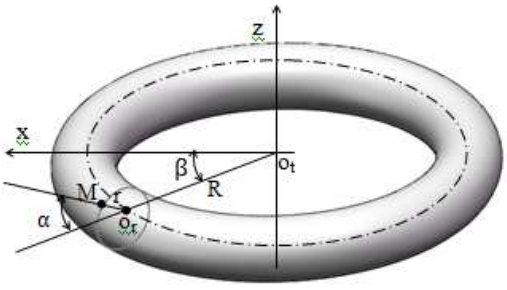

Fig.3 Circular Cutter Structure

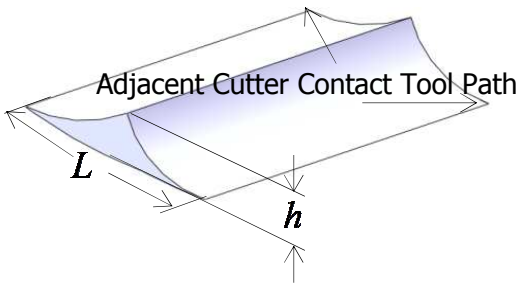

Fig.4 Residual Height

4.3Mathematical Model of Blade Surface Reconstruction

NURBS surface matrix can be seen as the promotion of surface matrix representation, this paper adopts bi-cubic NURBS surface matrix, which is similar to a space surface, $k \times l$ times NURBS surface can be represented as:

$$f(x,y)=\frac{\sum_{i=0}^{n}\sum_{j=0}^{m}\omega_{ij}r_{ij}N_{i,k}(x)N_{j,l}(y)}{\sum_{i=0}^{n}\sum_{j=0}^{m}\omega_{ij}N_{i,k}(x)N_{j,l}(y)} \quad (3)$$

r_{ij} is the control vertex, i,j are sequence numbers of control vertex respectively in x,y two directions. Obviously, the number of control vertices in x,y two directions are $n+1$ and $m+1$ respectively. $N_{j,l}(y)$ is the NURBS curve basis function of l timesin y direction. ω_{ij} is the weight factor of blade surface. Control vertex r_{ij} is the cross point of cutting lines in x,y two directions, namely the cross point of number i cutting line in x direction and number j cutting line in y direction. The corresponding weight factor ω_{ij} of control vertex r_{ij} is some constant greater than zero, when the weight factor grows, the surface will get close to control vertex r_{ij}, especially when weight factor tends to infinity, surface overpasses control vertex r_{ij}.

The rational fractional function of bi-cubic NURBS surface can be expressed(p,q are the substitutions of (i,j)). Through deducing, we can achieve rational fractional function of the number (i,j) surface patch of NURBS surface is Formula (4).

$$f_{i,j}(x,y)=\frac{\sum_{p=i-3}^{i}\sum_{q=j-3}^{j}\omega_{pq}r_{pq}N_{p,3}(x)N_{q,3}(y)}{\sum_{p=i-3}^{i}\sum_{q=j-3}^{j}\omega_{pq}N_{p,3}(x)N_{q,3}(y)}=\frac{N_{i,3}^{x}W_{pq}^{r}(N_{j,3}^{y})^{T}}{N_{i,3}^{x}W_{pq}(N_{j,3}^{y})^{T}} \quad (4)$$

In this formula: $N_{i,3}^{x}=(N_{i-3,3}(x)\quad N_{i-2,3}(x)\quad N_{i-1,3}(x)\quad N_{i,3}(x))$;

$$N_{j,3}^{y}=(N_{j-3,3}(y)\quad N_{j-2,3}(y)\quad N_{j-1,3}(y)\quad N_{j,3}(y));$$

$$W_{pq}^{r}=\begin{pmatrix}\omega_{11}r_{11} & \omega_{12}r_{12} & \omega_{13}r_{13} & \omega_{14}r_{14}\\ \omega_{21}r_{21} & \omega_{22}r_{22} & \omega_{23}r_{23} & \omega_{24}r_{24}\\ \omega_{31}r_{31} & \omega_{32}r_{32} & \omega_{33}r_{33} & \omega_{34}r_{34}\\ \omega_{41}r_{41} & \omega_{42}r_{42} & \omega_{43}r_{43} & \omega_{44}r_{44}\end{pmatrix} \quad W_{pq}^{r}=\begin{pmatrix}\omega_{11} & \omega_{12} & \omega_{13} & \omega_{14}\\ \omega_{21} & \omega_{22} & \omega_{23} & \omega_{24}\\ \omega_{31} & \omega_{32} & \omega_{33} & \omega_{34}\\ \omega_{41} & \omega_{42} & \omega_{43} & \omega_{44}\end{pmatrix}$$

5.Application Examples

Taking a domestic steam turbine low pressure rotor blade processing as an example, the length of the rotor blade is 440mm. The original datum are profiles of 23 horizontal cross sections as shown in Table 1, and the cross section distribution is shown in Fig.5. This paper does some researches on machining with circular milling cutter, utilizes the method of quasi-vertical cross section envelop milling, and discusses from the aspect of surface reconstruction, horizontal and vertical section line interpolation,deciding cutter contact tool path and calculating of cutter location point. As to the blade convex, the arc surface will not be interfered by machining surface, and to the blade concave,the radius of arc surface must be smaller than the radius of the smallest radius of surface.

6.Summary

In the process of steam turbine blades envelop milling machining with circular cutter, the curvature distribution of milling is variable and can fit curvature distributions of all processing surfaces, which shows “curvature match” and good cutting condition. This can help to keep a constant speed of ball-end cutter cutting and prevent the problem of the zero cutting speed of axis of rotation, narrow chip space and cutting angle differences. In the process of machining, the cutter contact point moves along the circular ring successively, which can use the parts wear of the full width cutting tools of circular disc cutter, so as to extend the life of the tools.

Abstract. In order to improve the sealing quality and reduce the labor intensity of people, the stepping motors have been adopted in the salver mechanical transmission part and sealing part of the original sealing machine. In the paper, salver feeding and control system of sealing machine have been designed. The results have been obtained such as control principle diagram of the control system, equivalent circuit diagram and outer wiring diagram of PLC and PLC control program. It can realize the automatic control of the sealing machine. Improved sealing machine has the characteristic of simple mechanical transmission parts, advanced control system, small human error, low fault rate and easy operation.

Introduction

With the development of science and technology and people living standard rise, people is higher and higher requirement for the quality of food and health. Therefore, in order to make our products to seal save, keep the quality of our products and avoid loss of products, the packaging container needs to be sealed.We call it sealing machine that packing container for filling sealing machine. It is a product of The Times. At present there are many kinds of sealing machine. According to the mechanical properties of packaging materials, sealing machine is divided into a flexible container sealing device and rigid container sealing machine. According to the shape of the container, the sealing machine is divided into plastic bags and cup sealing machine. And cup sealing machine is mainly suitable for soybean milk, milk tea and other hot and cold drinks. Because of its simple structure, small volume, and easy to operate, it is widely used. [1]

In the paper, the cup sealing machine has been studied. On the basis of its working principle and structure of the sealing machine, the sealing machine has been improved design, especially for the cup conveying system. The design make it's from a cup of a seal, sealed into four cups can now be done automatically. The automatic control system has been designed to improve the degree of automation, more convenient to use, and make up for the lack of traditional cup sealing machine design.

Structure of Sealing Machine

(1) The structure of original sealing machine [2]: it is mainly by the motor, CAM transmission mechanism, pressure head, conveying mechanism and feeding mechanism through the frame of connection as shown in figure 1.

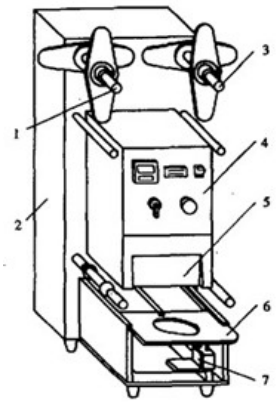

Fig1. Main structures and names

(2) The improved structure

The main body structure of the improved sealing machine is the same as the original sealing machine. In order to improve the sealing efficiency and reduce labor intensity of workers, mainly for the sealing machine tray modification design sections and compressive bar. Part of the ptray is the original c plate, can only send into a cup, manual control; To adopt stepper motor control, can add four cups, automatic sealing processing in turn. Compressive bar part of the original sealing machine adopts lever, manual complete sealing and cutting, the improved using stepper motor, through the control system to realize automatic sealing and cutting.

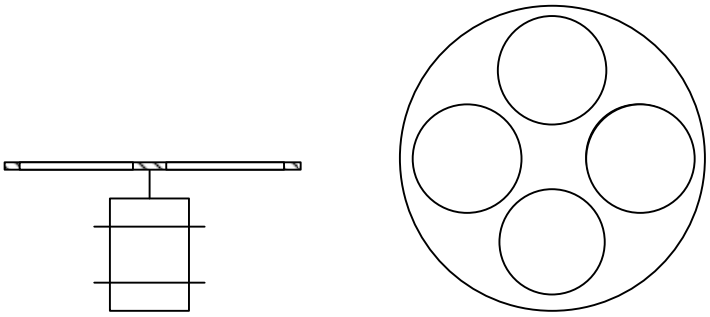

Fig2. Diagram of improved feeding structure

Design of the Control System

3.1 The control principle of sealing machine

Food was packed and into the tray with a piezoelectric sensor. Piezoelectric sensors work and send electrical signals. The electrical signal amplified by amplifying circuit, and the more meet the requirements, the signal is output. PLC input interface 2 received signal, the output interface 2 according to the programmed data output pulse signals. Stepper motor Ⅰ work, began to spin the tray to a fixed position. Detection sensor detects the tray to the specified location, signal. Signal amplifying circuit output signal. PLC 3 received signal input interface, it also control output interface 3 and 4 output interface. 3 according to the programmed output interface data output pulse signal, the stepper motor Ⅱ to complete various tasks (); 4 according to the programmed data output pulse signal output interface, indicating lamp is opened, at this time due to the stepper motor Ⅱ work, manual switch is prohibited to use; Closed detection sensor at the same time, when the stepper motor Ⅱ completion of tasks, light bulbs, open detection sensor. If only to complete a specified task, can be manually switch open stepper motor Ⅰ alone, take out the sealing good items.

Sealing machine control principle diagram is as shown in figure 3.

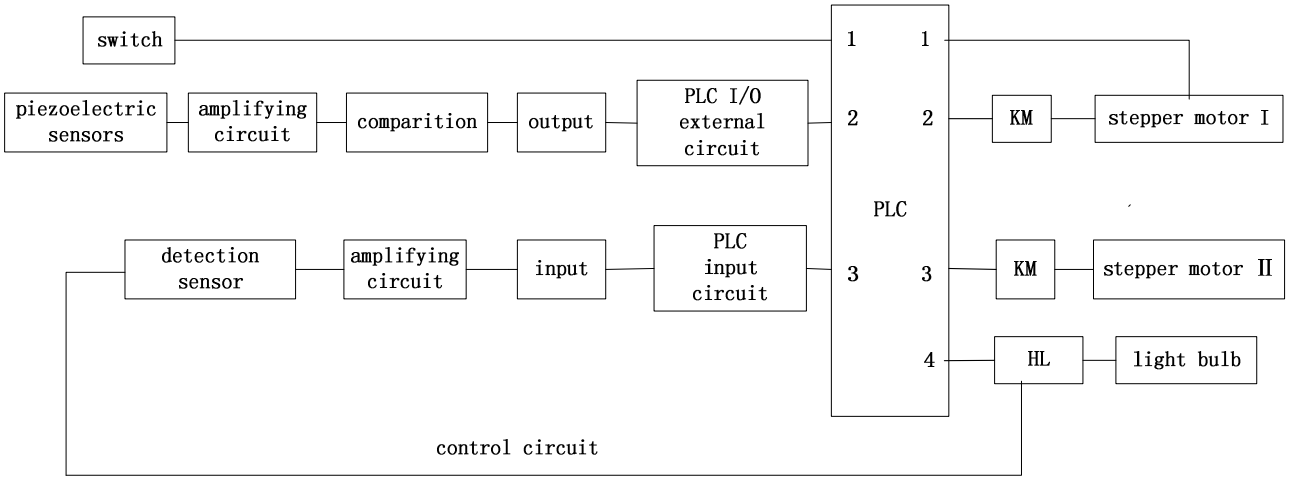

Fig3. Diagram of sealing machine control principle

3.2 The function of the control system

1) The self-check function. Each, the cup packed goods is into the tray, start work, detection sensor detects whether the cup to the sealing position, and a signal is output.

2) The alarm function. In the process of automatic operation, the light bulb can both guarantee the normal work of the system, and can detect sensor control switch.

3.3 The PLC control principle of sealing machine[3,4]

The equivalent circuit diagram of sealing machine PLC as shown in figure 4, outer wiring diagram of PLC is shown in figure 5.

The PLC control principle is: when according to pick up on the outside button SB, drive the first cascade X1 normally open contacts closed, with subsequent T1 by series. (T1 received signal immediately start the countdown, the end of the timing, open, normally closed joint motor (1) off work due to the contact closure, closed on Y1, X1, Y1 forming circuit, relay drive motor 1 works.

When open FR1 by external signal, through the series and subsequent T2. (T2 received signal immediately start the countdown, the end of the timing, open, normally closed joint motor (2) off work due to the contact closure, closed on Y2, X2, Y2 forming circuit, relay drive motor work 2.

When open FR3 by external signal, through series and subsequent T3 and T5. T3 and T5 received signal immediately start the countdown, due to the contact closure, closed through to Y3, X3, Y3 forming circuit, relay drive motor work 2. After the T3 timing, open, normally closed joint motor 2 stop working; After the T4 timing, closed, normally open joint motor 2 began to work again; After the T5 timing, open, normally closed joint motor 2 stop working.

When open FR3 by external signal, through the series and the subsequent T6. T6 received signal immediately start the countdown, due to the contact closure, Y4 closed connect, X3, Y4 forming circuit, relay drivers instructions bulbs work, any action has been prohibit at this time. After the T6 timing, normally closed joint is opened, the indicator bulb stopped working.

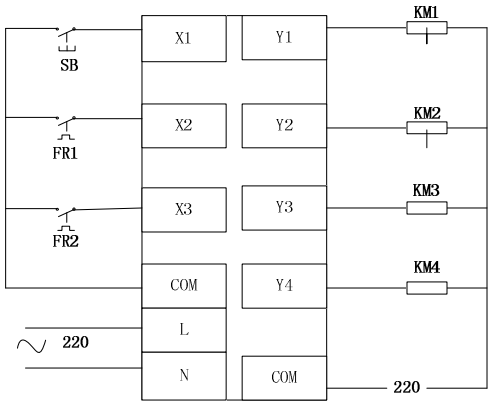

Fig5. PLC external wiring diagram

3.4 PLC introductions[5]

1 LD X1; 2 ANI T1; 3 ANI Y1; 4 OR Y1; 5 OUT Y1; 6 LD X2; 7 ANI T2; 8 ANI Y2; 9 OR Y2; 10 OUT Y2; 11 LD X3; 12 ANI X3; 13 ANI T3; 14 OR Y3; 15 OR T4; 16 OR Y4; 17 ANI T5; 18 ANI Y3; 19 OR T4; 20 OUT Y3; 21 LD X3; 22 ANI X3; 23 OR Y4; 24 ANI T6; 25 ANI Y4; 26 OUT Y4.

Conclusion

In the paper, the cup sealing machine has been studied. On the basis of its working principle and structure of the sealing machine, the sealing machine has been improved design, especially for the cup conveying system. The design make it's from a cup of a seal, sealed into four cups can now be done automatically. The automatic control system has been designed.

The PLC control principle of sealing machine is described in detail, the equivalent circuit and the external wiring diagram have been draw, and the PLC instructions have been written. The cup body movement and control system design of this sealing machine can not only improve the degree of automation, more convenient to use, but also make up for the lack of traditional cup sealing machine design.

Keywords: Optimal Design; Gear modification; Gearbox; Wind turbine

Abstract. This article describes a new mixed transmission system about the wind power gearbox. It is composed of one NGW planetary gear stage and two parallel gear stages. The modeling and optimization analysis of gearbox have been performed using Romax designer software. The load case of gear, gear modification, transmission error and Fast Fourier Transform Harmonics of wind gearbox have been carried out to investigate various performances of gearbox system. Results of the investigation show the maximum load per unit length of gear reduces about 7.2%, Transmission Error of gear reduces 74.3% and Fast Fourier Transform Harmonics decreases 77.4% after gear modification. This kind of design method has a remarkable effect on smooth running. And it provides a new research method for gear box of wind turbine.

Introduction

The worldwide demand for energy is steadily growing. At the same time, this trend is being accompanied by rising greenhouse gas emissions. So we urgently need to correct this course [1]. Wind power is sustainable and clean energy. Compared with conventional energy, generating electricity from the wind does not need fuel; hence there is no risk of a fuel price rise. There are no environmental costs, such as carbon emissions, in the generation process. Wind power has the added advantage that it is widely available worldwide [2].

With the development of modern industry, wind turbine has been taken into account in more and more countries. It is reported that the failure rate of gearbox is very high in the wind turbine [3]. Therefore, it is very important to design a wind gearbox reasonably. And thus many researchers have investigated the wind turbine gearbox transmission system for optimum design of gearbox [4-9].

In the current work, a model of 1.5MW wind gearbox was established with virtual prototype using Romax designer software. The duty cycle, load case of gear, gear modification, transmission error and fundamental frequency harmonic response of wind gearbox have been carried out to investigate various performances of gearbox system. And a lot of parameters of components have been optimized after analyzing and operating in virtual work environment.

Design of the Transmission Scheme

At present, there are many kinds of structures used in gearbox of a wind turbine. In general, multi-stages cylindrical gear transmissions are applied in small and medium-sized power system. While single-stage or multi-stages planetary and cylindrical gear transmissions are used in large power system. Planetary transmission types can be divided into NGW and NW models. In this paper, 1.5 MW wind turbine gearbox is composed of one NGW planetary gear stage and two parallel gear stages. Design requirements of the gearbox are given in table 1. The schematic diagram of wind turbine gearbox is shown in Fig. 1. Table 2 demonstrates the Geometric parameters of gear transmission at all stages after design and calculating according to the design requirements. The 3D model of wind turbine gearbox is shown in Fig. 2 using Romax designer software.

Defining Load Conditions

In current work, Tab. 3 shows the detailed load case.

Tab.3 The detailed load case

Load Case	Input speed（rpm）	Input power（Mw）	Time of duration（hrs）
1st Speed	14.8	1.5	24

Tooth profile optimization of gears

Fig.3 demonstrates that gear mesh deflects due to the elastic deformations of shaft, bearing and gear, and thus the load case in teeth direction is unbalanced. In order to make force balance in teeth width direction, teeth modification should be performed to meet its requirement. The implementation method is through the removal of material to conduct the modification of gear.

Fig. 4 shows load distribution for per unit length of gear. As seen in this figure, gear load in 1st stage presents serious uneven distribution in gear direction. And therefore, it is necessary to conduct gear modification in gear direction. Clicking “Micro Geometry” under “tool menu”, then, double-clicks “Right Flank the Target Form”, and last, clicking “Lead” optimization button, the optimal quantity can be set as “lead slope” in the gear direction. After optimization, the Optimum amount of modification is 5.3 μ m. Fig. 5 shows load distribution after lead modification of gear.

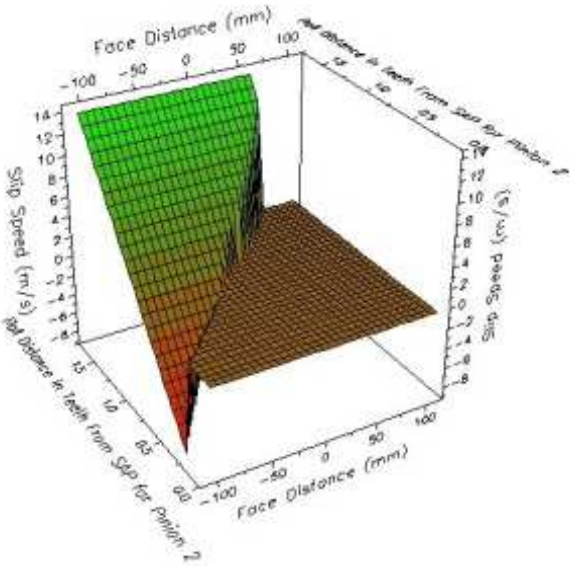

Fig.3 Load surface for gear mesh

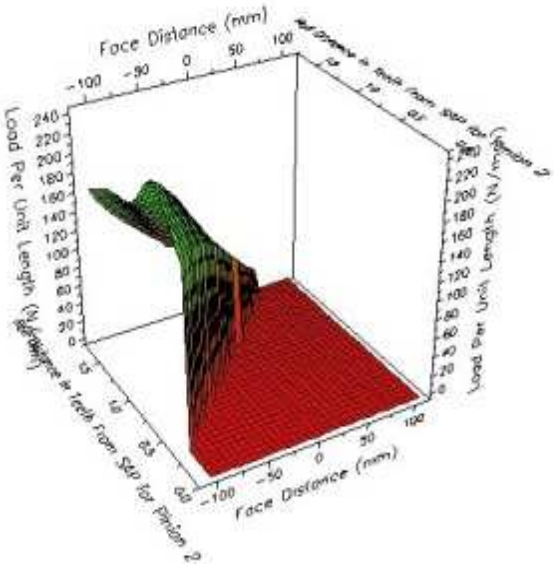

Fig.4 Load distribution for per unit length of gear

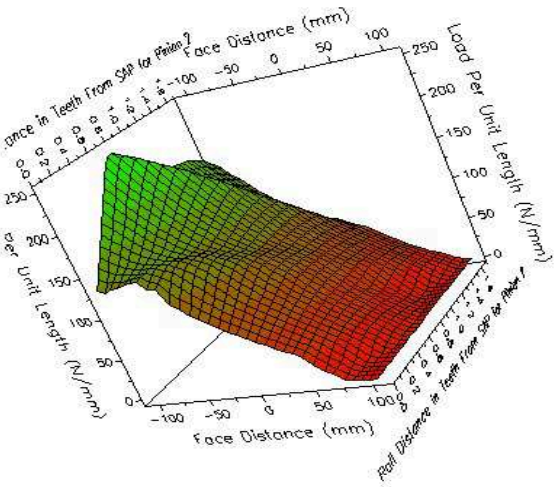

Fig.5 Load distribution after leap modification

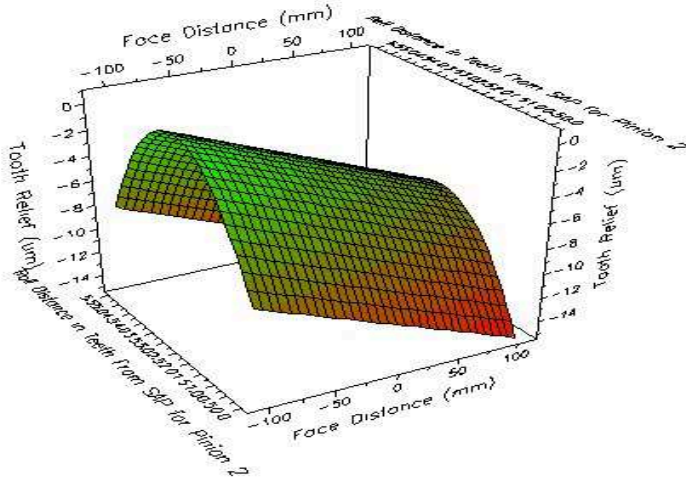

Fig.6 Conjugate mesh relief after gear modification

As seen in Fig.3, mutation of load is very obvious when gear teeth mesh each other. And thus gear involutes modification should be conducted to reduce the mutation of load. After optimization, the Optimum amount of modification is 9μm. Fig. 6 shows Conjugate mesh relief after gear modification. Gear mesh becomes very smoother transition after gear modification.

Comparison analysis of gear before and after optimization

As shown in Fig. 4, the maximum load per unit length of gear is 247 N/mm before gear modification. While the maximum load per unit length of gear is 229 N/mm after gear modification (as seen in Fig. 5). The tooth load decreases about 7.2%. There are load mutations in gear mesh before gear modification. But the gear mesh becomes smooth transition after gear modification.

Gear transmission error curve is an important index reflected the dynamic performance of the gear system. It is an evaluation index of meshing noise. Fig.7 and Fig.8 demonstrate gear transmission errors before and after modification are 0.74 and 0.19, respectively. The gear transmission error reduces approximately 74.3%. The comparison shows that fluctuation of transmission error has not eliminated after gear modification. But error range of gear transmission is significantly reduced.

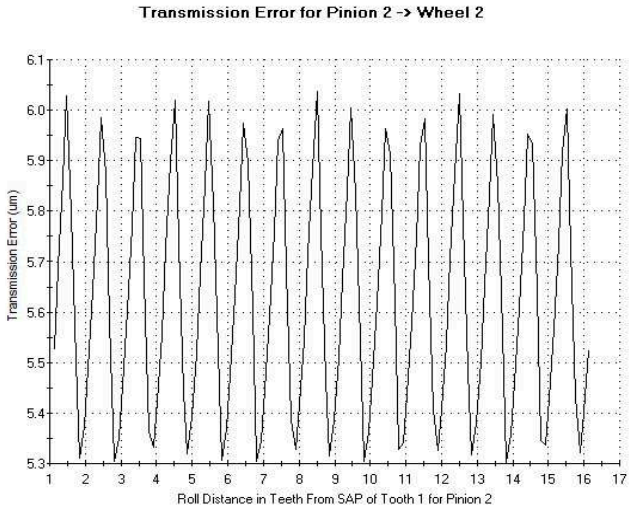

Fig.7 Transmission Errors before gear modification (6.04-5.30=0.74um）

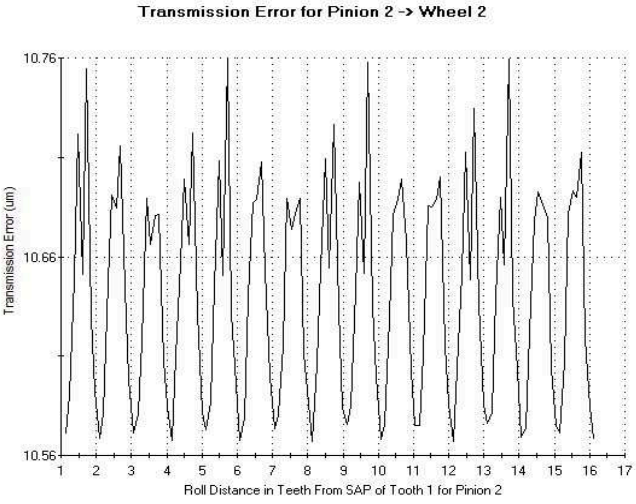

Fig.8 Transmission Error after gear modification（10.76-10.57=0.19um）

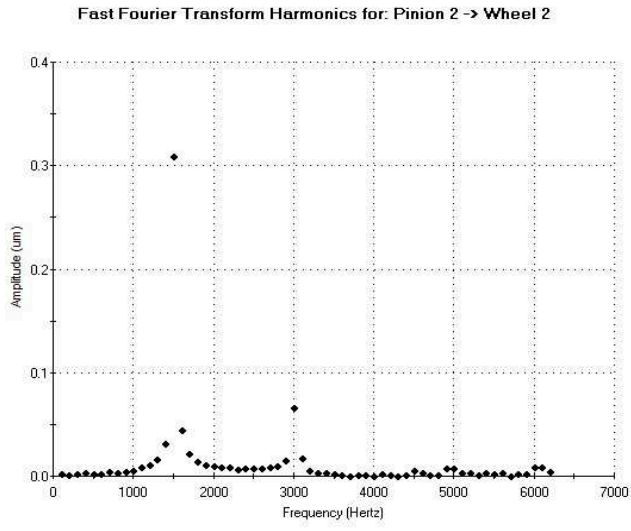

Fig.9 Fast Fourier Transform Harmonics before gear modification

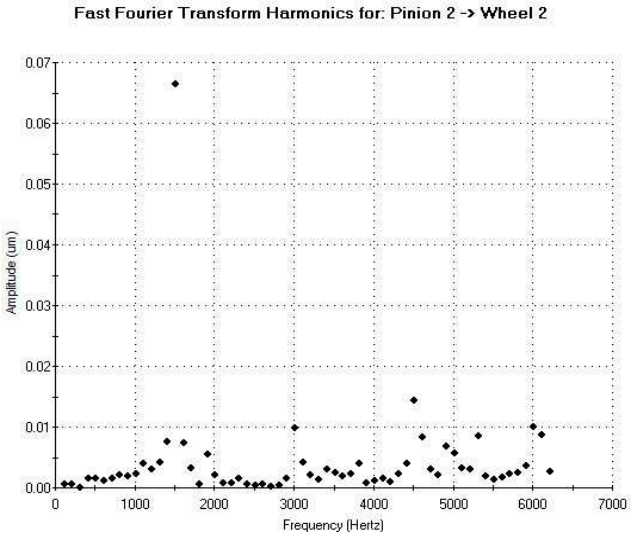

Fig.10 Fast Fourier Transform Harmonics after gear modification

The fast Fourier transform harmonics are present in Fig.9 and Fig.10 before and after gear modification. Through the observation, the Fast Fourier Transform Harmonics (i.e., evaluation index of radiation noise) are 0.31 um and 0.068 um, respectively. It decreases about 78.1%. And thus it plays an important role in improving the bearing capacity of the gear teeth and reducing the noise of gear mesh.

Conclusion

（1）The maximum load per unit length of gear reduces about 7.2% after gear modification. The load mutations in initial gear mesh can be decreased to make it become smooth transition after gear modification.

（2）After gear modification, Transmission Error of gear reduces 74.3%, and Fast Fourier Transform Harmonics decreases 77.4%. And thus it plays an important role in improving the bearing capacity of the gear teeth and reducing the noise of gear mesh.

（3）Romax Designer software can balance the load distribution of tooth surface, improve the quality of gear mesh and reduce the vibration noise of gear. It provides a new research method for gear box of wind turbine.

Keywords: Built-In Electric Spindle; Intermittent Load; Thermal-Structure Coupling; Finite Element

Abstract. Built-in electric spindle has been the core component of machine tool, whose temperature problem is serious. Internal heat source are greatly influenced by load. Based on which has the function of automatic clipping chuck inversion type vertical lathe built-in electric spindle prototype as the research object, using the theory of thermal stress and finite element, established the intermittent load cases hot - structure coupling numerical analysis model of the electric spindle. After overall analyzing electric spindle within the transient temperature field under the action of the intermittent load, the winding temperature changing with time curve is given. On that basis, electric spindle thermal deformation has been carried on the analysis and calculation, gets the shaft extension end axial thermal deformation, provides theoretical basis for the thermal error compensation.

Introduction

With the advancement of CNC machine tools and frequency control technology, electric spindle unit has developed. Spindle performance directly affects the accuracy, stability and range of machining system and applications, thermal characteristics of which has a crucial role during processing. Electric spindle internal heating, thermal conductivity and thermal deformation mechanism doing detailed analysis and research is needed. Determine which method can be effective in calculating the temperature distribution and the spindle thermal deformation under the allowable error range, provides reference for the spindle structural design and thermal error compensation.

For spindle thermal properties of a number of scholars at home and abroad have carried out some research. Bernd Bossmanns and Jay F.Tu [1] established the overall thermal model of electric spindle from the perspective of power distribution for the first time to study the internal heat and cooling spindle forms. Bossmanns and Tu [2] further proposed the overall energy flow model of electric spindle, explaining the main heat sources of spindle system. Guo Jun et al [3] using the finite element method in thermal contact with the temperature field Electric spindle analyzed, and through experiments on the finite element analysis model was checked and verified. XU [4] have got the computational model which has been applied to a large gradient temperature field with combining of the contact thermal resistance model and finite element model. Zhang Minghua [5] conducted steady state, transient temperature field and thermal structure coupled field analysis, and used step-loaded the transient thermal analysis simulates the actual machine tool working one day, got the electric spindle temperature field changes. Holkup et al [6] established a thermal structure coupling model of electric spindle using the finite element method, the thermal structure coupling model can predict the state of the electric spindle under actual working temperature distribution, stiffness and thermal displacement and contacting load bearing through experimental verification. Stein and Tu [7] presented the dynamics digital simulation model of a spindle system from the laws of physics of heat transfer and thermal elasticity, which can be tested as part of the spindle bearing preload system. Jorgensen and Shin [8] analyzed the effect of temperature distribution on the spindle unit dynamics. Sun Min Kim [9] carried out a detailed study on thermal characteristics of

high-speed spindle bearings, got the effects of bearing preload, interference and other changes on the thermal characteristics of the electric spindle. Jenq Shyong Chen et al [10] combined the spindle bearing temperature with thermal displacement by studying the effects of thermal expansion of the spindle bearing friction heat on the spindle, and established a spindle temperature - thermal displacement models.

The calculation of those previous researching is conducted based on continuous operation spindle. The internal heat sources of continuous operation spindle is essentially constant, the temperature curve of which monotonically increasing trend. After reaching a stable temperature, all parts of the spindle thermal deformation also will be stabilized. While the internal heat source of intermittent operation lathe spindle active and passive cooling heat alternates with starting and stopping of the spindle. Internal temperature of electric spindle fluctuations wave ascend. In order to analyze the impact of its internal temperature fluctuations on the thermal deformation of the spindle structure, In this paper, after calculating whole temperature field on the spindle, the spindle thermal deformation under intermittent load conditions has been calculated using the finite element method, providing a theoretical basis for spindle temperature compensation.

Spindle structure and thermal process analysis

The typical structure of built-in spindle is showed in Fig1.

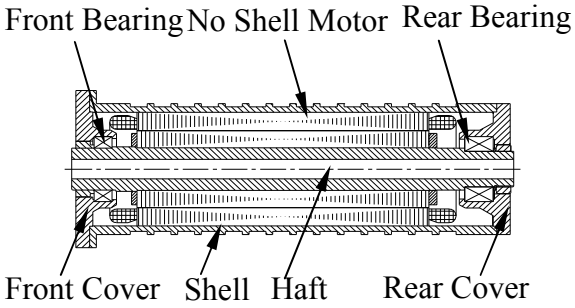

Fig. 1 Typical structure of built-in spindle

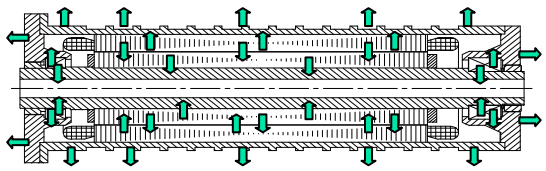

Fig.2 Thermal conduction analysis

For interior permanent magnet synchronous motor spindle systems, the most severe temperature rising of the main place are the stator and front and rear bearings three parts. Part of the heat generated in the stator heat by convection to the front and rear ends of gas passed, and the other housing part with the outside air through the stator heat convection away.There are two ways to heat the rotor: part of the cooling gas generation gap convective heat transfer; transfer to another part of the spindle. There are three ways bearing the heat: the inner part by conduction to the spindle; portion passed through the outer spindle front cover; There is another part of the gas is cooled lubricated away by convection heat transfer; Thus thermal conditions of the bearing is mainly affected the amount of oil flow and cooling gas. In addition, the spindle housing still exist with the surrounding air convection and radiation.

Heat source Analysis under intermittent load cases

Electric spindle move to the upper knife holder after gripping the work piece with power chuck and prepare for cutting. In this process, the rotor accelerated circularly and drive spindle, chuck and work piece from rest. So load of spindle is Traction coursed by Accelerated circular motion and friction of bearing. Rotor and spindle bearings to withstand gravity and preload

Axial spindle accelerates to the desired speed machining, Load only include rolling bearings friction. Screw drive spindle to do feed movement, and spindle start cutting. When cutting, spindle bearing reaction force to withstand the cutting forces, Built-in motors with increased cutting force proportional to the size of copper consumption, In this case the maximum heat for stator winding spindle. Bearing loss increased due to load bearing friction increases.

Finite element method calculations

Lathe spindle can be considered axis of symmetry from the structure and the temperature distribution. So take half spindle profiles to analyze. After simplifying the spindle thermal-structural coupled finite element analysis model was established.

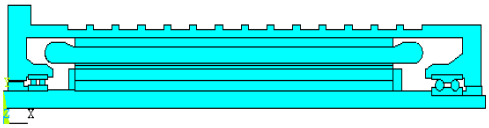

Fig. 3 Aaxial section geometry

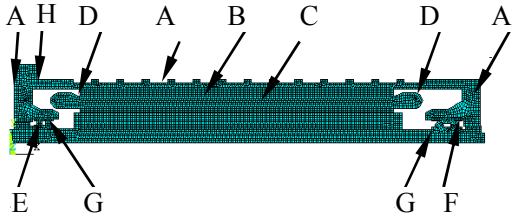

Fig. 4 Meshing and boundary conditions

The actual transfer process is simplified for the finite element model as shown in Figure 4, the winding and core spindle were imposed on copper consumption load B and iron consumption load C, Front and rear bearings apply friction heat generation E and F. Shell and convective heat transfer to the ambient air instead of A, Windings and internal air convection heat transfer to D, Bearings with internal air convection heat transfer to G. Structure boundaries, has been each part of its thermal boundary. Spindle and the base is a fixed location H, Displacement constraints imposed here.

Temperature calculation results shown in Fig. 5, 6.

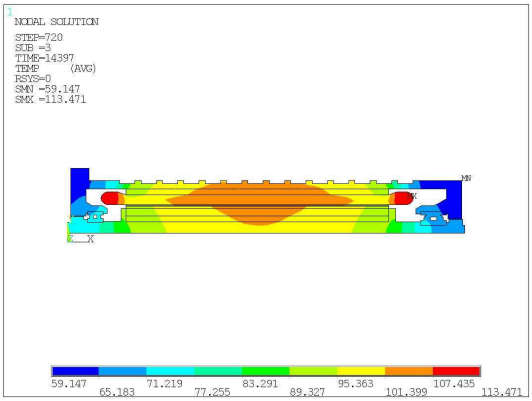

Fig. 5 Internal temperature distribution

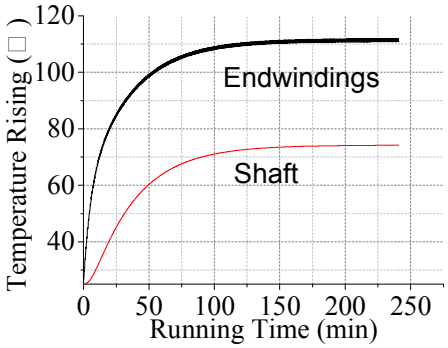

Figure 6 Temperature of winding and shaft end

The highest temperature occurs at where the shaft section end of winding, coursing poor heat transfer conditions of the end windings, External winding complex thermal insulation structure has seriously hindered the end windings. The highest part of the permanent magnet temperature is close to the outer end of the rotor, temperature reaches 110℃.

After running four hours the axial and radial displacement calculation results shown in Fig7, 8.

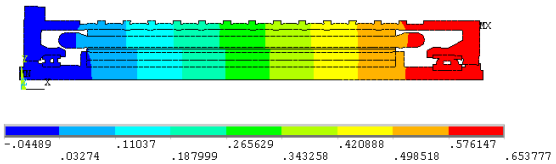

Fig. 7 Axial displacement distribution

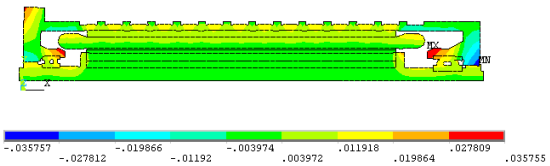

Fig. 8 Radial displacement distribution

Conclusion

Based on which has the function of automatic clipping chuck inversion type vertical lathe built-in electric spindle prototype as the research object, using the theory of thermal stress and finite element, established the intermittent load cases hot - structure coupling numerical analysis model of the electric spindle. After overall analyzing electric spindle within the transient temperature field under the action of the intermittent load, got the following conclusions：

(1) Intermittent load impact seriously on the temperature field spindle, The main factor is the intermittent heat load makes periodic changes in the state over time.

(2) Heat transfer process of active and passive heat alternate. Only the steady-state analysis of the situation when you can not meet the needs of continuous processing multiple parts spindle temperature calculation.

(3) Varying the processing temperature curve should be based compensation to reduce the error between the machine spindle multiple parts.

Keywords: Silicon Microgyroscope; Driving Amplitude; Resonance Frequency; Nonlinear

Abstract. Increasing the driving amplitude could improve the sensitivity of silicon microgyroscope, which is the effective way to enhance the performance of gyroscope. However the large driving amplitude leads to the nonlinear effect. As a result, the resonance frequency is dependent with the driving amplitude, which influences the frequency stability of gyroscope. The equivalent model of driving beam is established, and the stiffness formulas of driving beam are derivated according to the large deflection theory. The linear stiffness of driving beam is 270.1N/m and the nonlinear stiffness is 3.237×108N/m^3, which are 2.7% and 6.4% different from the simulative results. Harmonic balance method can be used to establish the relationship between driving amplitude and resonance frequency. The theoretical analysis results are carried out compared with the simulative analysis results. Also the impact of driving amplitude on resonance frequency is confirmed by experiment test. This paper is significant for improving the frequency stability, and provides a theoretical basis for optimizing the structure of gyroscope.

Introduction

The development of silicon micro-gyroscope offers improvement in cost, size, and ruggedness relative to traditional gyroscope. Thus the silicon micro-gyroscope has a large potential for different types of application, such as navigation, positioning, stabilization, and guidance[1]. Faced to the requirements of high precision applications, the development of high performance silicon microgyroscope is in urgent need. Increasing the driving amplitude is an effective way to improve the performance of gyroscope, which could improve the sensitivity of silicon gyroscope. However the large driving amplitude leads to the nonlinear effect. As a result, the resonance frequency is dependent with the driving amplitude, which influences the frequency stability of gyroscope[2]. The research on frequency stability mainly focused on the temperature characteristic of resonance frequency[3-4]. But the research on impact of driving amplitude on the resonance frequency is rarely reported.

Firstly, the equivalent model of driving beam is established, and the stiffness formulas of driving beam are derivated according to the large deflection theory. Secondly, harmonic balance method is used to establish the relationship between driving amplitude and resonance frequency. Lastly, the impact of driving amplitude on resonance frequency is confirmed by simulation and experiment test.

Theoretical Analysis

Equivalent model of driving beam. The shape of driving beam is U-beam, and a U-beam can be seen as two constrainted cantilevers in series[5]. The schematic of the constrainted cantilever beam is shown in Fig.1(a). A torque M_0 and a force F_x are applied at B, and C is the center of the beam. According to the energy theorem[6], the rotational angle at B is

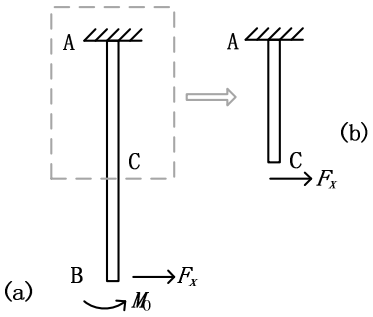
$$\theta_B = \int_0^L \frac{F_x x + M_0}{EI} dx = \frac{F_x L^2/2 + M_0 L}{EI} \tag{1}$$

where E is the Young's modulus, $I=h^3b/12$ is the moment of inertia. L, h, b are the length, width, and thickness of the beam, respectively. According to the boundary condition, $\theta_B=0$. So the displacement and rotational angle at C are

$$\delta_c=\int_{L/2}^{L}\frac{(F_x x+M_0)(x-\frac{L}{2})}{EI}dx=\frac{F_x L^3}{24EI},\quad \theta_c=\int_{L/2}^{L}\frac{F_x x+M_0}{EI}dx=\frac{F_x L^2}{8EI} \tag{2}$$

Meanwhile, according to the moore integration, the displacement and rotational angle of the cantilever, as shown in Fig.1(b), are

$$\delta_{canti}=\int_0^{L/2}\frac{F_x x^2}{EI}dx=\frac{F_x L^3}{24EI},\quad \theta_{canti}=\int_0^{L/2}\frac{F_x x}{EI}dx=\frac{F_x L^2}{8EI} \tag{3}$$



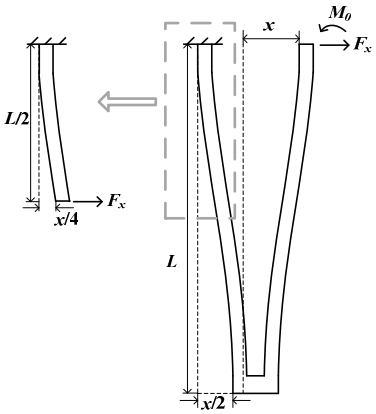


Fig.1 Schematic of constrainted cantilever beam Fig.2 Schematic of equivalent model of driving beam

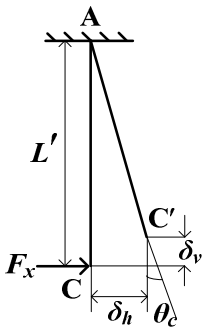
Contrast Equ.(2) and Equ.(3), the rsults are the same. So four series of cantilevers can be used to take the place of a driving beam. The relationship of the displacement and force are shown in Fig.2.

Nonlinear stiffness of driving beam. The cantilever AC(as shown in Fig.1) is deflective largely under the force F_x. The end of cantilever moves from C to C′, as shown in Fig.3. θ_C is the rotational angle, and δ_h, δ_v are the horizontal and vertical displacement, respectively.



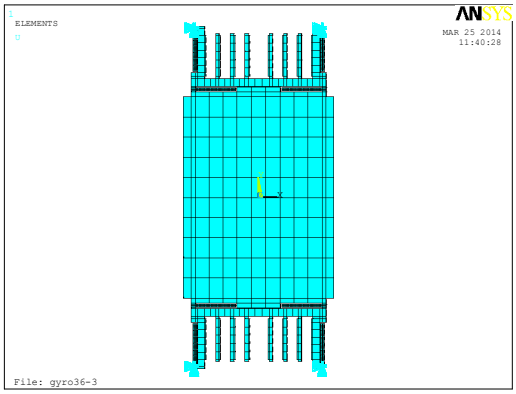


Fig.3 Large deflection of cantilever beam Fig.4 Meshed model of silicon microgyroscope

According to the large deflection theory of beam[7], θ_C, δ_h and δ_v are

$$F(k)-F(k,\phi)=\sqrt{\frac{F_x L'^2}{EI}},\quad \frac{\delta_h}{L'}=1-\sqrt{\frac{4EI}{F_x L'^2}}[E(k)-E(k,\phi)],\quad \frac{\delta_v}{L'}=1-\sqrt{\frac{2EI\sin\theta_b}{F_x L'^2}} \tag{4}$$

where $F(k)=\int_0^{\pi/2}\frac{dt}{\sqrt{1-k^2\sin^2 t}}$, $F(k,\phi)=\int_0^{\phi}\frac{dt}{\sqrt{1-k^2\sin^2 t}}$, $k=\sqrt{\frac{1+\sin\theta_b}{2}}$, $\phi=\arcsin\frac{1}{k\sqrt{2}}$. $F(k)$ and $F(k,\phi)$ are the elliptic integral of the first kind.

$E(k)=\int_0^{\pi/2}\sqrt{1-k^2\sin^2 t}\,dt$, $E(k,\phi)=\int_0^{\phi}\sqrt{1-k^2\sin^2 t}\,dt$. $F(k)$ and $F(k,\phi)$ are the elliptic integral of the second kind.

Because the transcendentality of Equ.(4), the iterative method is used to obtain the relationship between $F_x L'^2/EI$ and δ_h/L'. The specific precess is: 1. Set initial value to θ_c($0°<\theta_c<90°$); 2. Solve k; 3. Solve ϕ; 4. Solve $F(k)$ and $F(k,\phi)$; 5. Solve $F_x L'^2/EI$.

According to the solving program of elliptic integral[8], the program of obtaining the relationship between $F_x L'^2/EI$ and δ_h/L' is achieving by C++. One hundred sets of $F_x L'^2/EI$ and δ_h/L' are outputted by the program. Then the curve fitting is achieving by matlab.

$$\frac{F_x L'^2}{EI} = 3\frac{\delta_h}{L'} + 3.15\left(\frac{\delta_h}{L'}\right)^3 \tag{5}$$

Equ.(5) can be written as $F_x = k_{c1}\delta_h + k_{c3}\delta_h^3$, $k_{c1} = 3EI/L^3$ is the linear stiffness of the cantilever, $k_{c3} = 3.15EI/L'$ is the nonlinear stiffness. According to Fig.2, $\delta_h = x/4$, $L' = L/2$.

$$F_x = \frac{6EI}{L^3}x + \frac{1.575EI}{L^5}x^3 \tag{6}$$

where $k_{u1} = 6EI/L^3$ is the linear stiffness of the driving beam, $k_{u3} = 1.575EI/L^5$ is the nonlinear stiffness.

Impact of driving beam on resonance frequency. The motion equation of the mass under the harmonic driving force is

$$M\ddot{x} + C\dot{x} + K_1 x + K_3 x^3 = F_x \sin\omega t \tag{7}$$

where C is damping coefficient, ω is the frequency of driving, and K_1=4k_{u1}, K_3=4k_{u3}. Assuming the solution of Equ.(7) is $x(t) = X_m \sin(\omega t - \varphi)$. According to the harmonic balance method[9],

$$X_m = \frac{F_x / M}{\sqrt{\left(\omega_n^2 - \omega^2 + \frac{3}{4}\frac{K_3}{M}X_m^2\right)^2 + \left(\frac{C\omega_n}{M}\right)^2}} \tag{8}$$

So the resonance frequency when the amplitude is the largest is

$$\omega^2 = \omega_n^2\left(1 + \frac{3}{4}\frac{K_3}{K_1}X_m^2\right) \tag{9}$$

Taylor expansion can be used to obtain the approximate relationship between the amplitude and resonance frequency.

$$\omega \approx \omega_n\left(1 + \frac{3}{8}\frac{K_3}{K_1}X_m^2\right) \tag{10}$$

The resonance frequency shifts with the change in driving amplitude, and the shift value is approximate linear with the square of the amplitude. As the amplitude increases, the effect of nonlinearity on the resonant frequency can not be ignored.

Simulative Analysis

ANSYS is used to analyse the motion of the gyroscope. The meshed modal of the gyroscope is shown in Fig.4. All the degrees of freedom on the ends of driving beams are constrained. The different displacements along X axis are applied on the mass. And the displacements along Y axis and Z axis are set zero. The large deformation option is opened, and the reaction forces of one driving beam are extracted with FSUM command. The simulative result is shown in Fig.4. The simulative values of stiffness of the driving beam are obtained by matlab fitting. Both the theoretical values and the simulative values are listed in Tab.1

Tab.1 Theoretical and simulative results of stiffness of driving beam

Stiffness	Theoretical Value	Simulative Value	Error
k_{u1}(N/m)	270.1	263.1	2.7%
k_{u3}(N/m^3)	3.237×10^8	3.458×10^8	6.4%

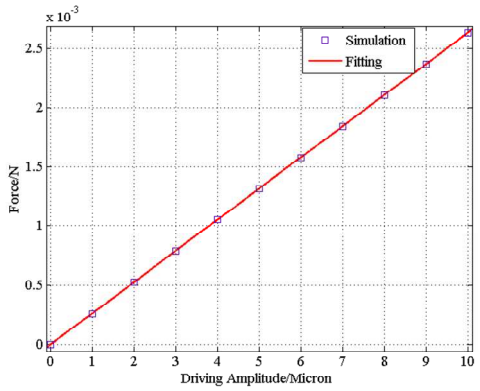

Fig.5 Simulative results of stiffness of driving beam

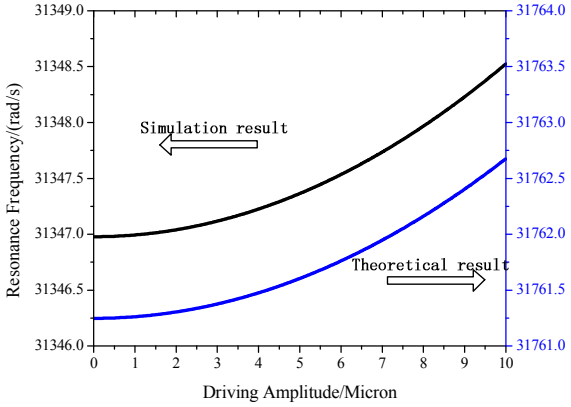

Fig.6 Theoretical and simulative results of impact of driving amplitude on resonance frequency

According to Equ.(10), the simulative result of the impact of driving amplitude on resonance frequency can be obtained, as shown in Fig.6. The theoretical result is validated by the simulation.

Experimental Analysis

The gyroscope is driven in open-loop mode. The driving DC bias voltage V_d is 15V, and set the amplitudes of driving AC voltage V_a are 20mV, 40mV and 60mV respectively. The signal source is used to sweep the frequency of V_a. Meanwhile, the driving-sensing voltage is recorded, as shown in Fig.7.

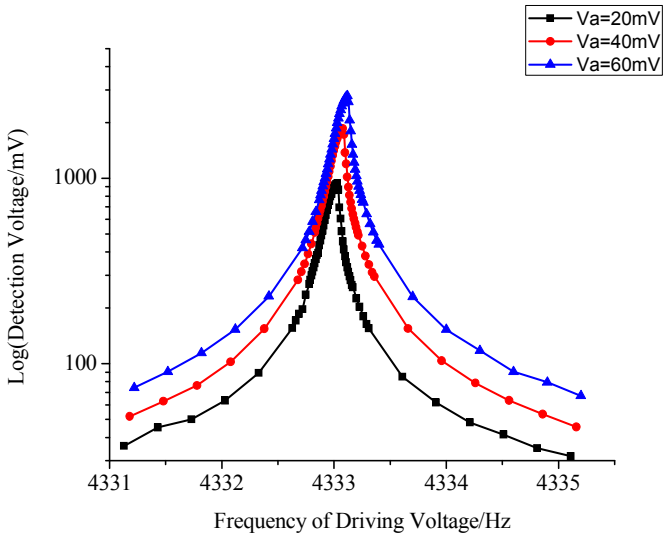

Fig.7 Amplitude-frequency characteristics of driving detection signal with different driving AC voltage

As seen in Fig.7, at the same frequency, the driving-sensing voltage increases when V_a is increased. The resonance frequencies of gyroscope increases with the increase of driving amplitude. The impact of driving amplitude on the resonance frequency is validated by the experiment.

Conclusion

The equivalent model of driving beam is established in this paper, and the stiffness formulas of driving beam are derivated according to the large deflection theory. The linear stiffness of driving beam is 270.1N/m and the nonlinear stiffness is $3.237\times108\text{N/m}^3$, which are 2.7% and 6.4% different from the simulative results. The theoretical formulas are verified by the simulation. Harmonic balance method is used to establish the relationship between driving amplitude and resonance frequency. The resonance frequency shifts with the change in driving amplitude, and the shift value

is approximate linear with the square of the amplitude. The theoretical and simulative reults of the impact of driving amplitude on the resonance frequency are given, and the impact is validated by the experiment. This paper is great significance for improving the frequency stability of the gyroscope, and can provide practical guidance and theoretical basis for design and optimization of the gyroscope.

Keywords: Credit Evaluation; Vague Set; Factor Analysis; Structural Equation Model

Abstract. The paper aims to develop the credit evaluation and verification model in equipment manufacture industry. The study defines the vague set of linguistic variable firstly. Then the calculation rules are defined with the vague set. The research uses the expert subjective judgment to build the initial evaluation model. And the relevant 128 data items are collected by survey. These items are used to make factor analysis to test the structure of the evaluation system and build the initial SEM. The result of SEM shows the possible modification. Finally, the empirical research is given to verify the developed approach.

1. Introduction

The equipment manufacture industry is the important part of national economy. In traditional, most of the Chinese equipment enterprises are state owned. And most of the equipment R&D projects are developed by investment of state. The target customers are often allocated by the authority sectors in advance. So the assets of project should be managed by State property management sectors. And the profit of the project should belong to the state. The Relationships among the enterprise, the management sector and the target customers have not the simple link of business transactions but the co-operational partners shared with common interests. However, the enterprises may have their own position and interest though it is state owned. The enterprises don't want to the target customers or state sectors know the details about their technology level, finance status and management method for their own benefit. In fact, it is difficult to the target customers to get hold of the real status of the enterprise [1]. The past research shows that many manufacture resource was wasted [2]. And the authority sectors lack detection methods to evaluation the equipment enterprises [3].

To analyze the real status of the manufacture industry for the management sectors, it is required to establish the credit evaluation system of the enterprises. The enterprise credit is used to describe the compliance capabilities and financial level. At first, the credit level mainly refers to the commercial credit. Then it became an important indictor to all of the investors. In manufacture industry, the credit level describes the debt affordability, service level and compliance capability of the enterprise.

The past researches often build the evaluation system with subjective method or objective method. Tian Fei believe each of methods presents advantages and disadvantages [4]. So he suggests that the different method should be applied to make a balance. The research builds the initial evaluation model with the fuzzy evaluation method firstly. This model is mainly developed by the experts' expertise and judgment. The evaluation index system and procedure are two core factors of credit evaluation standardization. Then the research verifies the system with the structural equation model. The structural equation model may suggest the Modification of the evaluation system [6]. Finally, the empirical research suggests it is an efficient method.

2. Basic Definitions

Definition 1: Set U is the universe of discourse, the element x belong to U, the vague set in U is a couple membership function $t_A(x)$, $f_A(x)$. The membership function meet the following requirements[5]:

1) $t_A(x) \to [0,1], f_A(x) \to [0,1]$; (1)

2) $0 \le t_A(x) + f_A(x) \le 1$ (2)

The $t_A(x)$ is called true membership function, the $f_A(x)$ is called false membership function, the $\pi_A(x) = 1 - t_A(x) - f_A(x)$ means the hesitate level.

Definition 2:Let Comparison linguistic variable P={xj}, xj=[ti, 1-fi], j is odd number and j>1, i=1,2,…,j. the Comparison linguistic variable follow the below rule:

1) If i≥k, then ti≥tk , it means that ti gets the higher degree of membership on xj than tk;
2) The comparison linguistic variable is transformed into triangular fuzzy number, and the interval number is defined as λ-cut sets of triangular fuzzy number.
3) Abstention part π_{ij} of linguistic variable rise from both ends to midrange, but it is zero in the midpoint. i.e., the interval number of 7 level linguistic variables is given by Table I(λ=0.5).
4) Set U is the universe of discourse, the linguistic variable x display a couple membership function t_{ij} , f_{ij} , let $a_{ij} = [t_{ij}, 1 - f_{ij}]$, $t_{ij} \to [0,1]$, $f_{ij} \to [0,1]$, $0 \le t_{ij} + f_{ij} \le 1$,then the vague set in U, the vague set of 7 level comparison linguistic variables is defined as Table II.
5) Abstention part π_{ij} of linguistic variable rise from both ends to midrange, but it is zero in the midpoint. Miller (1956) believes the human beings have a limited capacity to work simultaneously with more than nine categories [6]. So the most common used linguistic variable is defined no more than 9 levels.

3. Credit Evaluation and Verification

The research builds the initial credit evaluation model with fuzzy method. The mainly steps as below:

Step 1: Get the linguistic variable of evaluation index by the classic expert judgment;

Step 2: Transform the linguistic variable to the vague based on the former definition;

Step 3: Calculate fuzzy weight of evaluation index based on the complementary judgment matrix and it's calculate rules;

Step 4: Get the α cut set of the fuzzy weight set, and take it as the initial path coefficient of the credit evaluation model.

Then the study investigates relevant data of evaluation factors and makes the factor analysis. The factor analysis is used to test the structure of evaluation system. An initial structural equation model (SEM) was built based on the result of factor analysis. The structural equation model is used to explore the real relationship between the different variables. The SEM builds a $p \times p$ sample covariance matrix with the P observations of N samples to test the relationship between the different variables.The model can be solved with the below equation set[7]:

$$X = \Lambda_x \xi + \delta \quad (3)$$

$$y = \Lambda_y \eta + \varepsilon \quad (4)$$

$$\eta = B\eta + \Gamma\zeta + \zeta \quad (5)$$

The B and Γ are path coefficients, the B suggest the relationship between the endogenous latent variable, and Γ is the influence of exogenous latent variable to the endogenous latent variable. ζ is the error item. The test indictor may give the possible modification of the evaluation model.

4. Empirical Research

The authorities take moves to boost the national economy with a revitalization plan in 2008 global financial crisis. The authority sectors decided some equipment R&D projects to response to the crisis. The management sector tried to build evaluation system to analyze the status of these enterprises which take part in the plan. The credit evaluation and verification is the important part of this system. The authority sector wants to know the status of the compliance capabilities, product quality, after-sale services and financial level through the study.

They studied a random group of 31 enterprises from these equipment enterprises which take part in revitalization plan. The 25 experts give their personal evaluation based the way shown in basic definitions. The group calculates the final result with the method defined in former paragraph. The result of weight is in the table 1 and fig 2.

Table 1 Weight assigned by Experts

Index	*Fuzzy Weight*	*Classic Weight*
Customer Satisfaction	(0.44, 0.61, 0.79)	0.615
Qualification	(0.56, 0.74, 0.88)	0.733
Past Production Level	(0.73, 0.93, 1.00)	0.901

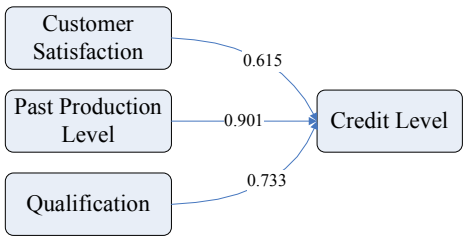

Fig. 2. Credit level Evaluation Model

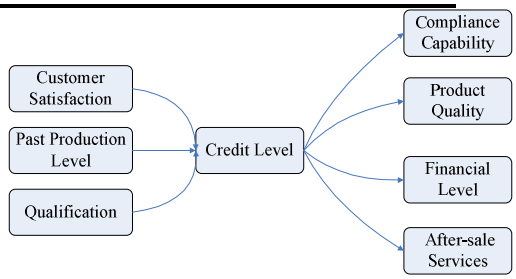

Fig. 3. Initial Credit level Model

Then the research investigated the data of 128 items. These items involved with past compliance capabilities, quality, customer service and financial level. And the study group developed an analysis model for credit level with factor analysis. The Kaiser-Meyer-Olkin，KMO value(0.805) suggests is fit for factor analysis[8][9]. The result of factor analysis show the 128 items belong to four factors. All Cronbach's Alpha of four factors are bigger than 0.90, it means acceptable reliability [10]. The research names the four factors as compliance capability, product quality, after-sale services and financial level factor. The initial model is given in fig 3.

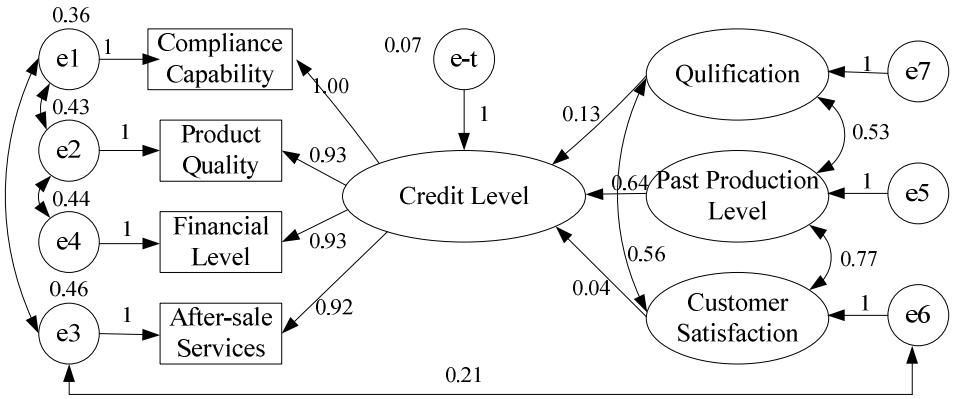

Fig. 4. Modification Credit Evaluation System

The study verifies the initial model with structural equation model. The structural equation model result suggests the possible modification of the evaluation system. The path coefficient is in the fig 4.

5.Conclusion

This paper investigates equipment enterprise credit evaluation problems with fuzzy expert judgment and survey information. We first define the vague set of linguistic variable and its calculation rules. Then the research makes the factor analysis to build the initial evaluation model. With the result of factor analysis, a structural equation model was built to test the path coefficients. The result of the SEM shows the possible modification. Finally, the empirical research is given to verify the developed approach.

Key words: coil transporters; running mechanism; lifting device; guide pulley

Abstract. Coil transporters are widely used in rolling production line to transport coils among different positions. Aiming at the inaccurate parking space, low production efficiency, high requirement of working accuracy, inconveniency in repair and other problems during the working process, the running mechanism and lifting gear of the coil transporter have been improved, And the author analyze the structure of the improved body by FEA. The results of the analysis of car body show that strength and stiffness meet the requirements. The general property of the improved coil transporter has been, in a good condition, effectively bettered. It can meet the production requirement and enhance the economic benefits.

Introduction

The development of steel rolling production depends not only on the increasing speed of the main equipment of steel rolling and shortened rolling cycle, but also largely on the continuous improvement and enhancement of the auxiliary equipment of steel rolling production. As an important auxiliary equipment of steel rolling, coil transporter whose performance directly affects the quality of the coil and the production efficiency of the unit is widely used in steel rolling production line and used for different location between the transmission coil. Therefore, improving the structure of the coil transporter is particularly important. It aims at increasing the operation efficiency of the production, reducing the maintenance cost, and improving the iron and steel enterprise economic benefits.

The current situation of traditional coil transporter

Traditional coil transporter is composed by walking track, running mechanism, lifting gear, hydraulic system and the energy chain. Walking track is made by two stell tracks which is attached at the bottom of the fixed platform. It is also the support rails of the framework's horizontal motion. Framework is composed by lifting frame, car body, wheel assembly, and lifting hydraulic cylinder. lifting frame is welding structure with 4 guide pillars. Car body is also a welding structure equipped with 4 guide sleeve. Lifting hydraulic cylinder installed is in the central part of the framework. Four wheels are installed on the car body convenient for the car to walk on the orbit.

Running mechanism can promote the coil car do horizontal motion in orbit working with ac motor via a reducer, coupling two wheels. The distance is measured by the proximity switch trip. Due to the low power of the torque in the coil transporter and the walking system, the existing steel coil transporter is driven by concentrated form[1]. The travel mechanism of steel coil transporter is shown in figure 1.

Lifting device is driven by hydraulic cylinder. When hydraulic cylinder drives the lifting body up and down, 4 guide sleeve and 4 guide posts make relative movement in the vertical direction. In this way, the movement not only plays a guiding role, also controls the accuracy of vertical movement. The cooperation of guide sleeves and guide columns adopts automatic lubrication by concentrated dry oil. At the same time, movement distance is measured by the proximity switch. The lifting device of the steel coil transporter is shown in figure 1.

Fig. 1 The schematic diagram of the original running mechanism and lifting device

Common problems and their causes in the coil transporter working process

Common problems and their reasons in the running mechanism working process

Problems often appear in the working process, like the wheel sliping, inaccurate parking position, and the strong impact when workers start and stop the machines. The reasons are: the traditional coil transporters are driven by the wheels, and the wheels are driven by motor and the gear reducer. Transporters walk and brake relying on the friction between the wheel and rail car. After a period of working, the wheels wear, and the surface become smooth, which lead to the reduction of the friction. Because of the relative sliding between rails and wheels in the braking process, wheels will slip on the surface of the rails, resulting in the inaccurate parking positions[2]. In addition, the transporters that are driven by a motor are easy to get strong impact when workers start and stop them. The traditional steel coil transporters are parked by the proximity switch to control positioning, so after a period of time, due to the deformation of the guide rails, the proximity switch can't be connected with signal part, which also leads to the same problem.

Common problems and their causes in the lifting device working process

The lifting device often have serious problems, like serious friction in the guide structure, high precision in manufacturing, inconvenient repair, high processing cost, and low productivity. The reasons are: The lifting frame driven by the hydraulic cylinder moves up and down, 4 guide sleeve and 4 guide columns relatively moves in the vertical direction[3], therefore the high manufacturing precision and the rigidity of the guide columns and guide sleeves are highly required. The guide columns will shake when rising. Imprecise-produced guide columns and guide sleeves or bad surface lubrication in the work process can cause serious friction loss on contact surface, can consume extra energy, and can influence the efficiency of rolling production. And, the guide columns and the guide sleeves need larger space. Once they are in trouble, it is not convenient to detect and repair. If bigger problems appear, artifacts are needed, which greatly increases the cost and reduces economic benefits.

The improvement of the structure and its effects

The improvement of the running mechanism

The original running mechanism is connected with the wheel by a motor, a reducer and a coupler, driving wheels and the car. After the improvement, the gear driven by the hydraulic motors, through the meshing of the gear and the walking track below the fixed rack, the gear shaft and the body rotate which can drive the carriage walk. In this process, wheels are passively driven. The accuracy of gear shaft position can make sure the right position of the transporters. At the same time, the gear is connected with the encoder, which means that parking position is controlled by the encoder, and that the car can be parked in the right position for a long time only after one adjustment in the process of operation. Precision is guaranteed. At the same time, the running mechanism is driven by a hydraulic motor, without any impact when working. The improved steel roll running mechanism of transporters is shown in figure 2.

3-Guide wheel 4-Steering column
5-Hydraulic cylinder 6-Car body

a. Running mechanism b. Lifting device

Fig 2 The schematic diagram of the improved running mechanism and lifting device

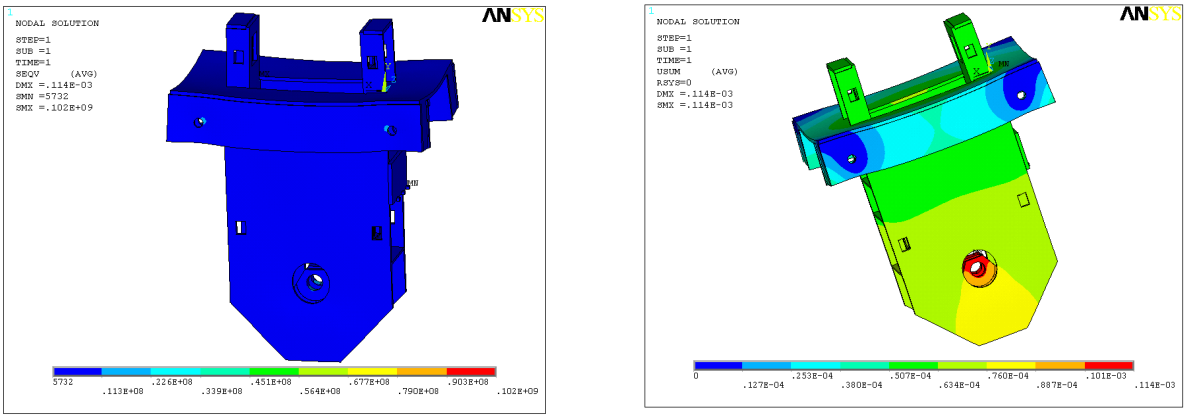
The improvement of the lifting device

The original lifting device is guided by guide posts and the guide sleeve, improved device is only guided by the guide wheel. They have simpler structure, low requirement for machining precision. The lifting frame works more stably, reduces the shaking, is easily repaired , and is conveniently removed and replaced, which save equipment maintenance time and improve the car online operation rate. At the same time, the proximity switch detecting the lifting frame position is changed to the encoder that can more accurately position. After the improvement, the steel coil lifting device of transporters is shown in figure 2.

The analysis of the coil transporter

After the improvement of the coil transporters, the running mechanism and the lifting device structure has changed greatly, leading to the structure of the car body' changes. When working, the car body bears the steel coils, lifting frame, the saddle. So it is necessary to analyze the strength of the structure of car body. In this paper, the model was established by Solid-Works software. The author simplifies the model, deleting the features which have no or few effects on the practical issues, such as some smaller hole thread structure. This way can reduce the number of features of model[4]. The Solid-Works model is imported into ANSYS software. The car body is analyzed and calculated by ANSYS software, so as to obtain the stress and deformation data when the car body bears the steel coils, and to test whether they meet the requirements.

The whole car body is made by Q235B carbon steel, whose elastic modulus is 210 gpa, poisson ratio is 0.3, the density of 7850 kg/m3, and the yield limit of 235 MPa[5]. The coil weighs 25 tons. The car body, the lifting parts, the saddle totally weighs 6000 kg. Using solid45 hexahedron unit in the ANSYS to proceed the free meshing the model.Impose all constraints on the surface of the four cylindrical holes' inner surface of the wheels in the car body. In the working process, the total weight of the steel coil, the transporter, the lifting parts, and the saddle loads on the lower surface of the hydraulic cylinder in the transporter. Through finite element analysis, the equivalent stress distribution chart is shown in picture 3. According to the picture, welded stress value is bigger on the position of the holes in the transporter and on the connected position of the horizontal plates and vertical plates, the maximum stress being 102 MPa. As we can see, the maximum stress of car-body is less than the material yield limit in the process of lifting steel coil, satisfying the requirement of static strength. Displacement nephogram is shown in picture 3. The picture shows that the maximal displacement deformation of the transporter occurs connected part between the body and the lift hydraulic cylinder, the maximum being 0.114 mm. The tiny deformation has no effect on the normal work of the steel coil transporter. Stiffness also meets the requirements.



a. Equivalent stress distribution nephogram b. Displacement nephogram

Fig 3 Equivalent stress distribution nephogram and displacement nephogram of the car body

Conclusion

1) The improved steel coil transporter, proved by simulation use, can completely meet the needs of production. Compared with the old machine, the improved structure is simpler, has no impact on the brake, runs more smoothly, positions more accurately, maintain more conveniently. It can really achieve smoothness, accuracy, high efficiency, energy saving. The rate of the equipment failure is greatly reduced, and maintenance is easier and more convenient.

2) Through the study of the finite element analysis of car body, the results show that the improved structure has sufficient strength and rigidity, and can satisfy the demands for the normal work of the steel coil transporter.

Keywords: Ruled Grating; Edge Radius; Finite Element

Abstract. Diffraction grating is a kind of very sophisticated optical element, It is usually used diamond ruled grating. Edge radius is one of the important parameters of diamond ruled grating, the effect of the edge radius to diffraction efficiency and ruled depth is analyzed by the theoretical calculation and finite element analysis in this paper. Get the influence law of diffraction efficiency, ruled depth and the ruling force, which has provided the theory basis for correctly precision edge radius.

Introduction

Along with the rapid development of spectral instruments and laser fusion technology, ruled grating has been more and more widely used in the economic, scientific research and the military field.The same attention to the development of grating manufacturing in China. The diffraction grating as the precision of the optical element[1].Among them, the sort is the use of diamond scribing iron grating in coated metal film layer on the base of extrusion, the polishing process. So to get high quality ruled grating, first must have a very sharp, accurate angle, excellent roughness, abrasive resistance is discussed [2].

The ruled grating graver is one of the ultra-precision diamond tool. No matter how fine production, can not be made into a sharp geometry line in production [3]. Within the cross section perpendicular to the main blade, The main cutting edge is actually a curve. Commonly used arc instead of the main blade edge shape. The circular arc of the edge radius to express the degree of the cutting tool edge sharp in order to adapt to a variety of processing requirements, edge radius range from 20nm-l μ m. In this paper, the study on edge radius on the grating diffraction efficiency, ruled depth and the ruling force [4].

The Influence of the grating diffraction efficiency

Diffraction efficiency of grating is one of the basic features, when choosing the cutting edge radius, the first thing to consider about the influence of diffraction efficiency.Grating trough theoretical contour shape is a triangle, as shown in figure 1 [5].

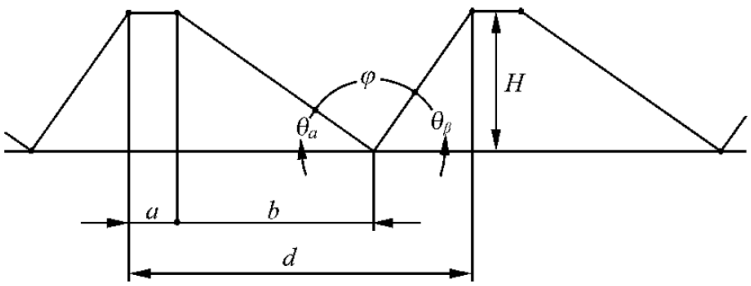

Fig.1. The theory outline of grating trough

In the figure 1, θ_a stands for blazed angle; θ_β stands for other blazed angle; φ stands for grooved angle; *a* stands for the zero-order surface width; *b* stands for transverse dimensions of effective blazed surface; *d* stands for grating constant ; *h* stands for the depth of the trough.

As a result of the existence of the edge radius, shining side with the shining side of intersect with a circular arc, this will reduce the effective glare grating surface transverse size *b*, thereby reduce the diffraction efficiency of grating.

We already know that the diffraction efficiency as follows :

$$\eta = a^2 \sin c^2[m\frac{a}{b}] + b^2 \sin c^2\{b[\frac{m}{d} - \xi]\} - 2ab \sin c[m\frac{a}{b}] \sin c\{b[\frac{m}{d} - \xi]\} \cos \pi \left[m\frac{a}{b} \right] \tag{1}$$

In the type, $\xi = \frac{1}{\lambda}[\cos\alpha + \cos\beta]\tan\theta_a$, *a* stands for angle of incidence, β stands for diffraction angle.

Don't consider the zero-order surface *a*=0, we can find:

$$\eta = b^2 \sin c^2 \left\{ b\left[\frac{m}{d} - \xi \right] \right\} \tag{2}$$

Considering edge radius, $b = \left[\frac{H}{\sin\theta_a} - r \right] \cos\theta_a$, In the type, we can find:

$$\eta_e = \left\{ \left[\frac{h}{\sin\theta_a} - r \right] \cos\theta_a \right\}^2 \sin c^2 \left\{ \left[\frac{h}{\sin\theta_a} \right] - r \right\} \cos\theta_a \left[\frac{m}{d} - \xi \right] \tag{3}$$

With the theory of diffraction efficiency ratio, we can find:

$$\frac{\eta_e}{\eta} \approx \left\{ \frac{\frac{h}{\sin\theta_a} - r}{\frac{h}{\sin\theta_a}} \right\}^2 = \left[1 - \frac{\sin\theta_a}{h} \cdot r \right] \tag{4}$$

Calculated by the formula 4,we find the table 1.

Table 1 Diffraction efficiency of different edge radius

Edge radius	*r* = 0. 1μm	*r* = 0. 2μm	*r* = 0. 5μm	*r*= 1μm
Efficiency ratio	96. 496%	93. 055%	83. 105%	67. 773%

The Influence of ruled depth

Mechanical characterization of grating, the precise characterization of ruled depth, guarantee the design outline of the correct contact, avoid excessive ruled[6].Actual ruled process, the use of diamond characterization of grating graver is usually asymmetric grating graver, so the center of the circular arc edge is not in circular arc edge and aluminum membrane directly above the contact point, the △X and △Y is a function of the edge radius.So when making the graver, position error compensation should be made for grating graver position error compensation formula can be made of geometric relationships as follows:

$$\Delta X = \sqrt{2} \sin\left[\theta_a - 45°\right] r \tag{5}$$

$$\Delta Y = \left\{ \sqrt{2} \cos\left[\theta_a - 45°\right] - 1 \right\} r \tag{6}$$

So we can get actual indented depth of grating graver ,

$$h = h_0 - \Delta Y = h_0 - \left\{ \sqrt{2} \cos\left[\theta_a - 45°\right] - 1 \right\} r \tag{7}$$

In this type, h_0 is the theory of indented depth. From what has been discussed above. With the increase of cutting edge radius, indented depth increased.

The Influence of ruling force

Despite its grating in the process of mechanical characterization can be divided into three: forward force, crossrange force, press force.Forward force along the grating graver ruled direction, provide the grating graver forward momentum; Lateral force vertical grating graver curve direction; Vertical grating surface under press force, control the indented depth [7].

By using the finite element software Deform-3d simulation of grating mechanical process, despite its research in the process of mechanical characterization.

Table 2 The Influence of the three force

Radius force /N	0.1μm	0.5μm	1.0μm
Forward force	0. 00489	0. 00506	0. 00512
Crossrange force	0. 0558	0. 0529	0. 052
Press force	0. 213	0. 221	0. 233

Deform is the Battelle colom bus laboratory development of large general finite element analysis software, mainly used for the analysis of all kinds of metal forming and its associated forming process and heat treatment process[8].By Deform -3d simulation of the process in which arc grating graver ruled diffraction grating, to reduce the number of grid, reduce the calculation time, the selection of aluminum film covers an area of 200μm x 120μm, the thickness of 3.5μm.

In the process of ruled, aluminium film plastic and elastic deformation occurs, thus it set as elastic-plastic body;For diamond tool material, its strength and hardness is much higher than the aluminum membrane materials, in the process of characterization of strain is very small, so it is set to the rigid body.Featured in the simulation process, the aluminum membrane fixed at the bottom, before and after the face said constraints;Indented depth under different cutting edge radius is selected according to table 2, the ruled rate is 50 mm/s[9].

Using Deform -3d finite element calculation, the ruling force in the process of characterization of measurement, measurement results as shown in figure 2.

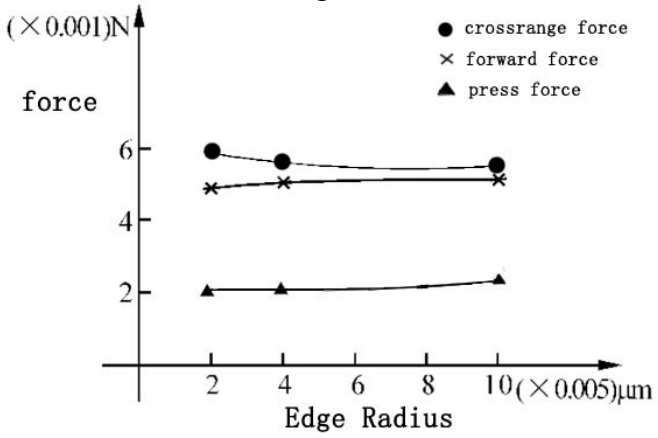

Fig.2. The change curve of ruling force

Respectively to make progress, crossrange force, press force change with arc nicking tool edge radius curve, as shown in figure 2.You can see from figure 2 progress, the pressure increases with cutting edge radius and bigger, this is because the knives on the direction of progress, under pressure to split of aluminium film, blade, cutting tool dull, need to force too big.Crossrange force increases with cutting edge radius and smaller, because the crossrange force main effect is to ironing grating groove surface polishing, increases as the edge radius, ironing area decreases, and thus less crossrange force also.

Conclusion

Ruled in the grating edge radius increases, shining surface transverse effective grating size b decreases, and the diffraction efficiency is lower.In the process of mechanical characterization of grating, affect the ruled of knife edge radius location and characterization of depth, and according to the position error compensation formula, ruled cutter location compensation, determine the actual

ruled depth, can avoid the occurrence of excessive ruled.Finite element simulation results show that edge radius, ruled knife is sharp, progress and smaller pressure, reduce the ruled consumed power;Crossrange force become larger, the enhancement of the grating groove surface polishing effect, improve the quality of the grating groove face.

Keywords: stress characterization; MEMS; mechanical analysis

Abstract. The paper presents an "L-type" leg applied in SiGe/Si Multi Quantum Wells (MQWs) based bolometer. Characterization structure has been designed to take measurement for α-SiNx:H film stress. The displacement of beam endpoint in the structure is 0.48 micron and the interior stress is about 87 MPa totally through generalized Hooke law. Furthermore, the mechanical analysis for SiGe/Si MQWs based bolometer has been taken and the largest stress is about 600 MPa in the calculation. The bolometer SEM photograph is shown at last.

Introduction

Bolometer plays a pivotal role in uncooled infrared detector [1-2]. Many researches have been reported in last two decades to improve the performance [3-4]. All of them are based on the 'bridge' structure published by Honeywell in 1992. Thermal performance analyses have been focused in researches because pixel is immobile in working state which means few mechanical supporting and large deformation issues should be taken into account in most case. Shorter width and longer length of supporting legs contribute to improve the thermal conductance which leads to higher static response [5]. The limited dimension in contact lithography is about one micron and the leg width less than two micron should be difficult with several alignments in MEMS process.

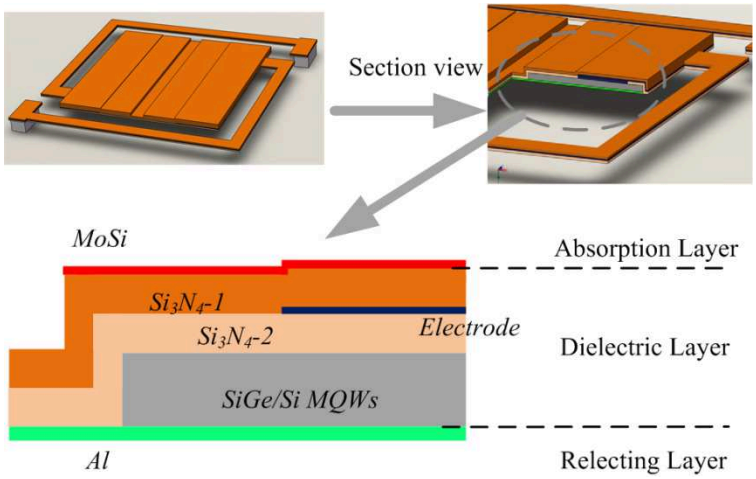

Fig.1. "L-type" supporting leg applied in SiGe/Si Multi Quantum Wells (MQWs) based bolometer

The bolometer with SiGe/Si Multi Quantum Wells as thermistor has higher temperature coefficient resistance (TCR) and lower noise due to mono-crystalline silicon and silicon-germanium [6]. The structure is difficult and more than nine steps of lithography alignments are needed in the process [7]. To maintain the equivalent thermal performance, L-type beam as supporting leg have been present in the paper as illustrated in Fig.1. The leg with L-type beam has lower thermal conductance compared with straight beam. However, longer beam also leads to larger stress and the

α-SiNx:H (amorphous silicon nitride containing hydrogen atom) layer, employed as supporting leg, induces interior stress in PECVD (Plasma Enhanced Chemical Vapor Deposition) process. As a result, mechanical analysis and α-SiNx:H layer stress characterization should be taken into account.

The paper presents the stress formation mechanism and characterization structure for α-SiNx:H film. Both simulation and experiment results have been given. The interior stress of α-SiNx:H on SiGe/Si MQWs is about 100 MPa as the calculations. In the third section, mechanical analysis have been present and the scanning electron microscope graph of bolometer have been shown at last.

Stress Characterization of α-SiNx:H layer

α-SiNx:H layer is employed as mechanical supporting layer in the structure. However α-SiNx:H layer manufactured by PECVD always have interior stress. The stress formation mechanism is always classified into intrinsic stress and thermal stress. Thermal stress induced due to the mismatch of coefficient of thermal expansion between α-SiNx:H and SiGe/Si MQWs. Intrinsic stress during PECVD are dependent with temperature, RF power frequency and reactive gas flow rate. The higher growth temperature has a positive influence on the structure of films [8]. However, the temperature should be less than 300℃ due to the limited temperature of read-out circuits in the substrate. The high frequency thin film residual stresses performance as tensile stress, yet the low frequency thin film residual stresses performance as compressive stress. In the experiment, the α-SiNx:H was deposited by high-low frequency alternation RF power to compromise the intrinsic stresses. The parameters are list as follow.

Table I α-SiNx:H deposition process parameters by PECVD

Flow rate (sccm)			Pressure	High RF Frequency		Low RF Frequency	
SiH4	NH3	N2	(mTorr)	Frequency(MHz)	Power(W)	Frequency(kHz)	Power(W)
13.5	10	1000	1700	13.56	67	380	53

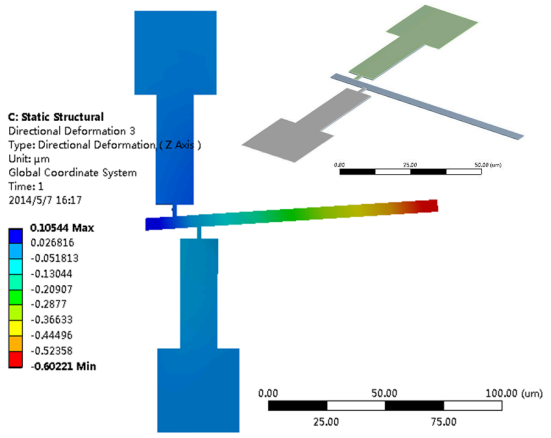

Fig.2. The beam displacements of α-SiNx:H film stress characterization structure in simulation

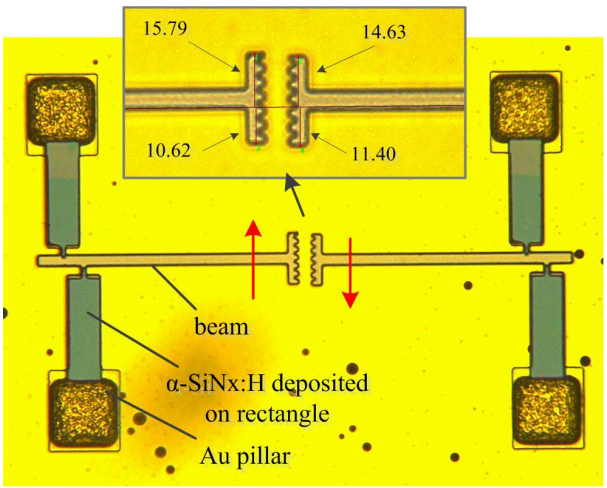

Fig.3. The photograph of film stress characterization structure after process.

The stress characterization structures are designed as shown in Fig.2. The α-SiNx:H film was deposited on rectangle substrate, SiGe/Si MQWs. The deformation of the rectangle was reflected on the displacements of long beam, on which there is no α-SiNx:H. All of the structures mentioned above are suspended and supported by Au pillar. The displacement amplification of beam endpoint is 0.48 micron by lever structure. The structure in simulation is 0.60 micron which is similar to experiment results. According to generalized Hooke law, three-dimensional stress-strain (σ-ε) relationship is expressed as Equ.(1).

$$\begin{pmatrix}\varepsilon_x\\ \varepsilon_y\\ \varepsilon_z\end{pmatrix}=\frac{1}{E}\begin{pmatrix}1 & -\mu & -\mu\\ -\mu & 1 & -\mu\\ -\mu & -\mu & 1\end{pmatrix}\begin{pmatrix}\sigma_x\\ \sigma_y\\ \sigma_z\end{pmatrix} \quad (1)$$

where E and μ is Young's modulus and Poisson's ratio of α-SiNx:H material. The interior stress is about 87 MPa in the calculation.

Mechanical Analysis for SiGe/Si MQWs based bolometer

L-type beam as supporting leg has lower thermal conductance compared with straight beam, which has lower demand of lithography alignments accuracy during process. However mechanical analysis is necessary for L-type supporting legs. Bolometer is immobile in working state and gravity has few influences on the structure. The interior stress of α-SiNx:H layer is about 87 MPa in stress characterization mentioned above. The simulations have been conduct and results are illustrated as shown in Fig.4 to Fig.6.

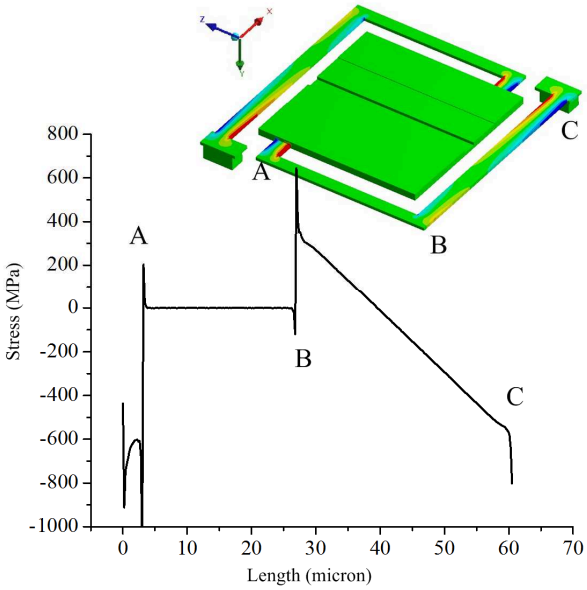

Fig.4. Stress distribution of supporting legs along x-axis

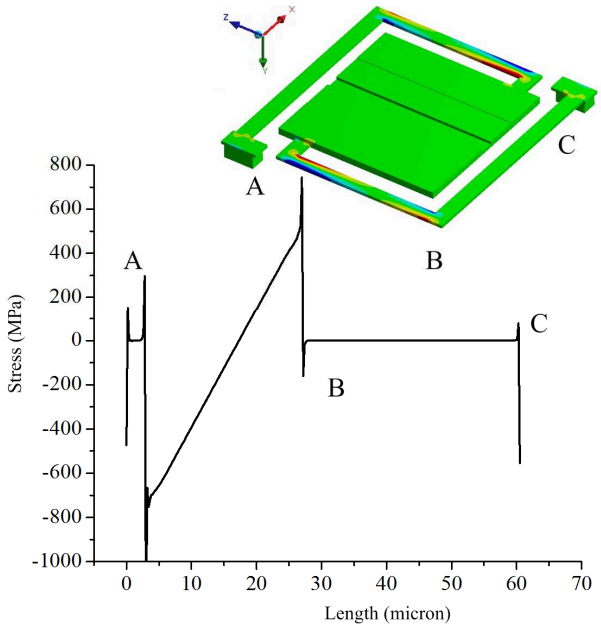

Fig.5. Stress distribution of supporting legs along z-axis

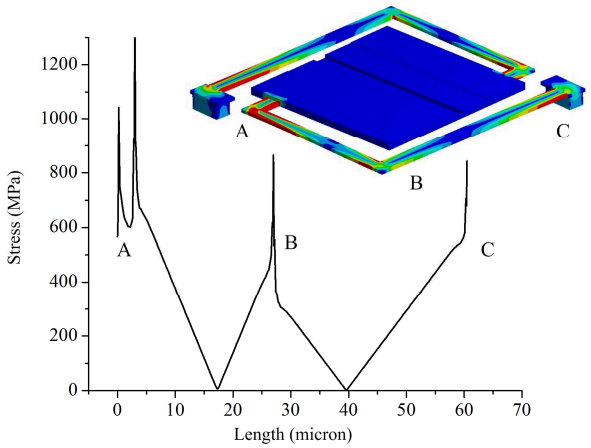

Fig.6. Stress intensity distribution of supporting legs

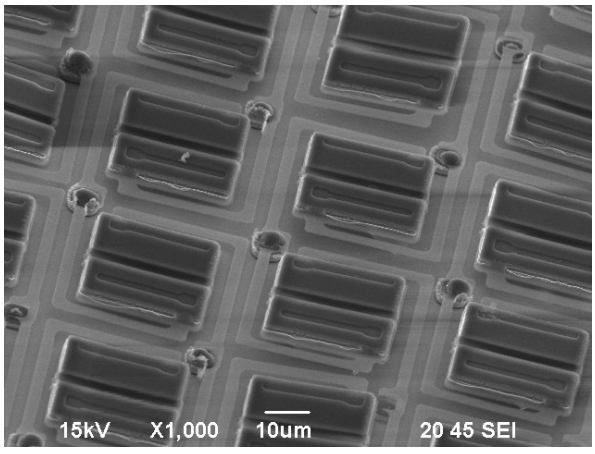

Fig.7. SEM photograph of bolometer

Stress distributions of supporting legs along x-axis and z-axis are illustrated in Fig.4 and Fig.5. Film stress valued with 87 MPa applied on the L-type legs. Stress along x-axis from B-C take a dominant position due to bending moment along y-axis. The same situation happened about the

stress along z-axis. Summarized, the stress intensity distribution is illustrated in Fig.6 and the point A, B, C is the place where maximum stress occurs. The maximum value is less than 600 MPa, which meets the requirement of mechanical supporting. There is no obvious deformation or distortion as shown in Fig.7.

Conclusion

The paper presents an “L-type” leg applied in SiGe/Si Multi Quantum Wells (MQWs) based bolometer. The stress measurement and analysis of “L-type” leg were conduct and the interior stress is about 87 MPa with the experiments and the calculation through generalized Hooke law. Stress distributions along two directions have been analyzed and the maximum value is less than 600 MPa which meets the requirement of mechanical supporting.

Keywords: Aircraft hydraulic systems; hydraulic pipe; failures; Oil Pollution

Abstract. The hydraulic system of Aircraft is an important power organization and plays an important role in the process of airplane operation. The failures of the airplane have the character of concealment, complexity and uncertainty. So if the hydraulic system ran out of order it not only cause huge casualties and economic losses, but also has a long and low efficiency maintenance cycle. This text analyzes the common causes of the failures and the failures that newly appeared of the aircraft hydraulic systems in detailed. Some of effective solutions have been proposed which quicken accelerate the speed of fault diagnosis and improve the efficiency of aircraft maintenance.

Introductions

The failure of the airplane characterize by its concealment, complexity and uncertainty. Therefore if the plane hydraulic systems go out of order, it will have a long and low efficiency maintenance cycle. With the development of the modern aircraft industry, the hydraulic structures of the plane are becoming more and more complex, it also increase the failure probability of the aircraft hydraulic system.

Recently a new kind of diagnostic technology has been emerged. The method of the technology is to giant information with the sensor and signal measurement technology. Using computer and a variety of testing instrument to establish the mathematical model and dealing with the data. But Mathematical model of the method is very complex in addition to its uncertainty and external disturbance. In some cases, the model even cannot be established. So knowing common failures of the aircraft and the corresponding solutions will significantly shorten the maintenance cycle, reduce the maintenance personnel technical level and improve the economic benefits.

Division of aircraft failures

The paper analyzes the failures of the aircraft from aspects of oil pollution, hydraulic pipe fracture, high oil temperature and leakage in detail. Some of the corresponding solutions have been put forward in order to improve the maintenance efficiency.

Oil pollution. The oil pollution means that oil mix with solid particles, water, gas, chemicals materials and some microbes etc. The most serious pollution is solid particle pollution. The foreign statistical data shows that 60% contaminants coming into the hydraulic system when the installation process. The pollutants draw into the system in the regular maintenance Accounted for 20% and the granules produced by parts natural wear accounted for 20%. The Airplane crashes that caused by hydraulic system failure be up to 90% [1].Therefore the solid particle pollution is the mainly responsible for the trouble of hydraulic system, and it is also the key of routing maintenance.

The first source of the particle contaminants come from outside of the system. In the process of assembly, disassembly and daily maintenance, some of the polyester fibers and solid particles will attach to the piston rod, or through the vent pipe mouth coming into the oil tank and caused oil pollution. The second kind of the pollution particle is cause by the parts wear. When the system working in high temperature for a long time the oil would be oxidized and produce colloidal sediment. The Third kind of Pollutant is residual pollutants. These contaminants have already

existed before the system assembled such as iron filings, welding slag and cotton fiber. It is difficult to completely eliminate and would throughout the hydraulic system when the aircraft working [2].

Aircraft hydraulic system Components must be cleaned before installation with silk cloth instead of cotton and linen material cloth. In order to avoid fiber stranded on the surface of the parts and then introduce into the hydraulic system.

Oil filter should be used properly. The hydraulic oil filter should be selected according to hydraulic system pollution level. Generally, there are three oil filters in the aircraft hydraulic system, 1 for supply pressure pipeline, 2 for oil return pipeline. In order to avoid pollutants entering the hydraulic system the oil should be infect into the system from filter whose absolute precision above 3um. New type of filter element has been widely used in aircraft for the purpose of improving the ability to filter out dust. Metal rubber is a new type of elastic and porous material and made up of metal wire via special preparation process. It has the advantage of high bearing capacity, anti-clogging ability and the pressure continuous adjustable performance of its throttling pore. The new material has been used oil filter making.

Tube fracture. From analysis of aircraft accidents caused by hydraulic tube broken recent years Aircraft maintenance engineer knows that the tube broken actually is a kind of fatigue fracture.

Fig. 1: Wrinkles in hydraulic pipe wall of airplane

Fig. 2: The micro cracks on the tube bell mouth

Most of the damaged places are the area where there have stress concentration such as unreasonable hydraulic pipeline designing, too much Bending or fold appear on the inside wall of the oil-pipe (refer with: Fig. 1).The main reason of the tube broken is that the aircraft hydraulic system working in the high pressure, big flow pulse, huge hydraulic impact and high-frequency pressure oscillation environment. For this reason the oil tube of the system will fatigue breakdown by suffering of radial vibration and bending vibration.

Firstly, the size and the material of the hydraulic tube must be chosen according to the pressure requirements. In normal conditions, high pressure system should choose stainless steel tube and aluminum tube. Rubber hose always used in low system and scavenge oil system. Much attention should be paid to when choosing a hydraulic pipe; the surface of the tube must not have the obvious machining tool, micro cracks and other defects. Fluorine plastic pipe can also be used in hydraulic section where Stainless steel tube difficult to install or the places with big pressure pulsation and vibration [3].

Secondly, in order to avoid the faction between the tubes, the proper gap should be keep between them. In the process of installation do not install forcefully when the tube are not aligned, in case of stress concentration and crack produced on the bell mouth and the surface of the bend(refer with: Fig. 2) [4].Thirdly, a support frame should be installed at the area where prone to come about resonance. It is the effective way to solve pipe resonance and avoid hydraulic pipe fatigue cracking.

Leakage. Aircraft hydraulic system is using liquid oil as the working medium, so it has been accompanied by the problem of oil leakage from the date of the birth. The reasons that cause hydraulic system leakage and corresponding solution showed as below.

Fig. 3: Connectors can't be totally matched

Fig. 4: The complex layout of aircraft hydraulic pipe

Firstly, untight seal of connection join would cause pipe leakage. Screw the pipe connection tightly when connect hydraulic pipe line. But screw too tight will destroy interface of the screw thread and lead to leakage. The tightening force usually ensured by the torque spanner in engineering. Unmatched thread of the connectors can also result in leakage in system. In the process of installation and maintenance of the airplane, different criteria thread cannot be matched and some threading connector with same size can't be matched together because of their different pitch and number (refer with: Fig. 3).

Secondly, sealing ring failure can also lead to leakage. This is mainly because the bad sealing environment. Hydraulic oil has the character of corrosive especially when system works for a long time in high temperature. The high temperature oil will accelerated the oxidation and corrosion loss of the rubber sealing ring. So in the aircraft daily maintenance the sealing ring should be checked out and replaces them when they have defects.

Thirdly, unqualified maintenance behavior can also give rise to leakage. During the pipe installation, tightening torque does not conform to the requirements and inappropriate tools using will cause causing hydraulic system leakage, therefore, in the process of daily maintenance must be carried out accordance with the manual strictly.

High oil temperature. In the hydraulic system, high oil temperature will also lead to the oxidation and decomposition of hydraulic oil. It is also the important source of oil pollution. The high oil temperature will aggravate aging failure of the sealing device. So high oil temperature is an important reason that causes hydraulic system failure. The reason of high oil temperature and the corresponding solution shown as blew.

Firstly, unreasonable layout designing of the attachment will rise system temperature. Because the hydraulic pump working through drive of the engine rotor rotation, many hydraulic accessories and tubes are installed around the engine compartment. The engine will generate lots of heat and rising the temperature around when it working. Secondly, the complexity of the tube line and too much turning will cause oil hit in the process of flow, a lot of kinetic energy is converted into heat, which is an important reason of high temperature of hydraulic system oil(refer with: Fig. 4).

In currently aviation industry, there are two solutions to control hydraulic system temperature. The first way is to increase heat dissipation and the other method is to reduce the energy loss. In general machinery, the tank capacity could be increased in order to accelerated heat dissipation. But the planes have a strict requirement of space. So the method of increasing the capacity of the tank is not feasible in the aircraft. At present, the most successful technology is to arrange the export

pipeline of the pump to the lower temperature area (the plan wings) and then go back to tank. Using AMESim simulation software to analyze the thermal characteristics of airplane hydraulic system, the result shows that the temperature of back pipe line which arrange at wing drop nearly 8 degree [5]. So some of the hydraulic accessories and pipeline should be arranged in the places where the environment temperature is lower. For the catheters that have to install in the high temperature environment, heat insulation measures should be taken to control the oil temperature. If the heat mainly comes from the radiation of engine, insulation board with lower black degree coefficient or multilayer insulation measures can be used to reduce the heat [6].

Conclusion

Solid particles pollution of oil, pipe fracture, oil leakage and high temperature can lead to aircraft failure and causing serious consequences. In order to avoid the occurrence of the above problems, effective measures is not confined to the daily maintenance but also embrace the process of aircraft designing, parts producing and assembling. Before the designing, some method should be prepared to deal with the failures with high probability. To the problems that have already happened the maintenance technicians should take measures according to the method proposed.

Keywords: Remote Control UAV; Flight controller; LabWindows/CVI; GL Studio

Abstract. To provide UAV's operator with flight information in real time, according to the property of remote control UAV and human-machine interface design, a flight controller has been implemented. The flight controller used LabWindows/CVI, GL Studio and UDP communication as the main developing platform. The system has been used in projection, and the test had showed that it could meet the need of the GCS(ground control station) of remote control UAV.

Introduction

The remote control UAV is one kind of UAV that can either fly remotely, and can also be controlled by the GCS(ground control station). The flight controller is the "nerve center" of the system, and the hub of human-computer interaction [1]. The controller is consist of background data processing and foreground data displaying. The former is remote telemetry data interacted with ground control system by UAV. The interactive data will be precisely, vividly and intuitively displayed on the human-computer interaction interface. The flight controller developed by LabWindows/CVI is embedded with the GL Studio controls, it uses UDP protocol for data communication. It provides the human-computer interaction platform for the ground controlling staff, conveniently control in real-time.

1. Development environment

LabWindows/CVI based on C language is a virtual instrument software development tool developed by the NI company. It has advantages of high efficiency, fast interface design, powerful language and flexible performance. It is well applied to the establishment of systems detection, automatically detecting environment and signal analysis processing, especially for the development of complex testing system. In addition, LabWindows /CVI also has a strong capacity of network communication data transmission, which provides the API function based on UDP communication protocol to realize the efficient, reliable, connection-oriented data communication network [2] .

GL Studio is developed by DISTI company for instrument simulation. It is used to develop real-time, two -dimensional or three-dimensional, photo-realistic and interactive graphical interface software [3]. GL Studio is consist of two parts: the graphical interface designer and the code generator. A graphical designer allows operator to draw the graphics system quickly and easily ,and use the intuitive way to complete the appearance and interaction design of graphic panels; the code generator draw the graphic look of object interaction to generate c + + / OpenGL source code, then become dynamic controls.

2. Functional analysis and the design of human-computer interactive interface

2.1 Functional Analysis

The flight controller plays an important role in UAV flight, real-time display is its main function. The controller save the information of flight attitude and flight parameters, send state monitoring, remote data regularly and control the flight status. Operators can effectively control the UAV through the platform to ensure the normal work of the UAV platform. According to the functional requirements, overall structure design of flight controller is shown in figure1:

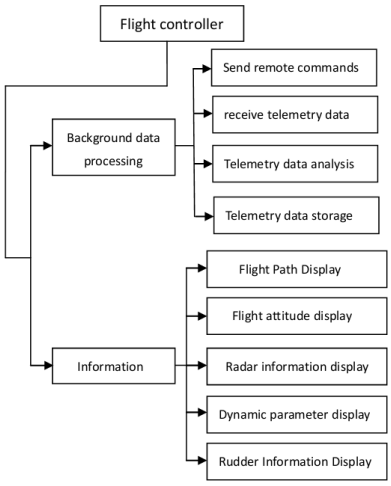

Figure1: Structure drawing of flight controller

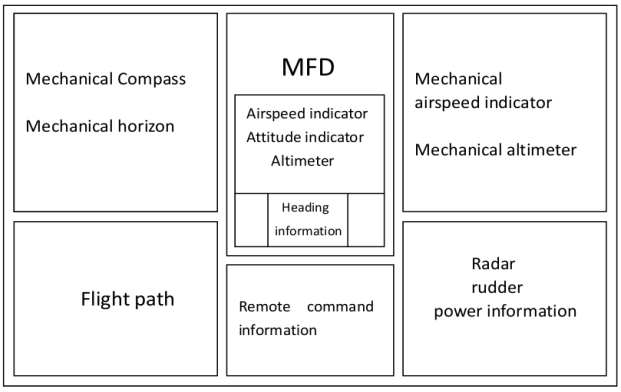

Figure 2: Interface layout of flight controller

2.2 Design of human-computer interactive interface

The flight controller provides important flight parameter, operator handle the UAV on the ground on the basis of the information. Therefore, the data display and the layout of panel are extremely important. The flight controller is modeled based on the U.S. military standard MIL-STD-1787C [4] and principles of human-computer interface design [5] of aviation.

The compass, horizon, airspeed indicator, altimeter and MFD (Multifunction Display) are developed by GL Studio. The 4 mechanical instruments provide a backup for the MFD, that is, if there are problems in the electronic instrument, mechanical instruments can still display flight attitude information, so that you can continue to manipulate the UAV. Flight path: It is used to display the track within a specified area. When the target appears, the radar display the distance and direction of the aircraft. Rudder, elevator and other parameters are displayed in the aileron control surface. Parameters such as engine speed, amount of remaining oil will be shown in dynamic information monitor.

3. Software design and implementation

The flight controller is mainly developed by LabWindows/CVI platform, embedded with the dynamic control developed by GL Studio [5]. The data communication is realized by using UDP. We initial the data-driven screen by using the main thread and only use the UDP event mechanism sequence control method. The software process is shown in Figure 3.

3.1 Communication between flight controller and the ground terminal

Because of the flying machine data transmitted between the flight controller and the ground terminal is relatively small, but the high demand of real-time data transmission (sending and receiving data processing must be completed in every 20ms), we chose the UDP protocol.

The UDP protocol was packaged by LabWindows / CVI. When the aircraft receive data from the ground terminal, an event has been triggered. Then the callback function was invoked automatically. Callback function process the telemetry data, control the drive of GL Studio and send the remote data. Finally, we realize the real-time communication between flight controller and ground terminal [6]. The format of telemetry data during the communication is shown in the figure 4.

Among them, area A is data frame header; phase 2,3,4-byte in area B are of the same content, all of them are telemetry data category; area C stores telemetry data, it will put the result (5 to 21 byte checksum) on the position of the 22th bytes; area D is the tail. Detailed instruction of frame header, data, categories, telemetry data storage format and frame tail are explained in the communication protocol. Remote data frame is defined similar to the telemetry data frame.

When the flight controller receives downlink telemetry data, it will first determine whether the frame header, data length and frame tail are consistent with the protocol, if so, the data frame can be received. Then it determines the data from area B: if the contents (2 to 4) are the same, they are considered as the same data type in area C, data from the area C are parsed according to the protocol; if the three bytes of data are not identical, the contents of two bytes are considered as the data type in area C, repeating the above steps; if the three bytes of data are completely different, the frame data should be discarded and the controller is ready to receive the next frame data. Key code:

```
datanumber=UDPRead(channel,buff,bufsize,timeout,sourcePort, sourceAddr);
if((datanumber==DATANUM)&&(buff[0]==0xxx)&&(buff[1]==0xxx))
{
……// Further judgment and data processing
}
```

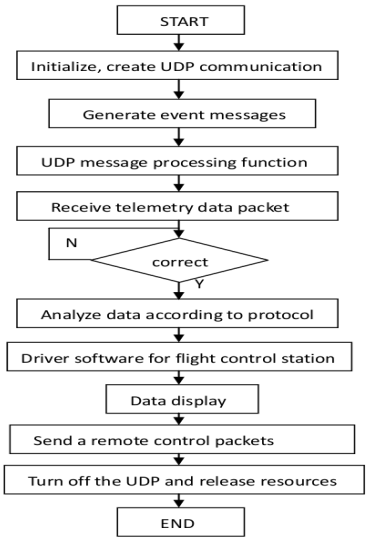

Figure 3: Flow chart

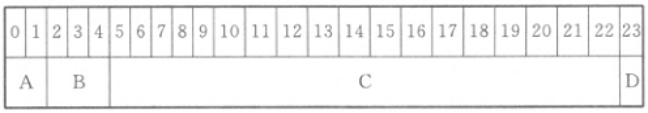

Figure 4

3.2 The development and encapsulation of GL Studio controls

When developing dynamic controls in GL Studio, you need to select "GL Studio Live Component" if you create the project (generate the dynamic component). After creating behavior code and adding external data interface for each section, the model need to be debugged, compiled and linked, then the *.dll dynamic file types are generated. Finally, encapsulate and generate control.

1) We can add an external data interface by creating a sub function with the property of "property" in the main control window, and the external data can drive the control through function calls by other software. External data interface function is as follows:

```
void rotateClass:: data_interface (const float& value)
{
…….; }
```

Data_interface is the name of the external data interface function and is the property created for controlling; float is the type that can drive control of external data. The above two can be created and set as needed.

2) Control encapsulation: control encapsulation is to make *.Cab file. The generated DLL file should be packaged by the written file (make_cab. Bat), the contents of the package include two:

1. The *. DLL files;

2. VC files provided by GL Studio. Version associated with GL Studio version and the version of VC + + should match each other.

Writing make_cab.bat program according to the file path and file name. Its main contents are as follows:

"%GLSTUDIO%\bin\cabdev\bin\cabarc.exe"-s6144N" (generate the name of control， for example: example.cab)" "(document storage path, for example: D:\example\debug\example.dll)" "%GLSTUDIO%\bin\glstudio3_2_1_vc60.dll".

Among them, cabarc.exe is the packaged application provided by GL Studio, the example.dll and glstudio3_2_1_vc60.dll are packaged to generate example.cab file when the program is automatically called, then the encapsulation of control has been done.

3.3 Embed GL Studio controls to CVI

The GL Studio controls are embedded in LabWindows / CVI, Specific steps are as follows:

1）Add an ActiveX control into CVI to load *.cab file;

2）Create GL Studio drive function and load it;

3）Filling in the control path location and adding controls ;

4）Edit properties of control;

5）Add the appropriate behavior code and driver controls in the "*. C" file.

The main code is as follows:

```
/ / Get the GL Studio control handle and driven by an external data
GetObjHandleFromActiveXCtrl(panelHandle, PANEL _GLSPLAYER, &objhandle);
/ / Data type conversion
CA_CStringToBSTR ("data_interface", & str);
/ / Conveying external data to the control
GLSPlayerLib__DGLSPlayerSetAttrib (objhandle, NULL, CA_VariantBSTR (str), CA_VariantFloat (rdata [0]));
```

Among them, the STR data type is BSTR. rdata [] stores the data which UDP received.

4. System verification

Detecting results show that the flight controller can receive, process and display the remote data correctly. Virtual instruments developed by GL Studio are also working properly; the controller can sent the remote control commands correctly, fast and timely to the ground terminal when clicking the takeoff, climb, level off buttons. The design of flight controller meet the functional requirements of ground station system.

5. Conclusion

The design and development of the remote control UAV flight controller has certain universality, it solves the problems in the complexity of data-driven scene and the real-time communication. The flight controller give full play to the advantages of LabWindows/CVI and GL Studio, improve the quality and speed of development. According to military specifications and human-computer interface design principles, we fully consider the visual information acquisition characteristics of the operator, implement the information classification, prioritize location layout, improve the efficiency of achieving information, reduce the fatigue. As a result, the flight controller improve the Operational efficiency of the UAV to a certain extent.

Study of AT based on the lever method

Jiangjiang Li , Jinghua Li

TianJin Vocational Institute,Tianjin,300410,China

Keywords: Design reasonableness of transmissions;Lever method;Improvement of design of transmissions;Drive scheme

Abstract. The rotation speed and shift process of automatic transmission were analyzed intuitively based on lever method in this paper, the design reasonableness of transmissions was verified as well; At the same time the measure of improvement of design of transmissions scheme was put forward.

Introduction

Lever method is a simple analytical method conducting to analyze planetary mechanism about their kinematics and dynamics . Based on the lever method analyze, the shift process of AT, especially its reasonable design of transmission scheme ,can get a comprehensive analysis.

The analysis with shift process of automatic transmission(example of WV 01M AT)

The related information about 01M AT. The related shift data about 01M AT shown in table 1 and figure 1:

Table 1 The movement of implementation components of each shift of different gears

Gear(trasmisson ratio)	B1	B2	K1	K2	K3	F0	K0
1H（2.714）			⊙			⊙	
1M（2.714）			⊙			⊙	⊙
2H（1.507）		⊙	⊙				
2M（1.507）		⊙	⊙				⊙
3H（1.000）			⊙		⊙		
3M（1.000）			⊙		⊙		⊙
4M（0.7037）		⊙			⊙		⊙
R（-2.375）	⊙			⊙			

Note: □Said work

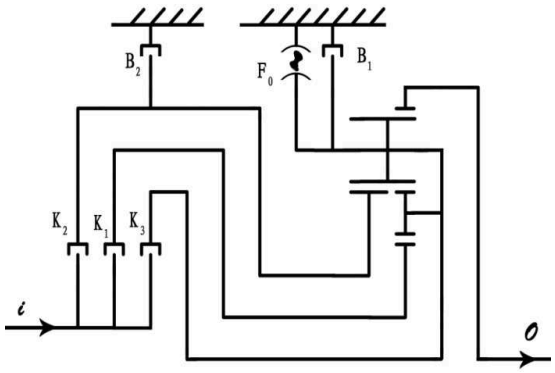

Fig.1: The transmission diagram of 01M AT

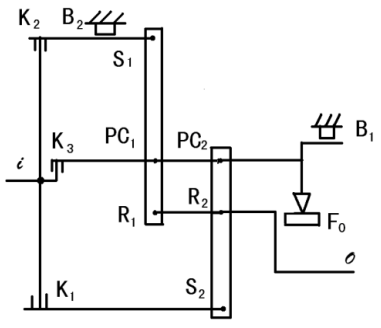

Fig.2:The lever figure of 01M AT

According to the information above, it is easy to make out lever diagram of 01M AT, as shown in figure2:

Figure 2 explanation: S1 is the sun gear of the front row, PC1 is planet carrier of front row, R1 is front row's ring gear, PC2 is rear planet carrier, R2 is rear ring gear, S2 is the rear sun gear; From the

lever figure we know that the front planetary row is planetary gear row, rear planetary row is double planetary gear row. The whole institution is the typical ravi type gear train institutions.

The analysis of rotate speed of each gear about 01MAT. According to the figure ,there has the drawing about equivalent lever speed figure of 01M AT ,as shown in fig.3:

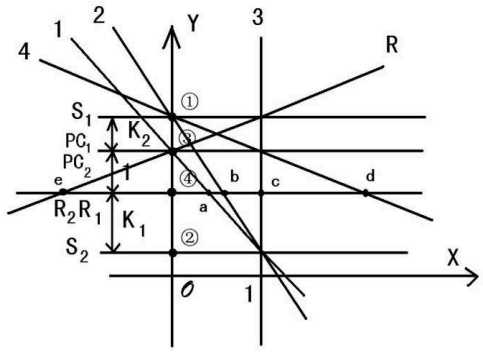

Fig.3: The equivalent lever rotate speed figure of 01M automatic transmission

Figure 3 explanation: the node ① represents S1 component, the node ② represents PC1PC2 component, the node ③ represents R1 and R2 component, the node ④ represents S2 component. The distance of 01 on the X axis represents the input shaft rotate speed to be 1. 1,2,3,4 respectively represents 1st, 2nd, 3rd and 4th gear.

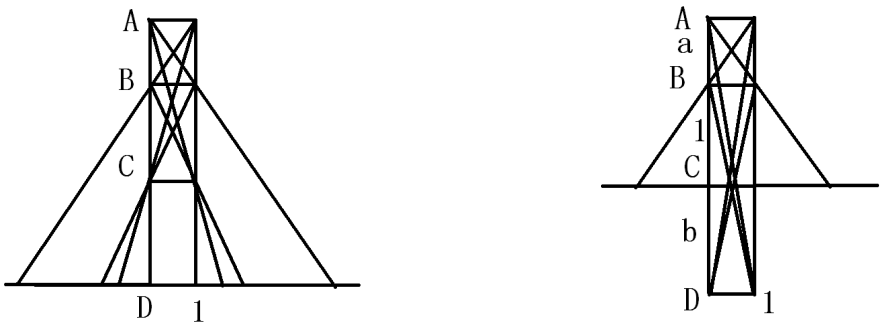
$$K_2 = \frac{ZR_1}{ZS_1} \tag{1}$$

$$K_1 = \frac{ZPC_2}{ZS_2} \tag{2}$$

We have following conclusions according to the equivalent lever speed fig.3 about 01M automatic transmission:The output rotate speed of 1st divides the input rotate speed of 1st is the distance of oa in the X axis: $oa = \frac{1}{K_1+1}$; The output rotate speed of 2nd divides the input rotate speed of 2nd is the distance of ob in the X axis: $ob = \frac{K_2+1}{K_1+K_2+1}$; The output rotate speed of 3rd divides the input rotate speed of 3rd is 1; The output rotate speed of 4th divides the input rotate speed of 4th is the distance of od in the X axis: $od = \frac{1+K_2}{K_2}$;The output rotate speed of R gear divides the input rotate speed of R gear is the distance of oe in the X axis: $oe = -\frac{1}{K_2}$,direction is the opposite.

The analysis of rationality of transmission scheme about 01M AT.

The analysis of design's rationality of transmission scheme about 01M AT based on lever method:



a) Endpoint output b) Intermediate point output

Fig.4: The analysis of equivalent lever of output point

01M AT belongs to three freedom of motion and the structure of double planetary row, from the perspective of output point, which has two kinds of possibility, as shown in fig.4:

Making end point A (A and D, 2 points are equivalent) as output point (as shown in aof fig 4); Through the analysis of lever transmission, it shows that there are 3 reverse, 3 overdrive, 1 directly gears, but no deceleration gear, so this kind of scheme of making endpoint as output point doesn't work obviously.

Making end point B(BC, two points are equivalent)as an output point(as shown in b of fig.4). Comprehensive form such as shown in table2, all kinds of transmission schemes: AB=a, BC=1, CD=b.

Table 2 The various states of transmission of making equivalent lever intermediate point B, C points as output point (except direct gear)

Serial numbers	Input points	Braking points	Transmission ratio	Remarks
①	A	D	(1+a+b)/b	deceleration shift
②	B	D	(1+b)/b	deceleration shift
③	D	B	1+b	deceleration shift
④	D	A	(1+a+b)/(1+a)	deceleration shift
⑤	B	A	a/(1+a)	overdrive shift
⑥	A	B	-a	reverse shift

Through the analysis of the table 2 and figure4, it shows that the transmission scheme of 01M AT adopts to be③④⑤⑥, when input points is changeless, only changing the braking points to realize the shift between deceleration gears. Rather than using ①②⑤⑥transmission scheme(by changing input points to shift between deceleration gears). Their transmission ratios are varies slightly between the adjacent deceleration gear as well, which is a reason that the shift smooth and manufacturing technology are greatly improved. From the above terms, undoubtedly ③④⑤⑥ transmission scheme is better than the①②⑤⑥transmission scheme. It could also be the designer's original intention of design of 01M AT. Other solutions are not comparable besides these two kinds of schemes of transmission design.

The inspection of rationality about the transmission scheme of 01N AT through the evaluation factors of transmission scheme. According to the literature 5 we know that: the evaluation factors of transmission scheme include: size parameters, process parameters, motion parameters and torque parameters etc.

The size parameters $K = \frac{Zr}{Zs}$, The value K directly affect the size of shape layout and weight of planet row, The value K scope is (1.4, 4.5), while the value K = 2.7, it is the best value; The process parameters $T = \frac{K\min}{K\max}$, The value T directly affect the manufacturing technology of gearbox and the scope is (0.33, 1), its value more close to 1, manufacturing technology will be better; The motion parameters $N = \frac{Ni(max)}{N_0}$, the size of the values of N is related to a bearing life, the value N scope is (0,3), the value N is bigger while the design requirement of bearing will be higher. The torque parameters $M_i = \frac{M_{max}}{M_0}$, The value Mi affect to be the required of strength and service life of the components, the value Mi should be as low as possible.

The value K of front planet row of 01N AT: K1=57/24=2.375, The value K of Rear planets row:

K2=36/21=1.714;T=K1/K2=0.722;N=2.714,which is transmission ratio of 1st gear; By the torque analysis we know that Mi=36/21+1=2.714.

Comprehensive three above aspects ,we can conclude that 01N AT which can realize 5 gears (include a reverse) possesses outstanding design in three dof double planetary gear mechanism.

Conclusion

Through the analysis above, it is clear that the leverage method is really more intuitive and convenient in the analysis of complex multiple rows of planetary gear in AT design and shift process performance than analytical method.

Design and analysis of hydraulic piston structure exciter

Shijuan Wang, Kelong Yu

Eaestern Liaoning University,Dandong118003，Liaoning118003,P.R.China

yukelong1966@126.com

Keywords: vibration, the piston movement, leakage and sealing

Abstract: The movement characteristics of hydraulic exciting piston is a small displacement and high reversing frequency. The movement of the piston is to adapt to the requirement of quick reversing resistance. The mating surface seal uses to reduce the motion resistance to meet the requirements of the piston movement. Piston position should be in the oil chamber oil area to meet the requirements of the piston movement and oil circulation. Elastic beam with hydraulic cylinder is connected together . This structure is conducive to the piston and the connection of elastic beam and the installation of the oil cylinder. The causes of the different moving displacement of piston is leaking.

Introduction

Hydraulic vibrator vibration by piston movement. The vibration frequency of hydraulic vibrator is relatively low, but can produce larger output power value. Apply to the vibratory pile driver, vibration shear machine as well as the larger power works required. The vibration of hydraulic vibrator output form is based on the output of the piston displacement as its vibration amplitude, repeatedly mobile number per unit time is its vibration frequency. Thus to realize the two conditions of hydraulic vibrator vibration is entering piston hydraulic circuit quickly reversing and piston moving smoothly. In design and operation of the piston vibration encountered problems and solutions are put forward.

The piston vibration forming elements and analysis

Piston under certain frequency vibration should as far as possible to reduce the resistance of the piston motion. Design of a piston sealed often from the perspective of leakage. Piston seal on the set up multi-channel time. The seal under the action of the oil pressure, low tightly affixed to the hole wall and the large resistance. Reduce the resistance of the piston can remove seals, the use of mating surface seal form, or by a single sealing ring seal structure. In order to reduce power loss of the movement process of piston[1].

Piston elastic locating method is installed in one end of the piston stress smaller elastic element and elastic beam. Does not the installation of the oil cylinder fixed cylinder body, piston movement. The piston movement can put the elastic beam with fixed cylinder body is an organic whole repeatedly. So we can put the elastic and cylinder, piston of a unit.

As shown in figure 1 for the working principle of hydraulic vibrator. Hydraulic vibrator is by the hydraulic oil cylinder and the rotation type directional control valve.

The diameter of the connecting shaft at the ends of the piston is not the same. The right end shaft diameter greater than the diameter of the left end of the shaft. According to the change law of pressure at the ends of the piston hydraulic oil can be seen. Piston right cavity is high pressure oil workspace. The working chamber of the liquid pressure is not change. The left cavity of the piston working liquid pressure is changing. The oil pressure in the work place life is through the rotary valve constantly changing the inlet pressure, formation of a piston moving back and forth. In the process of the mobile, the work pressure of piston is equal. Leakage impact on the movement of the piston is not. The piston moves to the left, left cavity for the low pressure cavity of the piston. Right of piston chamber for the high pressure chamber. This is the influence of the leakage is the piston amplitude decrease. When the leakage of the vibration of the piston will be difficult to continue[2].

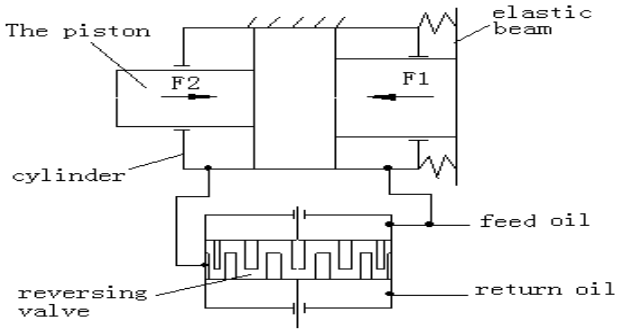

Figure 1. The working principle of hydraulic vibrator

According to the existing cylinder structure size. The diameter of the piston d=95mm, The sealing length $\ell = 5.75cm$,The piston and cylinder clearance $\delta = 0.7\times10^{-2}\,cm$

The oil of the severe : $\gamma = 0.9\times10^{-3}\,Kgf/cm^3$

The oil temperature 30°C，The oil pressure 3MPa. In 20 machine oil, for example. Kinematic viscosity of the oil ν=60 Li pool. According to the formula (1) calculate the leakage ΔQ[3]：

$$\Delta Q = \frac{\pi d\delta^3 \Delta p}{12\mu\ell}(1+1.5\varepsilon^2) \tag{1}$$

Type in the ： ε —The relative eccentricity gap

The structure of a rotary valve size: $d = 1.2\times10^{-1}$ m, $\ell = 5.75\times10^{-2}\,m$; $\delta = 7\times10^{-5}\,m$

The pressure difference：ΔP=3Mpa.The oil temperature t=30°C，The oil viscosity.

The dynamic viscosity of 20th hydraulic oil μ=1.8× $\mu = 1.8\times10^{-2}\,Pa\cdot s$

When the gap of relative eccentricity epsilon take 0.5 when calculating leakage are respectively $4.16\times10^{-5}\ m^3$ /s.This relative to the hydraulic pump output flow leakage is permitted. Piston leakage to the influence of vibration can be determined by the clearance between the piston and cylinder hole. The influence of the clearance is to leak to the influence of the piston displacement.

The piston is not the cause of the vibration piston end face contact with the cylinder face. Piston end face contact with the end of the cylinder rigid limit of piston displacement. Will be moved to the middle of the oil cylinder piston position, piston vibration. This phenomenon shows that the two content

One is the position of the piston to move. The piston vibration need a balanced position. The second is the piston itself cannot be rigidly. The piston can overcome force cannot be more than the most strongly from the piston. Otherwise the piston will lose excitation function.

Analyzing the piston to move right

If good seal piston in the process of vibration should shift to the left should not moves to the right. Can be showed by the following calculation:

The piston to the left movement of the thrust

$$F_1 = \frac{\pi}{4}(d^2 - d_1^2)p = 32.398\,p$$

Type in the: d —the piston diameter,95mm.

d_1 -- the left end diameter of piston rod,70mm。

The piston movement to the right of thrust

$$F_2 = \frac{\pi}{4}(d_1^2 - d_2^2)p = 25.918\,p$$

In the formula： d_2 -- the piston rod diameter，40mm.

Hydraulic system of the oil pressure under certain conditions, $F_1 > F_2$. So in the piston movement of a loop, mobile distance is greater than the distance to the right to the left. In fact in the process of the vibration of the piston piston moves to the right. Analysis of the cause of leakage is impact factor.

The piston moves to the right, the piston cavity pressure equal on both sides of the work. There is no leakage. Therefore, to the right total thrust F_2 is equal to the theoretical calculation values. On both sides of the piston cylinder volume change no leakage and the effect of the movement of the piston is associated with total thrust. The piston moves to the left, on both sides of the piston pressure difference exists. Working cavity leakage between the piston. Leakage is made by high pressure flow to the low pressure cavity. Due to leakage, high pressure cavity oil pressure ΔP, so the movement to the left when the total thrust F_1 is not equal to the theoretical calculation values. Due to the leakage at the same time, on both sides of the piston cylinder volume change affected by the spill. The piston of the actual displacement caused by the piston moves to the right[4].

In fact, the piston is working, inlet pressure fluctuations ΔP =1MPa. Assumes that the oil pressure of hydraulic system p =3MPa. Leakage caused by the piston working pressure =2MPa. The results is $F_1 < F_2$.

According to the structure of the piston can explain the reason of the piston moves to the right. In the piston movement of a cycle, the piston moves to the left, left the oil chamber of piston by flowing through the rotary valve oil distribution into the mouth rotary valve of low pressure cavity. Piston moves to the right of the rotary valve and pressure chamber high pressure oil by rotary valve oil distribution mouth to the left oil cavity of the piston[5].

In fact, when the piston moves left, on both sides of the piston pressure difference exists. The piston leakage between two working chamber. When the piston moves to the right, the pressure on both sides of the piston are equal, there is no leakage. When the piston moves left, the rotary valve oil distribution mouth oil discharge amount is quantitative. The piston right cavity left cavity leakage into the oil. So the piston left cavity clean oil discharge quantity decreased. When the piston moves to the right, the rotary valve oil distribution mouth feed and quantitative. The piston does not leak, so the piston moves to the right quantity is big, thus in the process of the vibration of the piston, the piston to the right.

Conclusion

Piston under certain frequency vibration should reduce the resistance of the piston motion. The piston rod with one sealing ring seal and the seal leakage of oil into the low pressure oil .

Using elastic beam is the necessary components to maintain the piston vibration. Elastic beam is connected to the cylinder body.The piston unit structure is compact.

Compared with ordinary mobile piston vibration,the displacement of a vibration piston is small and high frequency direction change. The piston in the reversing impact force is large. Should be used as much as possible with the face seal. The piston mating surface seals are used.

The influence of the leakage of piston on displacement should be controlled within the allowed number.

Design of Underground Gas Concentration and Humidity Monitoring System Based on RS-485

Long Yuehong

College of Electrical and Information Engineering,Anhui University of Science and Technology ,Huainan 231001 China

Keywords: monitoring of gas concentration and humidity underground coal mine;MJC4/3.0L; HS1101; RS-485;RS-232;upper computer

Abstract: In order to achieve long distance monitoring of gas concentration and humidity underground coal mine,a new monitor of gas concentration and humidity,which contains upper computer,master station and a lot of monitoring points,is designed.Every monitoring point is consisted of gas concentration sensor MJC4/3.0L and humidity sensor HS1101,which is used to conveys the data to master station by RS-485,again by RS-485 transmitted to the upper computer and it realizes the real-time monitoring of gas concentration and humidity undereground coal mine.

Introduction: Recent years,gas accidents are happening with a high frequency,this has caused a certain number of casualties and economic losses and at the same time the environment underground the coal mine is the basic working conditions for miners and has a direct relationship with the miners's safety and the efficiency of the mine production.So to realize a real-time monitoring of the coal mine gas concentration and the humidity of the coal mine working face has a very important significance[1].Then a new type of detector composed of upper computer and multiple monitoring device has been designed.This design includes a main unit and multiple monitoring points.RS485 communication has been adopted between the main unit and the monitoring points.Distributed layout has been used in the process of actual installation.The main unit is mainly responsible for collecting the gas concentration and air humidity of the monitoring points ,and then transmit the collected data to the upper computer through the 485 bus.

If the upper computer uses the RS232 communication interface, a RS485 RS232 converter should be added to complete the protocol conversion. Each monitoring point is consisted of the gas concentration sensor MJC4/3.0 L and the humidity sensor HS1101. It's used to monitor the downhole gas concentration and the humidity of the air, and transmit data to the the master station via RS - 485 in order to realize the real-time monitoring of the gas concentration and the humidity underground coal mine.[2]

1.The overall design of the gas concentration and mine humidity detection system

The gas concentration and mine humidity detection system is mainly composed of upper computer, the main unit and multiple monitoring equipments. Each test equipment contains multiple monitoring points and the sensor of monitoring point is mainly composed of gas concentration sensor MJC4/3.0 L (catalytic combustion type gas sensitive element) and precision electric air humidity sensor HS1101. The two kinds of sensors of each monitoring point transmit the collected data values to the singlechip in the form of analog.The analog value the sensor transmits is 0-5 v voltage in this design. Design of the analog voltage reference should be paid attention when the simulation sampling circuit of the single chip microcomputer is designed.This design uses 5v dc voltage.To guarantee the quality of power supply in the process of actual use, too much interference shouldn't be used. So filter circuit should be added to filter the clutter in the power .After acquisition of the analog from the sensor,the single chip of the monitoring point transforms the collected analogue to the corresponding gas concentration and air humidity value by reading the number of the AD register, and then some corresponding formula transformation.Single chip then packs the collected data, waiting for the instruction of the main unit. Monitoring point will transmit the packed data to the master station after receiving the command of sending data.MCU of the testing point will process the received nformation from the sensor and then transmit it to the master station via RS - 485 .After receiving the data,the main unit transmits it to the upper computer via RS232 and displays it through the kingview software in the upper computer.[3]

The operating principle of the gas concentration sensor MJC4/3.0 L in the monitoring device is the catalytic combustion effect.[4]Detecting element and compensating element become two arms of a bridge. When faced with combustible gas,resistance of the detecting element increases, bridge circuit output voltage variation, and the variable voltage varies with gas concentration increases. workers should be on-site investigation, avoid the accident when see voltage exceed ratings .

The humidity sensor HS1101 of the test system is mainly used for the detection of underground air humidity. HS1101 is a capacity cell, its capacitance increases with the increase of the measured air humidity. [5]Workers should be on-site investigation when see the capacity increases to a certain degree.The overall system design is shown in figure 1.

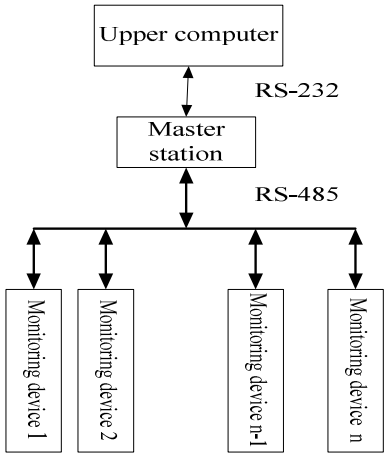

Figure 1: The system overall design

Table 1: Packet structure

start bit	A node	Humidity value	Calibration	check bit	stop bit

2. Sensor of the detection device

Sensors used in this system are the gas concentration sensor and the humidity sensor. They have good performance in measurement accuracy, corresponding speed, and pressure range.Here are the design of the sensor and the two chips were introduced.

1) **Gas concentration sensor**

The working principle of the catalytic element --MJC4/3.0 L is the catalytic combustion effect. Detecting element and the compensating element matching the two bridge arm of a bridge.

The detecting element resistance increases, when faced with gas combustible and the bridge circuit output voltage changes, the variable voltage varies with gas concentration increases. Its features are 1) bridge circuit output voltage is linear; 2) fast response; 3) has a good repeatability, selective; 4) components work stable and reliable; 5) resistance to H2S poisoning technical indicators.

2) **Humidity sensor**

Humidity sensor HS1101 has the following marked characteristics: 1) full interchangeability, does not need correction in a standard environment; 2) Long time fast dehumidifying under saturated 3) can be automated welding, including wave or water; 4) high reliability and stability for a long time; 5) patent solid polymer structure; 6) can be used in linear output voltage or frequency circuit; 7) rapid response time.

When the relative humidity is between 0% and 100% ,capacitance changed from 162 pF to 200 pF and the error is not greater than ±2% RH, response time is less than 5 s;temperature system is 0.04 pF /℃ . The accuracy of the humidity sensor is relatively high.

3. RS-485

RS-485 is a serial data communication, using two-way half-duplex communication protocols, its interface uses a combination of balance drive and the differential receiver ,it has a strong ability of common-mode interference, that is, good resistance to noise.

Software addressing is used in the RS - 485 . After the system is running, to make sure the RS-485 in each monitoring device has a unique address label,software addressing should be used.

When addressing for software, monitoring device can also save the host unit address, so monitoring device can communicate directly with the main unit point to point.

The main unit transmits data to the monitoring unit in the form of broadcast communication.Each monitoring device receives a packet.The monitoring will make some corresponding processing to the data when the received destination address matches its own. Packet structure is shown in table 1.

Due to this design contains multiple monitoring stations,if not controlled in actual use , there will be multiple monitoring points sending data at the same time , the correctness of the data transmission will be greatly reduced.

In order to solve this problem, this design uses the rotation machine to control the monitoring data transmission. For example, when the main unit need read the data of the monitoring stations 1, the main unit will send a read command to the whole network.

Each monitoring stations in the network will receive the read instructions, and then extract the address in it , if matching and the instruction is correct, then the corresponding monitoring will send the processed data to the main unit.

This mechanism has largely reduced the bit error rate in the process of communication, so as to improve the communication quality.

4. PC communication

The main unit receives data from various monitoring devices through RS485 bus and uses the single-chip microcomputer for data processing.

Data will be sent to the PC through the RS485 serial port after processing. The data will be displayed on the kingview software platform.

The software will number each monitoring point to make the display clear and intuitive.Even the monitoring point can check any historical record of the monitoring points.[6]

5. Summarize

The humidity of the gas concentration sensor designed in this paper adopts 1-wire bus specification, this makes the SCM read humidity and gas concentration signal via a data line. RS - 485 communication is used.To ensure safe and reliable in data transmission, no packet will be lost in the process of short distance communication.

E-mail: xieyehai@gmail.com

Keywords: ROV, adaptive, backsteeping, trajectory control

Abstract. In order to deal with the model uncertainties of ROV (remotely operated vehicles) caused by current disturbances, umbilical cable and robotic manipulators, an adaptive backstepping controller and an adaptive PD controller are applied to control the ROV. The adaptive backstepping controller is used to control the horizontal motion, and the adaptive PD controller is applied to control the Vertical motion. Finally, the method is verified effective by the computer simulation.

Introduction

There are various categories of unmanned underwater vehicles. The most often used underwater vehicle is a remotely operated vehicle (ROV) [1~8]. The ROV is usually connected to a surface ship by a tether, which all communication is wired through. Drag from the tether influences vehicle's motion and may represent significant disturbances and energy loss.

Some approaches have been studied to solve above challenges. In [1], the sliding variable structure control method is proposed to realize high precision trajectory control of ROV. An adaptive PID controller is designed to deal with the disturbances by ROV manipulators in [2]. The adaptive backstepping control was firstly developed to deal with model uncertainties of ROV [3].

The backstepping controller is designed to realize trajectory control for AUV under ocean current disturbance [11].

In this paper, in order to deal with the effect of ROV by environment disturbances, an adaptive backstepping controller and an adaptive PD controller are applied to control the ROV. The adaptive backstepping controller is used to control the horizontal motion of ROV, and the adaptive PD controller is applied to control the Vertical motion. Finally, the method is verified effective by the computer simulation.

ROV Model

The highly nonlinear, time-varying dynamic behavior of ROV continually changes the parameters of the system model [6~8]. The 6 DOF ROV equations of motion can be divided into the horizontal motion (surge, sway, yaw) and Vertical motion(pitch, heave).

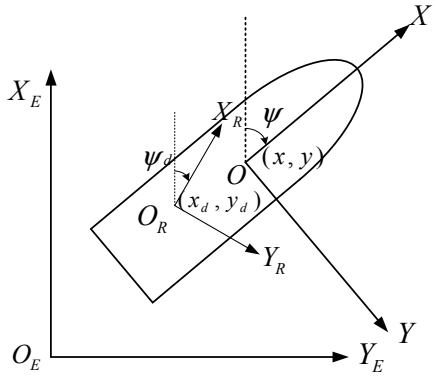

Fig. 1: Earth-fixed, reference-parallel and body-fixed frame

In ROV systems, the motions and state variables of the control system are defined and measured with respect to some reference frames or coordinate systems as shown in Figure. 1. The Earth-fixed reference frame is denoted as the $O_E - X_E Y_E Z_E$, the body frame is $O - XYZ$ see [1].

The horizontal model of ROV. The horizontal model of ROV in the frame can takes the form:

$$\begin{cases} \dot{\boldsymbol{\eta}}_1 = \boldsymbol{R}_1(\psi)\boldsymbol{v}_1 \\ \boldsymbol{M}_1\dot{\boldsymbol{v}}_1 + \boldsymbol{D}_1\boldsymbol{v}_1 = \boldsymbol{\tau}_1 + \boldsymbol{R}_1^{\mathrm{T}}(\psi)\boldsymbol{e}_1 \end{cases} \tag{1}$$

The state vector $\boldsymbol{\eta}_1 = [x, y, \psi]^{\mathrm{T}}$ is the position of the ship given in an inertial frame, $\boldsymbol{v}_1 = [u, v, r]^{\mathrm{T}}$ is the velocity vector in body frame $O-XYZ$.; $\boldsymbol{\tau}_1 = [\tau_{\mathrm{x}}, \tau_{\mathrm{y}}, \tau_{\psi}]^{\mathrm{T}}$ is the control vector consisting of forces and moments produced by the thruster system; $\boldsymbol{b}_1 \in \boldsymbol{R}^{3\times 1}$ is environmental disturbance. $\boldsymbol{M}_1$ is system inertia matrix including added mass; $\boldsymbol{D}_1$ is damping matrix:

$$\boldsymbol{M}_1 = \begin{bmatrix} m - X_{\dot{\mathrm{u}}} & 0 & 0 \\ 0 & m - Y_{\dot{\mathrm{v}}} & mx_G - Y_{\dot{\mathrm{r}}} \\ 0 & mx_G - N_{\dot{\mathrm{v}}} & I_z - N_{\dot{\mathrm{r}}} \end{bmatrix}, \quad \boldsymbol{D}_1 = \begin{bmatrix} -X_{\mathrm{u}} & 0 & 0 \\ 0 & -Y_{\mathrm{v}} & -Y_{\mathrm{r}} \\ 0 & -N_{\mathrm{v}} & -N_{\mathrm{r}} \end{bmatrix}$$

X_{u}, $X_{\dot{\mathrm{u}}}$, Y_{v}, $Y_{\dot{\mathrm{v}}}$, Y_{r}, $Y_{\dot{\mathrm{r}}}$, N_{v}, $N_{\dot{\mathrm{v}}}$, N_{r}, $N_{\dot{\mathrm{r}}}$, I_z is hydrodynamic coefficients, x_G is the surge coordinates to the center of gravity with respect to the point O in the body-fixed reference frame. $\boldsymbol{R}_1(\psi)$ is the transformation matrix:

$$\boldsymbol{R}_1(\psi) = \begin{bmatrix} \cos\psi & -\sin\psi & 0 \\ \sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

The Vertical model of ROV. If the rolling model is assumed to be negligible, this model reduces to the vertical model:

$$\begin{cases} \dot{\boldsymbol{\eta}}_2 = \boldsymbol{R}_2\boldsymbol{v}_2 \\ \boldsymbol{M}_2\dot{\boldsymbol{v}}_2 + \boldsymbol{D}_2\boldsymbol{v}_2 = \boldsymbol{\tau}_2 + \boldsymbol{R}_2^{\mathrm{T}}\boldsymbol{e}_2 \end{cases} \tag{2}$$

$\boldsymbol{\eta}_2 = [z, \theta]^{\mathrm{T}}$ is the depth and pitch angle of the ship given in an inertial frame; $\boldsymbol{v}_2 = [w, q]^{\mathrm{T}}$ is the heave vector and pitch angle vector in body frame $O-XYZ$; $\boldsymbol{\tau}_2$ is the control vector consisting of forces and moments produced by the thruster system; $\boldsymbol{b}_2 \in \boldsymbol{R}^{2\times 1}$ is environmental disturbance. $\boldsymbol{M}_2$ is system inertia matrix including added mass; $\boldsymbol{D}_2$ is damping matrix.:

$$\boldsymbol{M}_2 = \begin{bmatrix} m - Z_{\dot{w}} & -mx_G - Z_{\dot{q}} \\ -mx_G - M_{\dot{w}} & I_y - M_{\dot{q}} \end{bmatrix}, \quad \boldsymbol{D}_2 = \begin{bmatrix} Z_w & Z_q \\ M_w & M_q \end{bmatrix}$$

I_y is the moments of inertia about the; $Z_{\dot{w}}$, $Z_{\dot{q}}$, $M_{\dot{w}}$, $M_{\dot{q}}$ are add mass. The transformation matrix takes the form:

$$\boldsymbol{R}_2 = \begin{bmatrix} \cos(\theta) & 0 \\ 0 & 1 \end{bmatrix}.$$

The controller of ROV

In order to deal with the model uncertainties of ROV (remotely operated vehicles) caused by current disturbances, umbilical cable and robotic manipulators, an adaptive backstepping controller and an adaptive PD controller are applied to control the ROV.

The adaptive backstepping controller of horizontal motion. In the past decade, the backstepping control design procedures have been proposed in the literature [3, 10]. This control technique is a systematic and recursive design methodology for nonlinear systems, which offers a choice to accommodate the unmodeled nonlinear effects and parameter uncertainties. The idea of backstepping design is to select recursively some appropriate functions of state variables as pseudo-control inputs for lower dimension subsystems of the overall system. Each backstepping stage results in a new pseudo-control design, expressed in terms of the pseudo-control design from preceding design stages. The procedure terminates a feedback design for the true control input which achieves the original design objective by virtue of a final Lyapunov function which is formed by summing the Lyapunov functions associated with each individual design stage.

In this section, an adaptive backstepping controller is designed to controller surge, sway and yaw motion.

First, we defined the tracking error:

$$z_1 = \boldsymbol{\eta}_1 - \boldsymbol{\eta}_{1d} \tag{3}$$

$\boldsymbol{\eta}_{1d}$ is the desired state in an inertial frame.

A first Lyapunov function for the first error variable is defined as:

$$V_1 = \frac{1}{2} z_1^{\mathrm{T}} \boldsymbol{P}_1 z_1 \tag{4}$$

$\boldsymbol{P}_1 > 0$， $\boldsymbol{P}_1 = \mathrm{diag}\{p_{11}, p_{22}, p_{33}\}$ is a positive definite diagonal matrix.

The derivative of (4) is obtained as:

$$\dot{V}_1 = z_1^{\mathrm{T}} \boldsymbol{P}_1 \left(\boldsymbol{R}_1 \boldsymbol{v}_1 - \dot{\boldsymbol{\eta}}_{1d} \right) = -z_1^{\mathrm{T}} \boldsymbol{C}_1 z_1 + z_1^{\mathrm{T}} z_2 \tag{5}$$

With $\boldsymbol{C}_1 > 0$, $\boldsymbol{C}_1 = \mathrm{diag}\{c_{11}, c_{22}, c_{33}\}$ withis a positive definite diagonal matrix. The second error variable z_2 is given as:

$$z_2 = \boldsymbol{C}_1 z_1 + \boldsymbol{P}_1 \left(\boldsymbol{R}_1 \boldsymbol{v}_1 - \dot{\boldsymbol{\eta}}_{1d} \right) \tag{6}$$

The estimate of the vector $\hat{\boldsymbol{e}}_1$ is denoted, and the parameter estimation error is written.

$$\tilde{\boldsymbol{e}}_1 = \hat{\boldsymbol{e}}_1 - \boldsymbol{e}_1 \tag{7}$$

The candidate Lyapunov function in this case is defined as:

$$V_2 = V_1 + \frac{1}{2} z_2^{\mathrm{T}} \boldsymbol{P}_2 z_2 + \frac{1}{2} \tilde{\boldsymbol{e}}_1^{\mathrm{T}} \boldsymbol{\Gamma}^{-1} \tilde{\boldsymbol{e}}_1 > 0 \tag{8}$$

where $\boldsymbol{P}_2 > 0$, $\boldsymbol{P}_2 = \mathrm{diag}\{f_{11}, f_{22}, f_{33}\}$ and $\boldsymbol{\Gamma}_2 > 0$, $\boldsymbol{\Gamma} = \mathrm{diag}\{\gamma_{11}, \gamma_{22}, \gamma_{33}\}$ are a positive definite diagonal matrix.

The derivative of (8) is obtained as:

$$\dot{V}_2 = -z_1^{T} \boldsymbol{C}_1 z_1 + \frac{1}{2} \tilde{\boldsymbol{e}}_1^{\mathrm{T}} \boldsymbol{\Gamma}^{-1} \dot{\hat{\boldsymbol{e}}}_1 + z_2^{\mathrm{T}} \boldsymbol{P}_2 \boldsymbol{P}_1 \boldsymbol{R} \boldsymbol{M}_1^{-1} \left(\boldsymbol{\tau}_1 - \boldsymbol{D}_1 \boldsymbol{v}_1 + \boldsymbol{R}_1^{\mathrm{T}} \boldsymbol{e}_1 \right) + z_2^{\mathrm{T}} \left(z_1 + \boldsymbol{P}_2 \boldsymbol{C}_1 \dot{z}_1 + \boldsymbol{P}_2 \boldsymbol{P}_1 \left(\dot{\boldsymbol{R}}_1 \boldsymbol{v}_1 - \ddot{\boldsymbol{\eta}}_{1d} \right) \right) \tag{9}$$

Collecting terms in $\tilde{e}_1$, yields:

$$\begin{aligned} \dot{V}_2 &= \tilde{\boldsymbol{e}}_1^{\mathrm{T}} \boldsymbol{\Gamma}^{-1} \left(\dot{\hat{\boldsymbol{e}}}_1 - \boldsymbol{\Gamma} \boldsymbol{R}_1 \boldsymbol{M}_1^{-\mathrm{T}} \boldsymbol{R}_1^{\mathrm{T}} \boldsymbol{P}_1 \boldsymbol{P}_2 z_2 \right) + z_2^{\mathrm{T}} \left(z_1 + \boldsymbol{P}_2 \boldsymbol{C}_1 \dot{z}_1 + \boldsymbol{P}_2 \boldsymbol{P}_1 \left(\dot{\boldsymbol{R}}_1 \boldsymbol{v}_1 - \ddot{\boldsymbol{\eta}}_{1d} \right) \right) \\ &+ z_2^{\mathrm{T}} \boldsymbol{P}_2 \boldsymbol{P}_1 \boldsymbol{R}_1 \boldsymbol{M}_1^{-1} \left(\boldsymbol{\tau}_1 - \boldsymbol{D}_1 \boldsymbol{v}_1 + \boldsymbol{R}_1^{\mathrm{T}} \hat{\boldsymbol{e}}_1 \right) - z_1^{\mathrm{T}} \boldsymbol{C}_1 z_1 \end{aligned} \tag{10}$$

The parameter adaptation law:

$$\dot{\hat{\boldsymbol{e}}}_1 = \boldsymbol{\Gamma} \boldsymbol{R}_1 \boldsymbol{M}_1^{-\mathrm{T}} \boldsymbol{R}_1^{\mathrm{T}} \boldsymbol{P}_1 \boldsymbol{P}_2 z_2 \tag{11}$$

The control force

$$\boldsymbol{\tau}_1 = \boldsymbol{D}_1 \boldsymbol{v}_1 - \boldsymbol{R}_1^{\mathrm{T}} \hat{\boldsymbol{e}}_1 - \boldsymbol{M}_1 \boldsymbol{R}_1^{\mathrm{T}} \left(\dot{\boldsymbol{R}}_1 \boldsymbol{v}_1 - \ddot{\boldsymbol{\eta}}_{1d} \right) - \boldsymbol{M}_1 \boldsymbol{R}_1^{\mathrm{T}} \boldsymbol{P}_1^{-1} \left(\boldsymbol{C}_1 \dot{z}_1 + \boldsymbol{P}_2^{-1} \left(z_1 + \boldsymbol{C}_2 \boldsymbol{Z}_2 \right) \right) \tag{12}$$

$\boldsymbol{C}_2 > 0$, $\boldsymbol{C}_2 = \mathrm{diag}\{\lambda_{11}, \lambda_{22}, \lambda_{33}\}$ is a positive definite diagonal matrix.

Finally yields $\dot{V}_2$ non-positive by

$$\dot{V}_2 = -z_1^{\mathrm{T}} \boldsymbol{C}_1 z_1 - z_2^{\mathrm{T}} \boldsymbol{C}_2 \boldsymbol{Z}_2 \le 0 \tag{13}$$

Thus the system is globally asymptotically stable, that is to say that z_1 converge to 0.

The adaptive PD controller of Vertical motion. Vertical motion of ROV include the heave motion and the pitch motion.The robustness of the 6 DOF adaptive PD controller is illustrate by [2]. In this paper, a 6 DOF adaptive PD controller is paoposed:

$$\begin{cases} \dot{\hat{\boldsymbol{e}}}_2 = -\boldsymbol{\Gamma} \boldsymbol{\Phi}^{\mathrm{T}} (\boldsymbol{\eta}_2) \left(\dot{\boldsymbol{\eta}}_2 + \dfrac{\varepsilon_0}{1 + a \left\| \tilde{\boldsymbol{\eta}}_2 \right\|} \tilde{\boldsymbol{\eta}}_2 \right) \\ \boldsymbol{\tau}_2 = -\boldsymbol{R}_2^{\mathrm{T}} \boldsymbol{K}_P \tilde{\boldsymbol{\eta}}_2 - \boldsymbol{R}_2^{\mathrm{T}} \boldsymbol{K}_D \dot{\boldsymbol{\eta}}_2 + \boldsymbol{R}_2^{\mathrm{T}} \boldsymbol{\Phi} (\boldsymbol{\eta}_2) \hat{\boldsymbol{e}}_2 \end{cases} \tag{14}$$

$\tilde{\boldsymbol{\eta}}_2 = \boldsymbol{\eta}_2 - \boldsymbol{\eta}_{2d}$ is the position error, $\hat{\boldsymbol{e}}_2$ is the estimate environment force, $\boldsymbol{\eta}_{2d}$ is reference trajectory, $\boldsymbol{\Phi}^{\mathrm{T}} (\boldsymbol{\eta}_2)$ is the regression matrix, $\varepsilon_0 < 1$ and a are positive constants; $\boldsymbol{\Gamma} \in \boldsymbol{R}^{2\times 2}$， $\boldsymbol{K}_P \in \boldsymbol{R}^{2\times 2}$， $\boldsymbol{K}_D \in \boldsymbol{R}^{2\times 2}$ is a positive definite matrix.

Simulation Research

To demonstrate the performance of the proposed controller in this paper, the ROV called "Ukwiał" is used as case study, the ROV having 1.5 m long and having a propulsion system consisting of 6 thrusters. The following ROV model of dynamics has been used in the computer simulation:

$$\boldsymbol{M} = \mathrm{diag}\{\ 99.0,\ \ 108.5,\ \ 126.5,\ \ 8.2\ \ 32.9,\ \ 29.1\}$$

$$\boldsymbol{D}(\boldsymbol{v}) = \mathrm{diag}\{10.0,\ \ 0.0,\ \ 0.0,\ \ 0.223\ \ 1.918,\ \ 1.603\} + \mathrm{diag}\begin{Bmatrix} 227.18|u|, & 405.41|v|, & 478.03|w| \\ & 3.212|p|, & 14.002|q|, \quad 12.937|r| \end{Bmatrix}$$

$$\boldsymbol{C} = \begin{bmatrix} 0 & 0 & 0 & 0 & 26.0w & -28.0v \\ 0 & 0 & 0 & -26.0w & 0 & 18.5u \\ 0 & 0 & 0 & 28.0v & -18.5u & 0 \\ 0 & 26.0w & -28.0v & 0 & 5.9r & -6.8q \\ -26.0w & 0 & 18.5u & -5.9r & 0 & 1.3p \\ 28.0v & -18.5u & 0 & 6.8q & -1.3p & 0 \end{bmatrix} \quad \boldsymbol{g}(\boldsymbol{\eta}) = \begin{bmatrix} -17.0\sin(\theta) \\ 17.0\cos(\theta)\sin(\varphi) \\ 17.0\cos(\theta)\cos(\varphi) \\ -279.2\cos(\theta)\sin(\varphi) \\ -279.2\left(\sin(\theta)+\cos(\theta)\cos(\varphi)\right) \\ 0 \end{bmatrix}$$

Simulation experiments were made for tracking control under interaction of sea current disturbance (speed 0.5 m/s, direction 30^0). The matrix $[30,-70,30,0,0,0]$ is used as the by umbilical cable and robotic manipulators. The vehicle was assumed to follow the trajectory beginning from position and orientation:

$$\begin{cases} x = \dfrac{3}{500s+1} \\ y = \dfrac{10}{500s+1} \\ z = 10 \\ \theta = 0^\circ \\ \psi = 50^\circ \end{cases},$$

the vessel controller gains are shown in table 1 and table 2. The simulation curve shown in Figure 2 and Figure 3.

Table 1 The gains of adaptive backstepping controoler

Matrix	Diagonal element		
$\boldsymbol{\Gamma}$	2.6	2.0	2.4
$\boldsymbol{P}_1$	2.4	1.8	3.2
$\boldsymbol{P}_2$	2.9	1.5	4.9
$\boldsymbol{C}_1$	2.8	3.2	2.8
$\boldsymbol{C}_2$	2.4	3.3	4.3

Table 2 The gains of adaptive PD controller

Matrix	Diagonal element
$\boldsymbol{K}_p$	$\boldsymbol{M}\times 0.016$
$\boldsymbol{K}_d$	$\boldsymbol{M}\times 0.8$
$\boldsymbol{\Gamma}$	[2,0;0,1]
ε_0	0.6
a	2
$\boldsymbol{\Phi}$	[1,1;1,1]

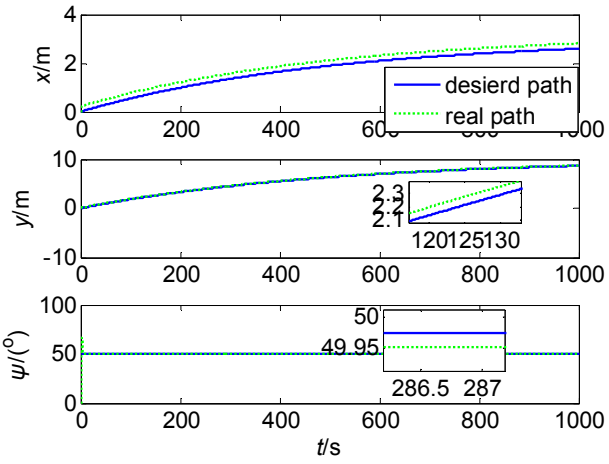

Figure 2 The simulation curve of adaptive backstepping controller

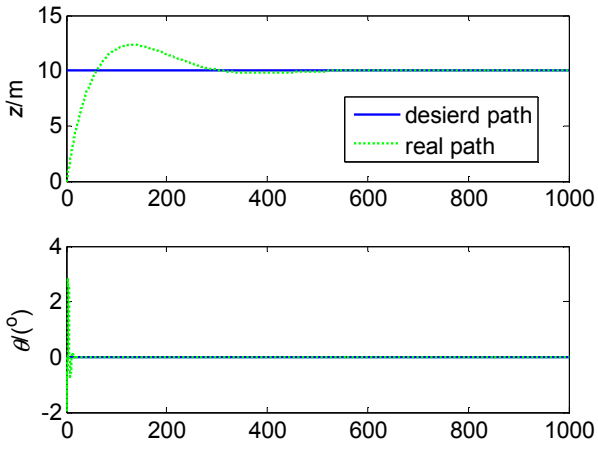

Figure 3 The simulation curve of adaptive PD controller

From Fig.2 and Fig.3, we can see that the adaptive backstepping controller and an adaptive PD controller output was smooth,meanwhile, the controller provid good dynamic response performance and small tracking error.

Conclusions

In this paper, the adaptive backstepping controller and an adaptive PD controller is proposed to deal with the model uncertainties of ROV, which is caused by current disturbances, umbilical cable and robotic manipulators.The simulation results show the proposed controller performs well with stability and robustness and can improve the accuracy of ROV.

Keywords: large power industrial control network; network security; data storm; data storm monitoring

Abstract. In the high power industrial control network, due to the large user base, the data traffic is plodding, the data formats are inconsistent, the network data storm is difficult to monitor. A kind of high power industrial control network data monitoring and control system is designed under non-uniform formats. The network node information collector is designed, the data is collected, and the data collection result is taken as the mathematical expectation, the mathematical expectation is trained. The problem of data flow storm statistics is solved. In the system, the format conversion function is added, data storm monitoring results is taken with the format conversion, and they are stored as text format. The monitoring program reads and displays the result, the difficulties brought by the format is not unified are solved. System test results show that the system can monitor the large power industrial control network data storm, the monitoring result is precise, and it can make the formatting process fast. A size of the generated result file is 18.1%, of the original file, and can fully reflect the network data storm characteristics, the effect is perfect.

Introduction

With the deepening development of network technology and digital technology, the large power industrial control network is getting more and more important in electric power plant, and the military system. The large power industrial control network is widely applied in different areas. The large power industrial control network application is developing rapidly, and the technology us upgrading constantly, because the user base is too large, the number of computers is large. The network data storm data is very complex, so the monitoring crisis is increasing gradually[1].

In the high power industrial control network, due to the large user base, the data traffic is plodding, the data formats are inconsistent, the network data storm is difficult to monitor. A kind of high power industrial control network data monitoring and control system is designed under non-uniform formats[2]. The network node information collector is designed, the data is collected, and the data collection result is taken as the mathematical expectation, the mathematical expectation is trained. The problem of data flow storm statistics is solved. In the system, the format conversion function is added[3], data storm monitoring results is taken with the format conversion, and they are stored as text format. The monitoring program reads and displays the result, the difficulties brought by the format is not unified are solved. System test results show that the system can monitor the large power industrial control network data storm, the monitoring result is precise, and it can make the formatting process fast. The simulation result shows that the new method has good performance in application.

System design principle

The design of system module mainly includes 2 parts: coordination monitoring module, and the system operation module, the system module structure is shown in Figure 1. The main functions of the system include:

Figure 1 System module structure

(1) Monitoring new data storm nodes continuously in real-time, each of the data information are collected with sub module, and it is allocated with the only identification code in gather module distribution.

(2) Waiting for the feedback data of storm nodes monitoring results, the self organization method is adopted to transmit each node monitoring module data, upload to the coordinator module storage unit.

(3) In the coordinator module, automatic centralized data collected by the storm monitoring system is transmitted to the control center, in the control center, the monitoring algorithm is used to analyze the data storm data in real time, the network can be used to monitor real-time network data storm and control the relevant data sending program[4].

The flow chart of network monitoring module is shown in Figure 2, the main functions include:

(1) Initialization module, the self-organization mode is taken for adding the nodes to the network storm monitoring area;

(2) Obtain sole identification code of data storm from the coordinator node, and monitoring network control information.

(3) Acquisition network data storm information data timing, and data storm monitoring algorithm is designed to analyze the data, the data is transmitted to the coordinator node.

(4) Executes operation step (3), until leaving the monitoring area network.

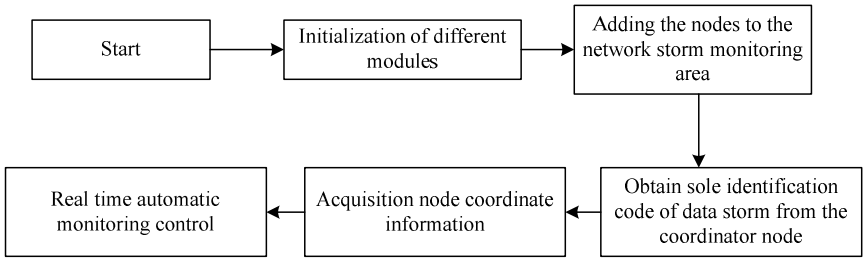

Figure 2 Flow chart of monitoring system design flow chart

Monitoring system design

A.Design of data acquisition module of network node data storm

This function module is affected by the underlying network greatly, and the large power industrial control network should be controlled[5], the network data storm should be managed, we must maintain the real-time monitoring of large power industrial control network data, to determine the statistical characteristics of the data storm, the statistical characteristics are calculated. The information collector is used to receive the data storm information, so the structure diagram of the module is shown in Figure 3.

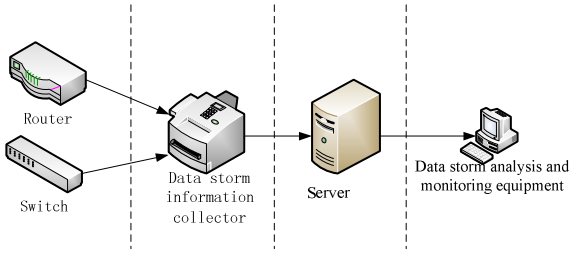

Figure 3 Structure diagram of data storm monitoring module

In the large power industrial control network system, the network switch and router are used to analyzed the statistics of storm data, the result is transmitted to the information collector, and the information collector is summarized to the server, and then passed to the data analysis and monitoring equipment to monitor the storm, this function is implemented on the Windows platform, data statistics calculation and storm display can be realized with this method, and according to the data statistics result, the monitoring can be realized, and the VC++6.0 is used for the program realization, including data processing module and data statistics module of the storm.

The information collector is the core module of monitoring nodes, the to complete the analysis of the network interface data acquisition, data statistics and storm monitoring function, in the data analysis process, the network intrusion feature can be detected, the process is shown in Figure 4.

The machine IP address is realized by the C++ function, gethostname function and gethostbyname function are designed, at the same time, the cache setting is obtained, the socket and a port number are created, and the thread is started. The AIP function of Microsoft is used to count the IP data, and the statistics information of network data storm can be calculated, according to monitoring changes in network performance, the network data storm trend can be predicted.

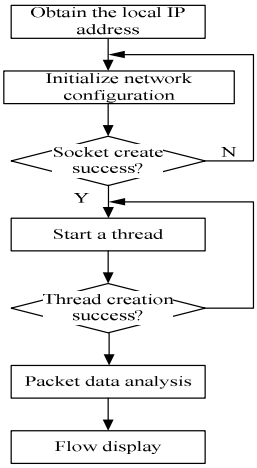

Figure 4 Monitoring module design process

B.Network data storm flow module design

In order to monitor the network data storm, the network flow should be flowed effectively, for any kind of shunt method, the basic functions of the network data storm is important, it is divided into stream files, and the process will include the source IP address, source port, destination IP address, destination port and protocol, etc. form a complete stream file. The mechanism of this process is relatively simple, but with the rapid development of P2P network, data network storm become extremely complex, data redundancy is increasing, and it should be removed. How to flow the massive data with several GB is difficult, and the process research is important. We should realize the rapid flow of network data the storm in the Windows environment.

In the large power industrial control network, the user most contains the engineers and workers at the grass-roots level, the data storm whereabouts is mainly plant room and staff accommodation, the user is divided in accordance with the regional division, in each area, the information collector is installed. The data is captured in three hour, the compressed data storm is crated with the file, and the size is 10GB. After the conversion trace, the original pcap file is more than 3 times with conversion, and the data packet task is huge. In the process of storm tracks, the data storm test and comprehensive are balanced in efficiency.

Before the bypass flow, the data storm trace files are extracted, based on network data storm, the network data storm will have the same elements which are similar to class files, and these elements are referred as source IP address, source port, destination IP address, destination port and protocol as above. For testing the network data storm in different period data, the protocol is analyzed, the results is expressed in table 1.

Table 1. Document classification of data collection protocol

	UDP	TCP	IPv6	Other	Total number
1	67.1%	30.1%	1.0%	1.8%	1814391
2	67.3%	30.1%	0.9%	1.7%	258315
3	67.1%	30.3%	0.3%	1.6%	539341

According to the statistics results, the TCP protocol and UDP protocol files are taken about more than 97%, and other data storm file types and the ratio is no more than 3%, there exists only a small amount of IP protocol and IPv6 protocol file. So the protocol type rare special data package is ignored, so as to accelerate the speed of flow analysis. Because the file of data trace is large, and it occupies more space in memory, the random sampling of the data file is captured in export mirror at the storm data, in different periods, the parallel and serial operations are taken, and the test time is five minutes and ten minutes. The process is shown in Figure 5.

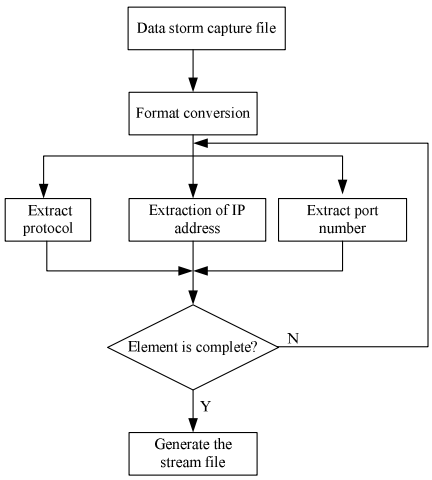

Figure 5 Network data distribution process

Test result and analysis

In the simulation, the local area network of a college is taken as the example, and modules are tested, the information collector is designed to collect all the storm of campus network in 60 seconds, and the captured data set is saved as pcap format, the format conversion is taken to generate the TXT text file. The data pretreatment is taken, and the GA-BP neural network with multi input multi output (MIMO) is used for training, the training expected value is provided by the stream file generated in advance. After generating the TXT text file, the result is shown in interface as display, by the use of data storm, the scheduling is obtained to facilitate the administrator. The system structure is shown in Figure 6.

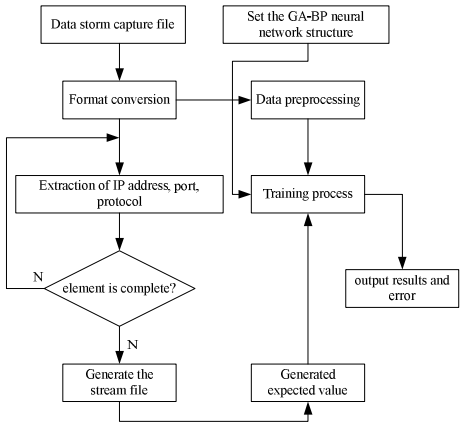

Figure 6. Structure of the overall system

The distribution results of network data storm is shown in Table 2, we can conclude that, in single threaded mode, just a few minutes of continuous time, it also needs 2 hours or more time for distribution, and it affect real time performance of storm monitoring system. The new BP neural network algorithm based on GA, the processing time is reduced.

Table 2. Storm distribution result record

	Data length	Distribution time	File size
1	60s	1459s	1.28GB
2	120s	3091s	2.11GB
3	300s	7851s	5.68GB

The BP neural network algorithm based on GA, the algorithm of the initial file is set, and the data pre-processing storm file, and set the BP neural network structure, the expected value according to the statistical results average worth, and the split files display division of the regional network evolution, to display the shunt factory of each room and staff accommodation data storm. The network storm data is monitored for 60 seconds, and the monitoring results are expressed as follows: Data length of data storm is 80s, and the training time is 24781s, the result display time is

143s, and the size of TXT file is 232MB, the success rate of abnormal data storm monitoring is 89%. It shows that the new method has better monitoring performance in application.

Conclusion

In this paper, a big power network data storm monitoring system is designed under non uniform format, the distribution time consumption is reduced, and the monitoring results are streamlined and display, the data duration reduced to 80 seconds, and the TXT format can be saved safely, the size is reduced to 232MB, and it is 18.1% of original TXT, the volume occupied effect is reduced effectively, and the data availability is good, the system has certain practical application in prospect.

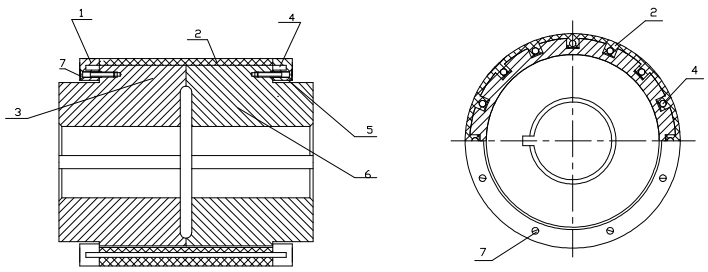
Keywords: elastic, gear coupling, design, finite element analysis

Abstract： This paper introduces a new type of elastic gear coupling structure, and gives the calculating strength formula and related material of the parts, establishes the three-dimensional model, simulates the nonlinear elastic gear ring, gets the analysis of the distribution of strain and stress in the ANSYS software, verify the strength condition.

0 Introductions

Couplings are usually used to connect two axis and transfer movement and power. According to the difference of compensating the migration ability, couplings can be divided into two categories, named rigid coupling and flexible coupling. Flexible couplings are divided into non elastic element coupling and flexible coupling. Gear coupling is a kind of no elastic coupling which connect the two half parts using internal and external gear meshing. It can transfer large torque, high speed, with reliable work, low requirement on installation accuracy, but the structure is complicated, with difficult manufactory, high cost [1]. We design a new type of elastic gear coupling, try to keep the advantages of gear coupling that can transfer large torque, and has the feature of shock absorption.

1 The structure of elastic gear coupling



1 Left circlip
2 elastic gear ring
3 left half coupling
4 strengthen shaft
5 right circlip
6 right half coupling
7 screws

Fig. 1 The sketch of the elastic gear coupling

The elastic gear coupling's structure is shown in Figure 1, the two half couplings are connected through a elastic gear ring 2, each tooth of the ring embedded with strengthening shafts 4, which is inserted into the hole of left circlip 1 and right circlip 5 [2]. Aim at the following advantages: obtain the stability of transmission, without rigid impact and noise; can compensate the larger axial displacement, small radial and angular displacement; no need of lubrication.

2 The strength of elastic gear coupling

2.1 Working torque

According to Mechanical Design Manual, the working torque is: $Tc=K_wKK_zK_tT$ (1)

Where T is the nominal torque; K_w is the power coefficient; K is condition coefficient; K_z is starting condition coefficient; K_t is the temperature coefficient [3].

2.2 The size and material determination of strengthen shaft

According to the "mechanical design manual", referring to the elastic pin sleeve coupling size relationship, the distribution diameter of strengthen shaft is: $D=(15\sim16.5)\sqrt[3]{Tc}$ (2)

The shear force of each strengthening shafts Fs:

$$Fs = \frac{2Tc}{\mathrm{D}n} \times \varphi \quad (3)$$

Where Dn is the distribution diameter of strengthen shafts; n is strengthening shafts' number; φ is uneven coefficient of each tooth.

According to mechanics of materials, calculate the shear strength condition of strengthen shafts:

$$\tau_{\max} = \frac{4}{3} \frac{4Fs}{\pi \mathrm{D}^2} \le [\tau] \quad (4)$$

According to the "mechanical design manual", refer to the elastic pin sleeve coupling bending strength condition, calculate the bending strength condition of strengthen shafts:

$$\sigma_{\max} = \frac{10Tc(l+2c)}{0.8D\mathrm{n}d^3} \le [\sigma] \quad (5)$$

Where l is the width of the elastic ring; C is the clearance of two half couplings' ends; D is the distribution diameter of strengthen shafts; d is the diameter of strengthen shafts; $[\sigma]$ is the allowable bending stress of strengthen shafts , and generally $[\sigma]$=（0.4～0.5）σ_s.

2.3 Strength check of elastic ring

Calculate the tooth surface pressure:

$$\mathrm{P} = \frac{2Tc}{nhlD} \le [p_p] \quad (6)$$

Where h is height of tooth; l is width of tooth ring.

3 The design example of the elastic gear coupling

The couplings are used for the plate chain conveyor, the requirements are: working torque is 500N.m, transmission power is 3.5kW, and compensating capacity shall reach or better than the flange coupling and hydraulic coupling.

In order to reduce manufacturing difficulty and cost, consider using a standard synchronous toothed belt with the strengthening shafts. According to the synchronous toothed belt main dimensions and parameters in national standard, select XH type synchronous belt, as an example, carries on the design calculation. According to the formula (1), (2), (3), calculate the shear force of each strengthening shafts Fs:

$$\mathrm{Fs} = \frac{2Tc}{\mathrm{D}n} \times \varphi \frac{2 \times 600 \times 10^3}{130 \times 20 \times 0.7} = 659.25N$$

According to the formula (4), calculate the shear strength condition of strengthen shafts:

$$\tau = \frac{4}{3} \frac{4Fs}{\pi \mathrm{D}^2} = \frac{4}{3} \times \frac{4 \times 659.25}{3.14 \times 141.56^2} = 0.056\mathrm{Mpa}$$

It is found that the strengthening shaft shear capacity was enough, the shear stress is much less than the allowable stress of metallic material.

According to the formula (5), calculate the bending strength condition of strengthen shafts:

$$\sigma = \frac{10Tc(l+2c)}{0.8D\mathrm{n}d^3} = \frac{10 \times 600 \times 10^3 \times (101.6 + 2 \times 2)}{0.8 \times 130 \times 20 \times 7^3} = 888\mathrm{Mpa}$$

Check the "Material Handbook" to meet the requirements of the material, can select GCr15 bearing steel, or spring alloy steel. Geometry may refer to the material and size of needle for roller bearing.

According to the formula (6), calculate the surface pressure of elastic ring's teeth:

$$p = \frac{2Tc}{nhlD} = \frac{2 \times 600 \times 10^3}{20 \times 6.35 \times 101.5 \times 130} = 0.72\mathrm{M}pa$$

General rubber allowable pressure $[p_p]$ =2~2.5Mpa, so extrusion strength with the rubber ring's teeth was enough.

4 Modeling and analysis of elastic gear coupling

Establish the coupling model shown in figure 2 in the Pro/E software. And transfer the model to the finite element analysis software ANSYS to do mechanical analysis.

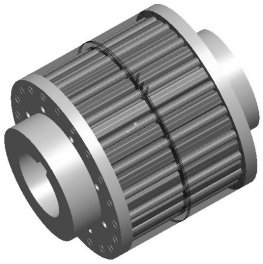


Fig.2 Elastic gear coupling model

The elastic gear coupling ring is composed by rubber layer and the strengthening layer etc, in this analysis, the elastic ring is simplified to a single rubber material. In order to simplify the problem, this paper does not consider the influence of parts' clearance and centrifugal force. And consider that in the work process, two half couplings and ring are not isolated; the pre-tightening force of screw extrusion pressure is negligible. Based on these simplifications, to do the finite element analysis of the coupling [4]。

4.1 Setting of material properties

Engineering Data provides sample material data categorized into several libraries. Setting the material properties of two half couplings and the strengthening shafts to structure steel as system default material selection in engineering data.

For the nonlinear material properties, ANSYS software provides Hyperelastic Materials, such as Mooney-Rivlin model, Yeoh model, the Mooney-Rivlin model. Elastic ring's deformation is small in the normal working range, choose Mooney-Rivlin model [5][6] [7], we stretch into the rubber experimental uniaxial stress-strain data, shear stress- strain data. Stress-strain data curves as shown in Figure 3 and figure 4.

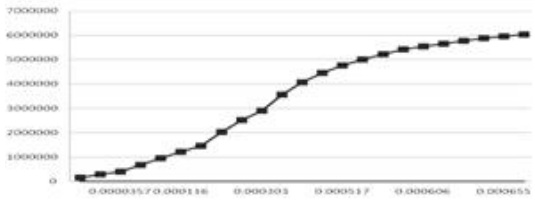

Fig.3 Uniaxial stress-strain curves

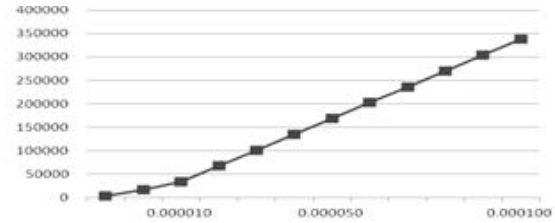

Fig.4 Shear stress-strain curves

4.2 Element type and mesh generation

Because the coupling is mainly solid element, SOLID185 Homogeneous Structural Solid Geometry with 8 nodes mesh the mode, the final element count is 62170, the node count is 312356.The finite element model of coupling is shown in figure 5.

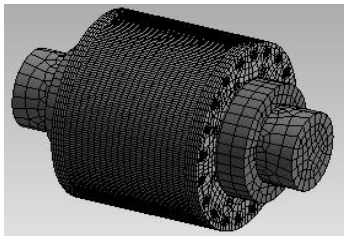

Fig. 5 The meshed finite element model in workbench

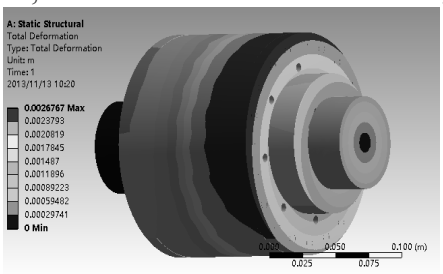
4.3 constraints and loadings

According to the actual stress of the coupling, creates constraints and loadings. Creates a fixed constraint on the left half shaft end; contact constraints on coupling shaft and key, two half couplings and shafts, two half couplings and ring etc.Add the torque of 500N.m on circumferential surface of the right half coupling, which is equivalent to the right coupling shaft as a driving shaft, the left as driven shaft [8].

4.4 Results and discussion

The model was calculated in ANSYS workbench, the total deformation, stress and strain distribution of model was shown in Figure 6; strain distribution of strengthening shafts which were key components was shown in Figure 7; stress distribution of strengthening shafts was shown in Figure 8; stress distribution of elastic ring was shown in Figure 9.



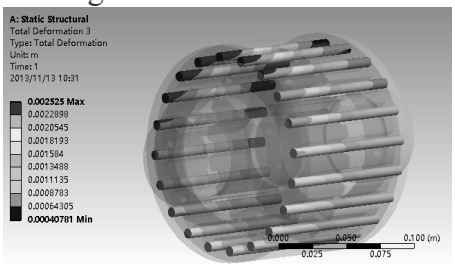


Fig. 6 The total deformation, stress and strain distribution of model

Fig. 7 Strain distribution of strengthening shafts

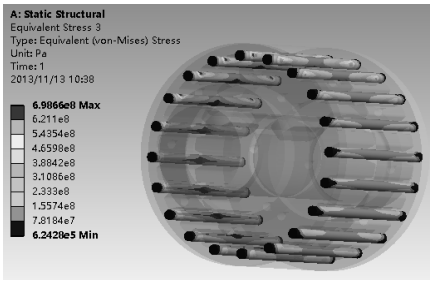

Fig. 8 Stress distribution of strengthening shafts **Fig. 9 Stress distribution of elastic ring**

5 Conclusions

Through the analysis, the maximum deformation occurs on the surface of elastic ring nearby the key connection, and on the strengthening shafts and the circlips. The maximum equivalent stress occurs on the key connection, and on the contact points of the strengthening shafts and the circlips, the maximum equivalent stress is 698.7Mpa. We come to conclusions that the strengthening shafts are

Key components for this elastic gear coupling in the simplified working environment, the stress of elastic gear ring mainly reduce the vibration affection on which of stress is less, the analysis results act in accordance with design results. According to the results of the analysis, design sizes of the model can be further optimized [9]

Keywords: Sub-synchronous Control Interaction; DFIG; test signal method; equivalent model;

Abstract. Large-scale wind turbine generators with power electronic converters that operate near series compensated transmission lines are susceptible to un-damped sub-synchronous oscillations. This sub-synchronous oscillation is called Sub-synchronous Control Interaction (SSCI). Based on PSCAD / EMTDC simulation platform the establishment of Double Fed Induction Generator(DFIG) equivalent inverter controlled sources and network model, and verify the correctness of the equivalent model. Analysis the impact of series compensation and rotor -side converter PI parameters characteristic of the SSCI based on test signal method and time-domain simulation method. The results show that increasing the degree of series compensation , inner gain constant increases and inner integral time decreases will help increase SSCI, outer ring of PI parameters has little effect on the SSCI .

Introduction

In recent years , wind power at home and abroad has been rapidly developed , by 2020 , China's total installed capacity of wind power will be more than 200 million kilowatts , where offshore wind power capacity has reached 30 million kilowatts, wind power generating capacity will reach 390 billion kwh . Wind power generating capacity in power generation will be accounted for more than 5% [1-2] . Because wind farms are mostly located in remote areas , far from the centers , to address the problem of large-scale wind power deliveries , series compensation technology has been widely used. However, compensation may induce sub-synchronous oscillation problems , impact safety of wind farms as well as outgoing and stable operation of the system [3-8].

According to the interaction of different objects , sub-synchronous oscillation of wind turbines have three types of problems , which are sub-synchronous resonance (SSR), referring to the interaction between wind turbine shaft and the fixed series compensation ; Sub-synchronous Torsional (SSTI), mainly refers interaction to between the role of wind turbine controller or an adjacent FACTS device controller and wind turbine shafting ; Sub-synchronous Control Interaction(SSCI), such is defined by the interaction of wind turbine controller with fixed series compensation triggered the SSO .

This article creates a detailed DFIG equivalent inverter controlled sources and network model, and equivalent to verify the correctness of the model simulation . Based on PSCAD / EMTDC simulation platform, combined with the time-domain simulation of complex torque coefficient method-test signal method to analyze the impact of series compensation control parameters of the transmission line and the rotor-side converter of SSCI , but also time-domain simulation method analyze the impact of these parameters on the SSCI .

System Model

DFIG sent power via the fixed line infinite series compensation system is shown in figure 1 . Induction generator using a single rigid model does not consider the effect of torsional vibration interaction. Induction generator parameters according to the literature [9] settings, as shown in Table

1 ; self-induction generator impedance parameters in Table 1's reference value are its' rated power and voltage.

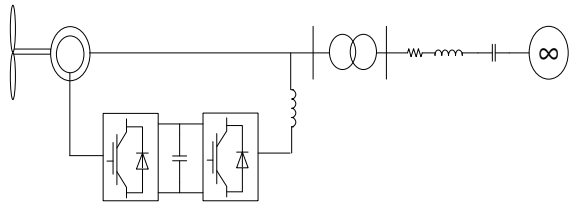

Fig.1 The schematic diagram of DFIG-based wind-power system

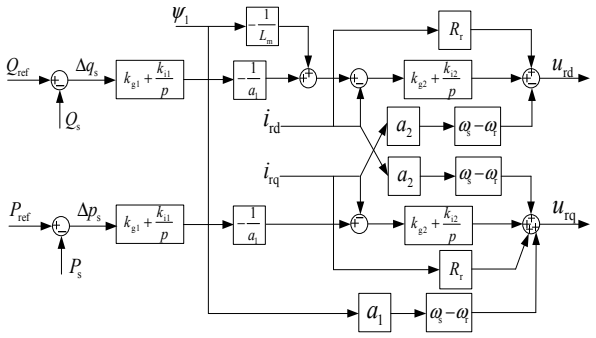

Fig.2 DFIG rotor -side converter control block

Tab.1 The parameters of the induction generator

parameters	Value
rated power	1.5MW
rated voltage	0.69kV
Grid frequency	50Hz
Stator leakage reactance	0.177p.u.
Rotor resistance	0.1p.u.
Rotor leakage reactance	0.116p.u.
Magnetizing reactance	4.68p.u.

Figure 2 is a DFIG rotor -side converter control system block diagram . Using dq decoupling double-loop control , d -axis fixed Qref reactive power control , q -axis wind turbine output to strike at a wind speed maximum power tracking mechanism based on the maximum wind energy , after removing the mechanical losses ,use it as DFIG output active power reference value.

Δp_s , Δq_s was DFIG output instantaneous active and reactive power variation ; k_{g2}, k_{i2}, k_{g1}, k_{i1} were inside the controller, outer PI parameters.

When using test signal analysis the original circuit model DFIG , due to the full-controlled inverter power high-frequency electronic devices turned on and off the course , electrical damping can not converge .

This paper established a model of DFIG equivalent inverter controlled source simulation , integrated VSC AC side and DC side controlled voltage source controlled current source characteristics , will be simulated controlled sources DFIG rotor side and the network side using VSC,as in Figure 3 . High-frequency inverter through controlled source model without taking into account the full-controlled power electronic devices , so a test signal analysis electrical damping convergence, simulation time is much shorter.

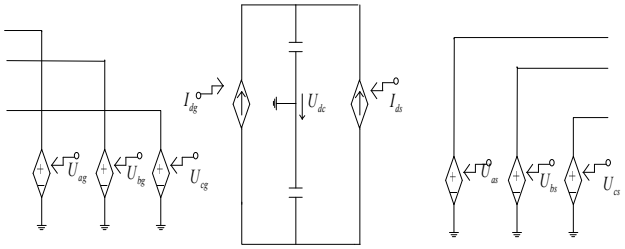

Fig.3 DFIG equivalent model of the controlled source converter

Verify the correctness of the equivalent model

Control input signal step change. After the wind turbine equivalent model is stable, the control input signal step change , the operation model shown in Figure 4 . When 10s the reactive power output of wind turbines from 0.04Mvar rises to 0.44Mvar. When 12s the wind turbine output active power increases from 0.66Mw to 0.96Mw.

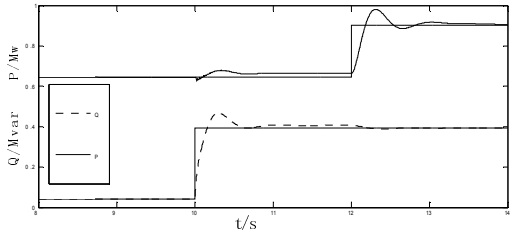

Fig.4 Command trace diagram of the control system in the equivalent controlled source model

As can be seen from Figure 4 , the input signal when changing settings , the equivalent model of the control system can quickly and accurately track settings. When the wind turbine output reactive setpoint changes , changes in reactive power output , active output basically unchanged ; when active setpoint changes , active output changes , reactive output basically unchanged. Active and reactive power output of the wind turbine can achieve decoupling control .

Test signal method analysis system SSCI characteristics

For the oscillation frequency λ of the system components , the electromagnetic torque increment can be expressed as:

$$\Delta\dot{T}_e = K_e(\lambda)\Delta\dot{\delta} + D_e(\lambda)\Delta\dot{\omega} \quad (1)$$

so:

$$\Delta\dot{T}_e / \Delta\dot{\omega} = D_e(\lambda) - jK_e(\lambda) / \lambda \quad (2)$$

$$D_e(\lambda) = \mathrm{Re}(\Delta\dot{T}_e / \Delta\dot{\omega}) \quad (3)$$

Steps to using the electrical test signal damping method is as following:

(1) in operating conditions , when the system enters the steady state , applying a small sinusoidal excitation generator rotor torque $\Delta T_m = \sum_a T_a \cos(a\omega_0 t + \Phi_a)$ bunch of sub-synchronous frequency $f = af_0$.

(2) When the system is re-entering the steady state , intercept the generator electromagnetic torque T_e and the generator speed ω on a common cycle .

(3) The amount of the two spectral decomposition to obtain the corresponding $\Delta\dot{T}_e$ and $\Delta\dot{\omega}$ of different frequency.

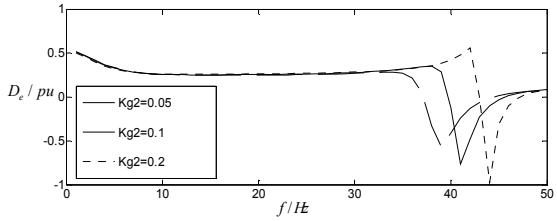
According to formula (3) can be calculated electrical damping torque coefficient.

Analysis SSCI Characteristics. The current study generally considered SSCI mainly affected by the rotor -side converter PI parameters and the degree of series compensation [8] . Therefore, the following article will be studied electrical damping computing systems , analyze the impact of these parameters on the SSCI . When the induction generator parameters set in Table 1 , the rotor -side converter in accordance with the PI parameters unchanged , according to the value shown in Table 2, the set wind speed is 10m / s.

Tab.2 The PI parameters of the rotor side converter

parameters	value
k_{g1}	0.01
k_{i1}	0.1
k_{g2}	0.1
k_{i2}	1.0

Set up the series was 20% , calculated on the electrical damping system . When setting the inner rotor -side converter proportional gain k_{g2} of 0.05, 0.1 and 0.2, respectively, in Figure 5 shows electrical damping coefficient curve with different inner loop gains.



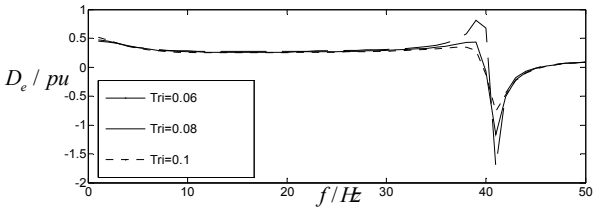


Fig.5 The electrical damping coefficient curve with different inner loop gains

Fig.6The electrical damping coefficient curve with different inner loop integration time constant

When electrical damping is negative, if the system damping of mechanical and electrical damping is negative , it may occur SSCI. As can be seen from Figure 5 , with the inner rotor side converter kg2 proportional gain is increased, the electrical frequency of the lowest point of the damper increases , the system gradually increases the frequency of the SSCI , electrical and negative damping system , the SSCI gradually increases. When setting the inner rotor -side converter integral time constant T ri = kg2 / ki2 were 0.06 and 0.08 and 0.1, respectively, The electrical damping coefficient curve with different inner loop integration time constant is shown in Figure 6 .

Conclusions

Based on PSCAD / EMTDC simulation platform for the establishment of a DFIG equivalent source inverter controlled grid model **,**then verify the correctness of the equivalent model , and pointed out higher simulation efficiency advantages of equivalent model. Analysis the impact of series compensation and rotor -side converter PI parameters characteristic of the SSCI based on test signal method and time-domain simulation method. The results show that increasing the degree of series compensation , inner gain constant increases and inner integral time decreases will help increase SSCI, outer ring of PI parameters has little effect on the SSCI .

Estimation of A State Vector of An Inertial Unit

Zhang huiping[1] , Pei Peng[1], Roger Ceschi[2] ,Olivier Rabreau[2]

[1] Beijing institute of Petrochemical Technology Beijing 102617

[2] Graduate School of Engineering France

Keywords: Inertial unit; kalman filter; matlab

Abstract. An inertial unit includes many parameters, such as: position, speed, acceleration and so on. Now estimate the acceleration and angular velocity may seem simple, because an accelerometer can provide a measure of acceleration and a gyroscope can provide a measure of angular velocity. Nevertheless, we will see below that this apparent ease of hiding the very real difficulties.The aim of this paper is not to recreate an complex inertial unit, but try to estimate the inclination angle and the angular velocity of an object by using some math filters, This problem we will not only tap away the complexity of the implementation of an inertial, but more importantly to use a math filter to make the prediction information and data fusion multi -sensors.

Introduction

Now more and more people become disabled because of ill, accident and something else. And a part of them may cover in rehabilitation center, but most part of them may stay in the wheelchair to live their left life, the wheelchair has become a most important tool in their life. They should control the wheelchair very well. But how does the doctor or the invalid them want to know they have already control the wheelchair very well.[1]

Our project is to build a system which will install in the wheelchair to access the people who drive the wheelchair.

The structure diagram of the project

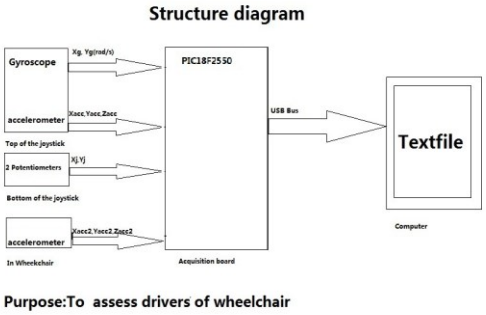

Fig. 1

We will use two kinds of sensors in this project:

Accelerometer:

• Detecting the proper acceleration of a movable. It brings us back accelerometer values of acceleration noise.

Gyroscope:

• Detecting the angular velocity of a movable. It returns values with gyroscope angular velocities noisy and biased.

Problems must be solved before the modeling

The difficulty of the problem is that the gyroscope has a bias that changes over time! And we do not know the shape of the drift.[2] But the bias of the gyroscope change very slowly, So, we can think that it does not move! And Before beginning a modeling system, we will make some assumptions about the mobile sensors.[3]

• First, we consider that the mobile does not undergo any acceleration
• Next, we consider the noise of the sensors as Gaussian
• It is considered that we should review the accelerometer values directly acceleration in meters per second
• It is considered that the gyroscope values we refer directly to angular velocities in radians per second
• Finally, we consider using the gyroscope in rehabilitation center (which is not too complicated to implement in practice).

Kalman Filter[4]

The Kalman filter model assumes the true state at time k is evolved from the state at (k − 1) according to

$$X_k = A_k \bullet X_{k-1} + B_k \bullet U_k + W_k$$

Where

- A_k is the state transition model which is applied to the previous state X_{k-1};
- B_k is the control-input model which is applied to the control vector U_k, And in our project, we don't use control system , So B_k is zero in our project;
- W_k is the process noise which is assumed to be drawn from a zero mean multivariate normal distribution with covariance Q_k.

$$W_k - N(0, Q_k)$$

At time k an observation (or measurement) Zk of the true state Xk is made according to

$$Z_k = H_k \bullet X_k + V_k$$

Where

- H_k is the observation model which maps the true state space into the observed space
- V_k is the observation noise which is assumed to be zero mean Gaussian white noise with covariance R_k.

$$V_k \sim N(0, R_k)$$

Note: The initial state, and the noise vectors at each step {x0, w1, ..., wk, v1 ... vk} are all assumed to be mutually independent.

A. Modeling of the object

To apply a Kalman filter, we must create the model of the project based on the parameters to be measured by the sensors.[5][6] Measuring the angular velocity of the inertial unit by the gyroscope (u) is obtained by adding the noise of the gyroscope (b_1) and the bias of the gyroscope (b) to the true value of the angular velocity of the inertial unit (a_1).

The measurement of the angle of inclination of the inertial unit by the accelerometer (a_M) is obtained by adding the noise of the accelerometer (b_2) to the true value of the angle of inclination of the inertial unit (a_2)

We deduce the following equations:

$u = a_1 + b + b_1$

$a_M = a_2 + b_2$

We can write these equations in matrix form Y = HX + B is called the measurement equation

- Y is called the measurement vector
- X is the state vector
- B, the noise vector
- H, the observation matrix

$$[a_M] = [0 \quad 1 \quad 0] \bullet \begin{bmatrix} a_1 \\ a_2 \\ b \end{bmatrix} + [b_2]$$

- we do not model the evolution of the angular velocity of the mobile. We will therefore also be considered to be fixed: $a_{1(k+1)} = a_{1(k)}$
- Finally, one can express the inclination of the movable as a function of the angular velocity at the preceding instant:

$a_{2(k+1)} = a_{2(k)} - a_{1(k)} \bullet \mathrm{T}_s$.

(Note: T_s is the sample period of the system).

Again, we can rewrite these equations in matrix form $X_{(k+1)} = A_{(k)} \bullet X_{(k)}$ called the equation of state

- $X_{(k+1)}$ is the new state vector
- $X_{(k)}$ is the former state vector
- $A_{(k)}$ Ak is the transition matrix

$$\begin{bmatrix} a_{1(k+1)} \\ a_{2(k+1)} \\ b \end{bmatrix} = \begin{bmatrix} 1 & -T_s & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \bullet \begin{bmatrix} a_{1(k)} \\ a_{2(k)} \\ b \end{bmatrix}$$

To use the Kalman filter, we are missing two matrices appearing in the calculation: the covariance matrix of measurement noise and the covariance matrix of control noise.

Since we have two sensors with Gaussian noise, the covariance matrix of measurement noise is a matrix with one dimensional, the square of the standard type of sensor noise. (Indeed, the noises of the sensors are considered to be Gaussian and uncorrelated with each other)

$R = (\sigma_1^{\,2})$

- σ_1 is the noise standard deviation of the accelerometer

Finally, the covariance matrix of the control noise is the system modeling errors. It is through this matrix that the errors in modeling (here, it was estimated that the bias and angular velocity were

constant when in reality it is false) will be "erased". This matrix is a diagonal matrix of dimension three (it was a state vector of size 3). The terms on the diagonal correspond to the square of the standard deviations of the maximum error that we allow for each of the parameters to be estimated. This matrix is to be determined empirically based on the problem.

Please understand that if we set the error terms too small compared to reality, then the Kalman filter will not happen to rectify the errors of the model and make biased estimates. By constant, if the error terms are too large compared to reality, then the model will not be biased, but the estimates produced are of poor quality (the error covariance will be important)

The difficulty of the Kalman filter is to properly estimate the covariance matrix of control noise in order to have an estimate as accurately as possible without having bias.

$$Q = \begin{bmatrix} \varepsilon_{a_1} & 0 & 0 \\ 0 & \varepsilon_{a_2} & 0 \\ 0 & 0 & \varepsilon_b \end{bmatrix}$$

- ε_{a_1} is the variance of the maximum allowable error on the modeling of the angular velocity (equation of state)
- ε_{a_2} is the variance of the maximum allowable error on the modeling of the slope (equation of state). In our example, this value should be forced to 0. Indeed, the model for the slope was completely determined by the previous inclination and angular velocity before. There is no mistake.
- ε_b is the variance of the maximum allowable error on the modeling of the gyro bias (equation of state)[7,8]

B. Application of the Kalman filter

- **Predict**

Predicted state estimate	$\tilde{X}_{(k\|k-1)} = A \bullet \tilde{X}_{(k-1\|k-1)}$
Predicted estimate covariance	$P_{(k\|k-1)} = A \bullet P_{(k-1\|k-1)} \bullet A^T + Q_k$

- **Update**

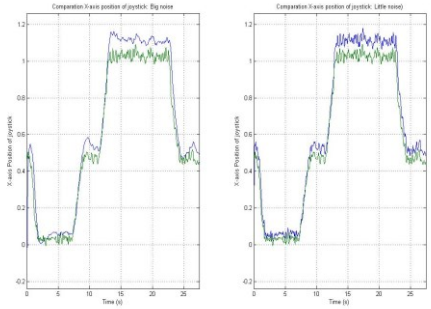
Innovation or measurement residual	$\tilde{y}_k = z_k - H_k \tilde{X}_{k\|k-1}$
Innovation (or residual) covariance	$S_k = H_k P_{k\|k-1} H_k^T + R_k$
Optimal Kalman gain	$K_k = P_{k\|k-1} = P_{k\|k-1} H_k^T S_k^{-1}$
Updated (*a posteriori*) state estimate	$\tilde{X}_{k\|k} = \tilde{X}_{k\|k-1} + K_k \tilde{y}_k$
Updated (*a posteriori*) estimate covariance	$P_{k\|k} = (I - K_k H_k) P_{k\|k-1}$

Note: $X_{(k|k)}$ as the estimate of the new state vector and $P_{(k|k)}$ as the new covariance matrix of the estimated state. This matrix will tell you about the accuracy of the estimate of each parameter.

Simulation with MatLab

After making the model, we only need choose the suitable process-based error and suitable measurement error.

Here is the result of simulation of this example in Matlab.



Conclusions

Kalman filter is suitable for our system the reason is that our system is a linear system. When kalman filter was used, creating a model of this system was very easy and it can minimize the variance of the estimation. And when the kalman filter was used in our system The matrix of the noise was the only thing we need get, it's an very easy task. So kalman filter is suitable for our system.

Abstract. Packet loss during network transmission through internet has negative influence on vehicle remote steering operation. Model of the remote steering system was built to analyze the steering quality. On basis of former study, a kind of packet loss compensator was designed from the aspect of predictive compensate control using hybrid pi-sigmoid fuzzy neural network. Simulation results showed that the compensator worked effectively. It was able to reduce the bad influence of packet loss during remote vehicle steering procedure.

Introduction

Statistics about the traffic accidents from year 2007 to 2009 [1,2,3] show that risky-driving-related traffic accidents account for from 54% to 90% of the total, such as fatigue driving, driving after drink, and so on. If the driver is in risky state, there will be a significant decline of capacity in vehicle steering control, decision making and implementation, which is one of the key reasons to raise both injury rates and death rates. From this point of view, remote vehicle steering shows its great practical significance.

Development and prevalence of internet has made it feasible and convenient for remote vehicle steering. There will be the phenomenon of time delay and packet loss when packets are transferred. Researches on reducing the affect of packet loss can be classified into two major areas so far. One focuses on developing and improving the User Datagram Protocol, such as TCP OVER UDP and UDT [4]. However, these methods are not applicable for public internet. The other one aims at a set of control theories and strategies. SOGLO has invented a compensate estimator to deal with delay and packet loss problem so as to improve control performance [5]. LONG has designed open-loop estimator and closed-loop estimator separately according the whether packet loss phenomenon occurred or not [6]. However, both of the theories make assumptions and requirements on delay and packet loss rate, which are impossible for real internet transfer.

This work is going to present a packet loss compensator constructed by the hybrid pi-sigmoid fuzzy neural network theory without any prerequisites for internet parameters.

Influence of Packet Loss on Internet Based Remote Vehicle Steering

Fig.1 shows a simplified schematic for internet-based remote vehicle steering control. Symbol r stands for the reference input steering angle. Go(z) is a simplified static discrete model of a certain vehicle steering system with a sampling period Ts as 10 milliseconds.

$$G_o(z)=\frac{A(z^{-1})}{1-B(z^{-1})}=\frac{a_1z^{-1}+a_2z^{-2}+\cdots+a_mz^{-m}}{1-b_1z^{-1}-b_2z^{-2}-\cdots-b_nz^{-n}}=\frac{0.025z^{-1}+0.178z^{-2}}{1-0.56z^{-1}-0.32z^{-2}-0.61z^{-3}} \quad (1)$$

As we can see, the controller and the object controlled are separated by internet. Internet is the communication channel for them. v(k) stands for control values from the remote controller. y(k) means steering angle of the front wheels.

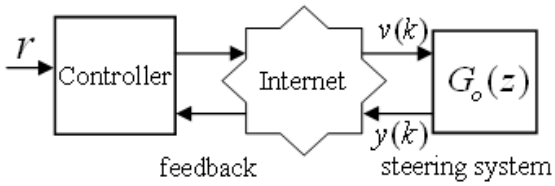

Fig.1 Schematic of the internet based remote vehicle steering

Suppose that l consistent packets are lost from the k0th sampling, then the input control values of the steering system will change to v(k0+i) = v(k0+i-1) = ⋯ = v(k0) where i=1,2,…,l. Considering of Eq.1, when $i \geq m$, we come to a result as

$$y(k_0+i) = v(k_0)\sum_{j=1}^{m} a_j + \sum_{h=1}^{n} b_h y(k_0+i-h) \quad . \tag{2}$$

Eq.5 tells us that when the number of the consistent lost packets is bigger than that of the model's zeros, pattern of the remote steering control process will turn from close-loop to open-loop. This probably results in the risk to traffic accidents.

Structure of The Hybrid Pi-sigmoid Fuzzy Neural Network

In previous study [8], we successfully developed a robust controller to kick off the effects of transfer delay. Here we will focus on the matter of packet loss, trying to work out a predictive compensate control strategy. Histories of the input control information will be used to predict the current lost one. Since packet loss phenomenon happens at random and is time-varying, the predict arithmetic must have both latest short-term control law parameters identification function and fast dynamic self-learning ability. Thus, we prefer to use both the fuzzy logic and neural network modeling, which are the basis of hybrid pi-sigmoid fuzzy neural network theory.

Tagaki-Sugeno fuzzy logic can be described as $R^i : if\ x_1\ is\ A_1^i\ ,\ x_2\ is\ A_2^i\ ,\cdots, x_m\ is\ A_m^i$, $then\ y^i = f^i(x_1, x_2, \cdots, x_m)$. R^i (i=1,2,…,n) means the ith rule. Parameter n means total number of the rules. yi means the conclusion of the ith rule. xj (j=1,2,…,m) are the premise input variables. m is the count of the input variables. A_j^i stand for the fuzzy sets. n_i means number of the domains xj.

Fig.2 shows the Tagaki-Sugeno fuzzy logic implemented by a pi-sigmoid neural network.

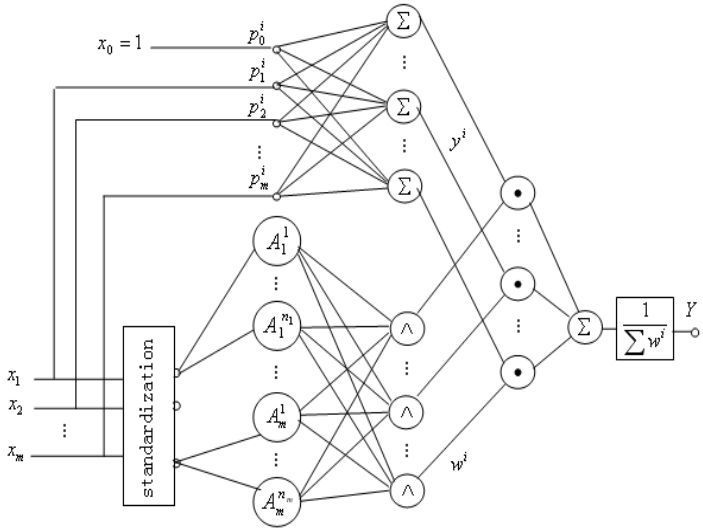

Fig.2 Structure chart of hybrid pi-sigmoid fuzzy neural network

In Fig.2, symbol Σ means addition operation. Symbol $\bullet$ means multiplication. Symbol $\wedge$ means taking the minimum. x0 takes value as 1 all the time. Thus, we get the output of the network as

$$Y = \sum_{i=1}^{n} w^i y^i \Big/ \sum_{i=1}^{n} w^i \quad , \tag{3}$$

where $y^i = \sum_{j=0}^{m} p_j^i x_j$, $\mu_{A_j^i} = \exp[-(x_j - a_j^i)^2 / b_j^i]$, and $w^i = \mu_{A_1^i}(x_1) \wedge \mu_{A_2^i}(x_2) \wedge \cdots \wedge \mu_{A_m^i}(x_m)$.

Training Algorithm of The Neural Network

Training of the hybrid pi-sigmoid fuzzy neural network aims at adjusting the consequent parameters p_j^i as well as the premise parameters a_j^i and b_j^i. If we mark the output of the network as Y^d and define the target deviation function as

$$E = \frac{1}{2}(Y^d - Y)^2, \tag{4}$$

then according to the gradient method, there will be

$$\frac{\partial E}{\partial p_j^i} = \frac{\partial E}{\partial Y} \cdot \frac{\partial Y}{\partial p_j^i} = -(Y^d - Y) \cdot \left[\frac{\sum_{i=1}^{n} w^i y^i}{\sum_{i=1}^{n} w^i} \right] \Big/ \partial p_j^i = -(Y^d - Y) \cdot \frac{w^i}{\sum_{i=1}^{n} w^i} \cdot \frac{\partial y^i}{\partial p_j^i}. \tag{5}$$

Then, we get

$$\Delta p_j^i = -\alpha (Y^d - Y) \cdot w^i \Big/ (\sum_{i=1}^{n} w^i) \cdot x_j, \tag{6}$$

, where α stands for the learning speed of the consequent parameters.

We must notice that gradient method is no longer applicable when we try to calculate the increments of a_j^i and b_j^i, since there exists such nonlinear operation as taking the minimum. We could not make certain about which component parameter has raised the deviation. In this case, we adopted a one-step-search method. Firstly, we assumed that it was the corresponding component parameter that had raised the deviation. Secondly, we calculated the deviation of the network's output, which was then used to update the network's nodes. Thirdly, we recalculated the output deviation of the updated network. Finally, we made a compare about the deviations to check out which update resulted in the best results. We recognized the best one to update its corresponding nodes and restored the other nodes. Following these rules, we have reached

$$\frac{\partial E}{\partial a_j^i} = \frac{\partial E}{\partial Y} \cdot \frac{\partial Y}{\partial a_j^i} = \frac{\partial E}{\partial Y} \cdot \frac{\partial Y}{\partial w^i} \cdot \frac{\partial w^i}{\partial a_j^i} = -2(Y^d - Y) \cdot \frac{y^i \sum_{i=1}^{n} w^i - \sum_{i=1}^{n} w^i y^i}{(\sum_{i=1}^{n} w^i)^2} \cdot (x_j - a_j^i) \cdot w^i / b_j^i \tag{7}$$

as well as

$$\Delta a_j^i = -2\beta (Y^d - Y) \cdot \left[y^i \sum_{i=1}^{n} w^i - \sum_{i=1}^{n} w^i y^i \right] \cdot (x_j - a_j^i) \cdot w^i \Big/ \left[b_j^i (\sum_{i=1}^{n} w^i)^2 \right], \tag{8}$$

where β stands for the learning speed of the premise parameters. Similarly, we obtained

$$\Delta b_j^i = -\beta (Y^d - Y) \cdot \left[y^i \sum_{i=1}^{n} w^i - \sum_{i=1}^{n} w^i y^i \right] \cdot (x_j - a_j^i)^2 \cdot w^i \Big/ (b_j^i \sum_{i=1}^{n} w^i)^2. \tag{9}$$

Principle of The Packet Loss Compensator

A novel packet loss compensator was designed as shown in Fig.3 with the help of hybrid pi-sigmoid fuzzy neural network theory showed above.

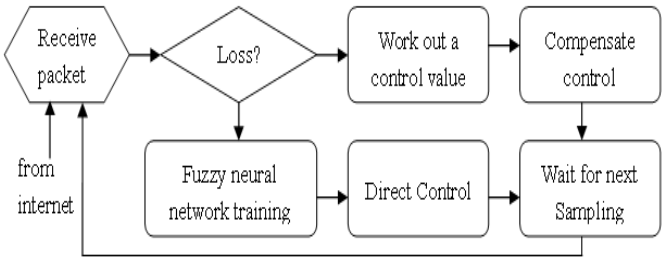

Fig.3 Procedure chart of packet loss compensator in remote vehicle steering system

There are two auto-switch procedure modes for the compensator. One is called as learning mode. This mode works when data packets that carry the control information are transferred successfully. Control information received are not only used to drive the vehicle steering system but also used to train the neural network and adjust p_j^i, a_j^i and b_j^i. As a result, transfer function of the neural network is consistent with the latest short-term control law of v(k).

The other mode is called predictive compensate control mode. This mode works when the packets are lost. In that case, the auto-trained neural network will work out a predicted control value to help drive the steering system so as to guarantee a complete steering process.

Simulation and Results

There were some specifications for the simulation.

1) We took control value v(k) and its first-order difference $\Delta v(k) = v(k) - v(k-1)$ as input training samples of the hybrid pi-sigmoid fuzzy neural network, and then made v(k+1) as its ideal output. Thus, m got the value as 2.

2) Fuzzy sets were divided as {NL, NM, NS, ZE, PS, PM, PL}, which correspondingly meant negative-large, negative-middle, negative-small, zero, positive-small, positive-middle and positive-large. As we could see, there were 49 rules, thus to say n equaled 49.

3) The consequent parameters were initialized as $p_j^i = 4$. Its learning speed α was defined as 0.01. While the premise parameters were initialized as $a_j^i = 0.95$ and $b_j^i = 0.8$, and its learning speed β was defined as 0.005.

4) Network transfer delays were set as a const value of 250 milliseconds. Besides, packet loss sampling intervals were defined as k∈ {15,25} ∪ {55,70} ∪ {125,135} ∪ {165,180} ∪ {220,235} ∪ {300,315} ∪ {400,425} ∪ {455,460} ∪ {480,490}.

5) Control arithmetic followed a delay-dependent robust control theory that we had already provided in [9].

Following the specifications, we sent a command for Go(z) to steer 45 degrees from the remote control terminal through the constructed internet environment. When regardless of the case of ground resistance, the steering angles of the front wheels measured were shown in Fig.4.

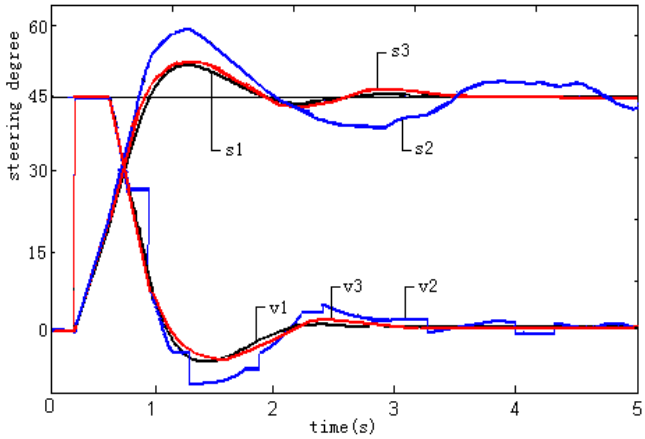

Fig.4 Steering angles measured when perform a 45 degree remote steering

In Fig.4, curve v1 and s1 stand for the input control value and steering angle respectively when there is no packet loss. v2 and s2 stand for the ones when there is packet loss but without help from the compensator provided above. v3 and s3 stand for the ones with the help of the compensator.

It is clear that packet loss will make remote steering lack of valid control input, which results in a heavy over-steering, steering fluctuations and instability. However, with the help of the compensator constructed by the hybrid pi-sigmoid fuzzy neural network, remote steering process is almost same as the one when no data packets are lost. It helps to decrease the over-steering angle and make the steering both fast and stable, and what's more, without a static deviation.

Conclusions

The compensator constructed by the hybrid pi-sigmoid fuzzy neural network is able to train automatically and dynamic adjust its parameter on line fast and effectively. It is capable of digging out the latest short-term control law from the control values received and providing an alternative compensate control value when data packet loss happens. Results of the simulation prove the effectiveness of the theory we have provided in this paper. It may be a solution to kinds of remote control and operation based on internet. We will put a further study on it.

Abstract. Telescope laser pointer is generally used firearms and other light weapons systems, to ensure accurate light weapons capable of targeting, this paper presents a telescope system automatically detects a laser pointer, laser pointer can be the role of the distance, the laser divergence angle of the laser spot size of the laser optical axis adjustment range and the laser optical axis deviation and other parameters were measured. In this paper, the detection system structure, optical structure was designed; proposed laser pointer detection principle of the parameters; and software design. At last, to meet the requirements of this system has been experimentally derived by experimental verification, measurement accuracy.

Introduction

Telescope laser pointer is generally used firearms and other light weapons systems; light weapons can ensure accurate targeting and thus damage the target at the expected location. With small arms vigorously development, the telescope laser pointer parameter testing higher and higher demands are proposed. However, the majority of domestic research department no new weapons testing and calibration equipment laser pointer, not objective advantage product technical condition, difficult to ensure the quality of production. For these reasons, the laser pointer to the gun telescopic system design a multi-parameter testing system, the measurement system of the telescopic system in laser designator, laser divergence Angle, the role of distance laser spot size, laser optical axis adjustment range and measure the parameters of the laser optical axis deviation vector.

System Architecture Design

The measuring instrument is composed of parallel light tubes, CCD camera, partition plates and measuring system consists of a laser light source, by the computer and analysis software computing systems, and fastening systems as well as the composition of the sample holder which supports the protective effect of the mechanical system composed by a shield composed.

The detector works as follows: Parallel light pipe and coaxial telescopic system, the telescopic system provides limited far or infinity target, when a laser designator light coaxial with telescopic system, the laser beam and optical axis coincidence of parallel light pipe, put CCD camera, the focal plane of the objective by recording the movement of the spot on the CCD camera, calculate the corresponding parameters using the computer program.

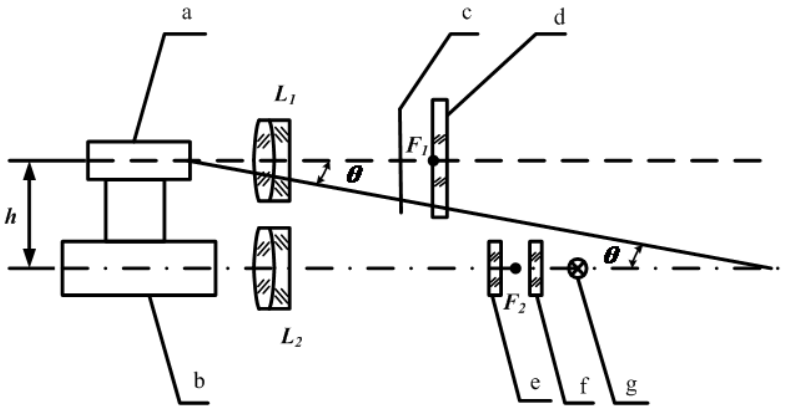

Fig. 1 Schematic diagram of the optical test system

(a) the measured laser pointer (b) telescope system (c) attenuator

(d) CCD Camera (e) reticle (f) Feather Glass (g) laser light source

As shown in Figure 1, will have instruction function of telescopic system frame fixed on the sample, the telescope system(b） with a laser pointer(a） and the distance parallel to the axis of the theoretical *h*, so that the collimator (b) coaxial with the telescope system, by laser light source (g), the reticle (e), MAO glass (f), object collimator lens L_2 telescope system to provide limited or unlimited far away targets. When the laser light source and telescopic system coaxial, the laser beam with parallel light pipe (a) optical axis coincidence, Placed at the focal plane of the objective CCD camera (d), by recording the CCD camera (d) on the spot of mobile.

Indicator parameter detection principle

Indicator measuring principle of the parameters as follows:

1) Laser divergence angle measurement: the laser beam through the collimator lens L_1, attenuators (c) image on the CCD, collimator focal length by $f^{'}$, Measured on the spot by CCD image height y ', by type (a) calculating the laser divergence Angle.

$$\theta = \arctan\frac{y'}{f'} \tag{1}$$

2) range measurements: measured distance l and calibration distance measured $l^{'}$ place, the intensity of illumination in the CCD for E and E', Spot diameter respectively $D = D_0 + 2l\tan\theta$ and $D' = D_0 + 2l'\tan\theta$, θ as the divergence Angle, D_0 as the starting point in a laser designator (a) the diameter of the output beam, flare area represented by A and A' respectively, by the formula (2) below.

$$\begin{cases} A = \pi\left(\dfrac{D}{2}\right)^2 = \pi\left(\dfrac{D_0}{2} + l\tan\theta\right)^2 \\ \quad = \pi\left(\dfrac{D^2{}_0}{4} + D_0 l\tan\theta + l^2\tan^2\theta\right) \\ A' = \pi\left(\dfrac{D}{2}\right)^2 = \pi\left(\dfrac{D_0}{2} + l'\tan\theta\right)^2 \\ \quad = \pi\left(\dfrac{D^2{}_0}{4} + D_0 l'\tan\theta + l'^2\tan^2\theta\right) \end{cases} \tag{2}$$

By the light intensity and the spot size is inversely proportional to the formula (3)

$$\frac{E}{E'} = \frac{A'}{A} = \frac{\dfrac{D^2{}_0}{4} + D_0 l'\tan\theta + l'^2\tan^2\theta}{\dfrac{D^2{}_0}{4} + D_0 l\tan\theta + l^2\tan^2\theta} \tag{3}$$

By calculating the type, can solve the measured distance *l*.

3) laser optical axis deviation measurement: first of all, according to a predetermined working distance, the optical axis offset and the focal length of the parallel light pipe calculated under normal circumstances indicating light spot on the focal plane off center distance (CCD optical axis). Comparing the actual and the ideal offset of the offset difference between the optical axis of the laser to obtain the amount of deviation.

4) divergence angle of the laser beam, the laser spot size measurements: laser CCD optical axis parallel incident, according to the CCD lens focal length and light spot on the CCD pixel number, of using computing software can calculate the Angle of laser beam are scattered and spot size.

5) laser optical axis adjustment range of measurement: the laser pointer laser summicron-m is parallel to the CCD, when the laser pointer along a certain direction, according to the amount of light spot on the CCD jitter flare adjusting range can be calculated.

Software Interface Design

The software consists of image pre-processing, and file manipulation functions to measure three modules, the following will introduce based on interface design part of the three modules, interface is shown in Figure 2.

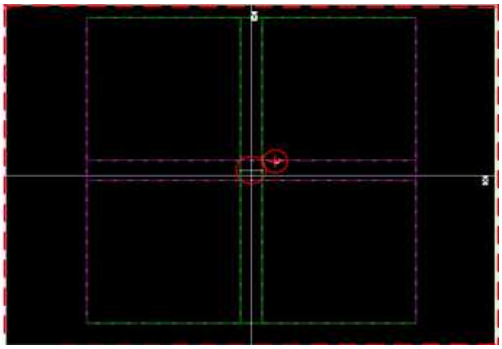

Fig. 2 Software interface Figure

Experiment

In order to test the effectiveness of the system, qualified for a certain type of telescope to detect laser pointer experiment. This laser pointer is known technical indicators are as follows:

(1) divergence angle of the laser beam:

$$\theta \le 1mrad$$

(2) the amount of spot move: 60 meters distance of laser speckle is 1.5 mrad;

(3) the laser optical axis adjustment range and deviation: along the horizontal (vertical) direction to adjust the optical axis, the adjustment range in the horizontal (vertical) direction within $\pm 15mil$ walk, move in the vertical deviation amount (horizontal) direction within $\pm 1mil$;

(4) the role of distance: emitted from the laser pointer in the 60 meters at a distance, can clearly see the laser spot, the background illumination $\le 50LX$ this system is used for detecting the experimental data shown in Table 1.

Table 1 Measured Data Sheet

	Spot radius (mm)	Beam angle (mrad)	The amount of walking (mrad)	The adjustment range (mil)	Deviation (mil)
the first group	0.034	0.242	0.172	(up and down) -12.712,10.828 (Left and right) -10.692,13.592	(Left and right) -0.235,0.369 (up and down) -0.398,0.632
the second group	0.030	0.218	0.559	(up and down) -12.365,14.852 (Left and right) -12.582,11.226	(Left and right) -0.352,0.563 (up and down) -0.523,0.365
the third group	0.038	0.276	0.395	(up and down) -13.635,10.358 (Left and right) -10.582,12.368	(Left and right) -0.254,0.357 (up and down) -0.329,0.368

Conclusions

Telescope system automatically detects the laser pointer realized the automatic acquisition and automatic processing of data, the role of the laser pointer can be the distance, the divergence angle of the laser, the laser spot size, and the adjustment range of the optical axis of the laser optical axis of the laser parameters such as the amount of deviation is measured. Through this system to a certain type of qualified laser pointer detection experiments shows that this system is effective for a laser pointer quantitative assessment of performance parameters.

The Development of Underground Personnel Data Terminal Based on RSSI Location

Hongyi Li, Chuanzhong Chen

Xinxiang Vocational and Technical College, Henan, Xinxiang, 453006

KeyWords: RSSI; CC2431; Underground; Location

Abstract: Based on the emerging ZigBee wireless RF communication technology, this paper presents the design of a miner information collection terminal. The entire system is designed around the CC2431 SoC hardware circuit, through ZigBee networking, to achieve the location of underground environment and miner vital signs data acquisition, so that it can provide effective help to quickly carry out rescue work.

Introduction

Currently, most major mine safety monitoring system applies the wired way for data transmission, once the mine disaster, equipment and cables tend to be compromised and cannot provide useful information for searching and rescue work after the mine disaster, due to ground monitoring persons cannot master the underground operations and the distribution of personnel, so the rescue of persons in distress, safety ambulance is inefficient, rescue result is poor. This paper designs a personal data mobile terminal equipment, worn on a miner's helmet, which can simultaneously capture miner's body temperature, heart rate and other vital signs and the surrounding environment's oxygen gas concentration. Through ZigBee network, parameters will be collected and terminal address information will be sent to the ground command center by wireless transmission. In the center of the monitor screen, the exact location of each miner can be seen, even mine resulting roadway collapsed, causing interruption of wireless communications, the distribution of the moment by the former mine personnel can also provide the basis for drilling. By drilling, the oxygen can be sent to miners for the rescue to gain time, and a new ZigBee gateway can be sent to the distress area by drilling. ZigBee network will automatically find and establish new contacts to terminal for the ground command center miners for more information.

1 The overall structure of the data terminal

The system structure block diagram is shown in Figure 1, here, ME2-O2 is an oxygen concentration sensor, for acquiring down-hole oxygen concentration data, and which outputs a current signal proportional to the concentration of oxygen, MH-440V/D is the methane concentration sensor for detecting underground gas concentrations, DS1631 is a digital temperature sensor for miner temperature acquisition, HK2000A pulse sensor is used to capture the heart of miners. CC2431 is a ZigBee wireless location chips, during 2.4G ISM band wireless achieving data transmission function, which integrates a 51-core chip microcontroller with a 14bit A /D. The framework structure of the data terminal, CC2431 as to the core components, is shown in Figure 1.

In Figure 1, oxygen concentration and gas concentration measurement devices, mainly detect for underground miners usually work environment the oxygen concentration and gas concentration. When the gas exceeds safe limits, sound and light alarm, when faced with mine disaster, real-time environmental parameters in which the trapped miners timely deliveries to the command center, easy to carry out rescue work.

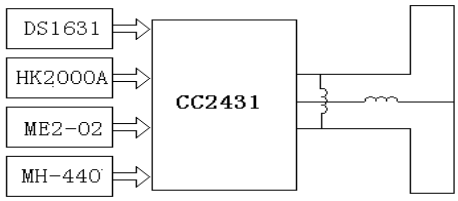

Figure 1 The system structure block diagram

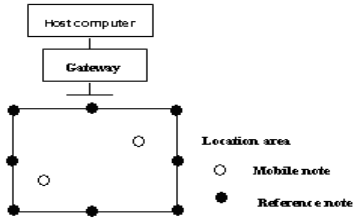

Figure2 Positioning system block diagram

2 Environmental information acquisition circuit

2.1 Oxygen concentration sensor

Employing electrochemical oxygen sensor ME2-O2, the working mechanism is electrochemical primary batteries: Cathodic oxygen reduction reaction occurs in the sensor, an oxidation reaction at the anode. Oxidation and reduction reactions to produce a current proportional to the oxygen concentration, follow Farada's law.

Its main technical parameters:

Range: 0～25%vol

Maximum measurement limit: 30%vol

Response time: （T90） ≤15S

Temperature range: －20℃～+50℃

2.2 Low- density gas sensor

Used to detect the ambient gas in the coal mine gas concentration, the main component of the gas is methane, gas concentration measurements uses the MH-440V/D infrared gas sensor. The sensors use non-dispersive infrared (NDIR) principle to detect CH4 present in the air, with good selectivity, without oxygen dependence, stable performance, long life, built-in temperature sensor for temperature compensation. Working voltage 3～5V, the measurement range 0～5%vol.

The output of oxygen concentration and gas concentration sensor is a voltage signal, through the filter circuit to filter out interference, evacuation 14bit A / D channel of CC2431 for analog / digital conversion.

2.3 Measurement of vital signs

The data terminal collection is miners' pulse and temperature data in distress, which are relatively easy to be acquired, in the case of cross-referenced to reflect the basic vital signs of the miners. Since the terminal is placed on the outside of the miners' helmets, body temperature and the pulse collection depend on the nearest principle. Temperature acquisition with a DS1631integrated temperature sensor, which connects CC2431 through the I2C bus and can directly output the measured temperature digital, without going through A / D conversion, the resolution can be adjusted. At 12-bit resolution, it may be up to 0.0625 ℃, after correction accuracy in near 37 ℃ measurement accuracy up to ± 0.1 ℃. Pulse acquisition using HK-2000A integrated pulse sensor , PVDF piezoelectric film, temperature compensation, signal conditioning circuitry are integrated within the HK-2000A integrated pulse sensor, the output pulse is in synchronization of pulse signal fluctuations . The PVDF is placed inside the helmet, close to the temple, used to feel the vibration of the temporal artery, the output pulse signal to the CC2431 counting unit measuring the vibration frequency of temporal artery, converted into pulse data.

Since temperature and output pulse signal are all digital, it no longer requires signal conditioning and analog / digital conversion, simplifying the circuit design.

3 ZigBee-wireless location network based CC2431

3.1 Construction of wireless location network

TI produces location engine CC2431 with hardware, based on RSSI (Received Signal Strength Indicator) technology, the location of the own node can be accurately calculated based on the received signal strength and the known reference point, and its location information is transmitted to the receiving end, achieving 3 ~ 5m positioning accuracy and resolution of 0.25m . It operates in the 2.4GHz ISM band, on-chip integration of ZigBee frequency (RF) front-end , memory, and 8051 controllers. Wireless Location System is composed of two kinds of nodes: a plurality of reference nodes and mobile nodes. The reference node is a fixed node, its position is known. This node can send data packets to each other information on each location through the Internet. The mobile node receives the data from the respective reference nodes, by measuring the received signal strength and the position information obtained from the reference node to calculate the own position by location engine. Figure 2 is a block diagram of the RSSI positioning system.

The role of each part is as follows:

(1) Host computer: a host connects to the reference node through a gateway, to manage the reference node such as setting coordinates of the reference node, and receives the data from the reference node via a gateway, on the screen can observe the location of each mobile node and various information collected by the mobile node.

(2) Gateway: the gateway is placed in the roadway, whose core is a CC2340, acting as a bridge between the reference node and the host, through fiber optic and CC2340 long-distance communications, ZigBee network is composed of CC2340 and reference node, the mobile node collected to transmit to the host.

(3) The reference node: fixed coordinate specified by the user, and supplies the coordinates and the average RSSI value for the mobile node.

(4) The mobile node: having internal positioning engine, the coordinates of its own can be calculated based on a fixed coordinates value of the reference RSSI node, and sends the coordinates , ID number to the gateway .

To ensure accuracy, multiple reference nodes are arranged on both sides of the roadway, forming a wireless network. Miners nodes computes their position in the located network, and their position, ID, environmental information and miners vital signs and other information, real-time wireless upload to the host computer. On a large screen in the center of the ground control room, computer images clearly indicate precise location of each miner, accuracy 2.5m^2.

3.2 Location algorithm based on RSSI

CC2431 positioning algorithm is based on the received RSSI (received signal strength indication) value. RSSI value will decrease with increasing distance:

$$RSSI = -(10n\log_{10}d + A) \tag{1}$$

Where, n is signal propagation constant, d is the distance between the sender, A is signal strength a meter far from the sender.

For mobile node M (x, y), the distance equation between two points in the plane, the equation can be obtained:

$$\begin{pmatrix} (X_1 - x)^2 + (Y_1 - y)^2 \\ M \\ (X_n - x)^2 + (Y_n - y)^2 \end{pmatrix} = \begin{pmatrix} d_1^2 \\ M \\ d_n^2 \end{pmatrix} \tag{2}$$

A linear transformation represented by the formula (2):

$$2A\begin{pmatrix} x \\ y \end{pmatrix} = B \tag{3}$$

$$A = \begin{pmatrix} X_1 - X_n & Y_1 - Y_n \\ M & M \\ X_{n-1} - Xn & Y_{n-1} - Y_n \end{pmatrix}$$

$$B = \begin{pmatrix} d_n^2 - d_1^2 - X_n^2 + X_1^2 - Y_n^2 + Y_1^2 \\ d_n^2 - d_{n-1}^2 - X_n^2 + X_{n-1}^2 - Y_n^2 + Y_{n-1}^2 \end{pmatrix}$$

Using the least squares method to get the coordinates of the mobile node:

$$\begin{pmatrix} x \\ y \end{pmatrix} = \frac{1}{2}(A^T A)^{-1} A^T B \tag{4}$$

3.3 The experimental results

In order to verify the effect of the positioning of the system, we do field tests in an office building's underground car park, having been completed but not put into use. Selecting length of 100 meters and wide of 6 meters as experimental zone, place 10 reference nodes evenly every25 meters around the spaced, the computer is placed in approximately 60 meters of 20 floors. Communications between gateway and computer test area using the RS485 level way, the dialogue between the two communicate using walkie-talkies, and upload data update once per second. Testing personnel wear data terminal during the test zone to run fast moving , uploading data to located information significantly lag; when less than 5Km / h speed mobile, data upload timely, no lag, positioning error <10m; when stationary, positioning error <5m, In the three cases, environmental parameters and vital signs are stable and reliable. After testing, the design meets the requirements in the whole.

4 Conclusion

RSSI-based location data terminal Underground staff is successfully developed, resolving the miners accurate positioning issues in time when the mine disaster. More importantly, real-time vital signs every miner and its surrounding environment information can be able to be got for rescue work smoothly to provide effective help. With this system, the ground control personnel can grasp the operation and distribution of underground personnel to improve safety ambulance efficiency with some promotional value.

The design of embedded video monitoring system based on DSP processor

Wenbin Hu

Engeneering department ,Xijing University,xi'an,china

Keyword: Video monitoring, Linux operating system, Video losing

Abstract: This paper designs a embedded video monitoring system based on ARM processor Ep9315 and TMS320DM642, and using embedded Linux operating system. In the system, video capturing module uses the video decoder TW2814. In order to capture better data, the control of TW2814 is needed. Through the imitation of I2C bus, the driver provide the application with the function of the setting of capturing parameters such as hue, color saturation, contrast and brightness, and the check of video losing.

Introduction

With the development of technology and the advancement of people's living standard, video monitoring system is widely used in the industry, security field and daily life. Video monitoring technology, combining the technology of computer, multimedia, telecommunication and network, is one of the focuses that are being researched and it has extensive future and practical value. With development of the embedded system and the degree of the integration of the chips, embedded video monitoring technology is getting more and more attention and being applied in many occasions[1]. Monitoring system can be used to campus safety monitoring, test monitoring, urban traffic monitoring, etc, and bring people good living environment.

1 Embedded video monitoring system overview

Embedded video monitoring system is composed of the collection part, coding part, transmission part, the controlling and display section. In the acquisition part, it needs to provide a full range of video monitor for completing analog video capture, while video loss detection function needs to be provided. When encoding, the image information acquisition should be encoded. In the transfer section, the image needs to be transmitted in real time after encoding, achieving the transmission in a variety of ways to meet the needs of different users, and is transmitted with low loss and requires a reliable transmission quality. In the display portion, the system needs to achieve real-time decompression of the video data playback, the video data stored in the video, the playback of history video recording, setting the alarm of video-interest part, the alarm time analysis and management. In the control section, you need to control the focal length of the camera aperture, image brightness, contrast, hue, saturation adjustment, image compression quality, frame rate control, PTZ control and external device control.

Because of the continuous powerful function, the application of embedded video monitoring system is also more extensive. Now, it can be used in security, access to information and command scheduling, providing a variety of services for production process control, security in large public facilities, medical care, distance education[2].

2 Hardware structure of embedded video monitoring system

The embedded system based on ARM processor, with its own rich resources, low power, low cost, is supported by many vendors, more and more applications in a variety of embedded systems requiring complex control and communication functions. As a dedicated digital processing circuit, DSP digital signal processing capability is very powerful, but more difficult to achieve task management, communications, human-computer interaction and other functions. If combining these two processors together, that is, the DSP combines the acquisition circuit sampling and processing signals, the ARM processor, as a platform, sends the results after DSP to the user for further

processing, and provides a graphical friendly interactive environment, completion of data analysis and network transmission and other functions, which will maximize the function of both directors[3].

The embedded video monitoring system is composed of the ARM and DSP dual-processor, ARM processor uses a Cirrus Logic's EP9315, DSP is TI's TM320DM642. In this way, we can take full advantage of the powerful DSP data processing capability, and the advantages of ARM processors in control. EP9315 processor is a highly integrated system on chip processor, and has opened a new road for next-generation consumer and industrial electronic products. EP9315 features an advanced 200 MHz ARM920T processor, and supports Linux, Windows CE and many other memory management unit of embedded operating system. TI's TMS320DM642 is the launch of a new fixed-point programmable DSP suitable for multimedia applications, TMS320C64x nuclear, using the same architecture of TMS320C6000 and a high-performance, advanced long instruction kernel.

Taking advantage of the characteristic of a dual-processor, some functionality of the video monitoring system is divided into modules, equitable distribution on two processors running, thus effectively improving system performance. To this end, the design takes a certain division of labor policy, running embedded Linux operating system and some applications software on EP9315. TM320DM642 is responsible for video data encoding, video capture and display. Between two processors, a host interface HPI of DM642 is used for data communication, coordinating the various operations, so as to achieve the purpose of making better use two chips operating in parallel. Concrete realization of the principle of the design is shown in Figure 1.

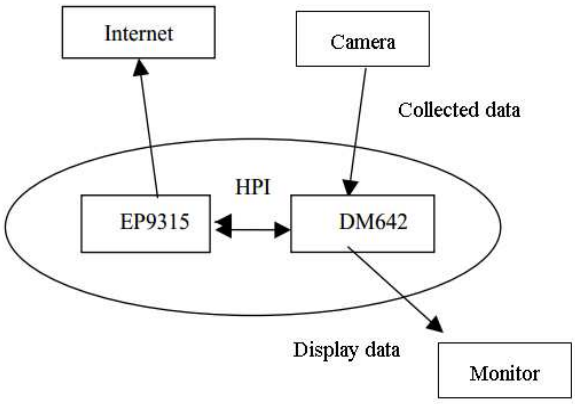

Figure 1 Video monitoring system schematic

Video capture terminal uses a decoder chip TW2814, the video chip provides the external I2C bus control interface. Due to EP9315 chip without I2C controller, the system is connected to the video chip TW2814 by EP9315 GPIO pin, then using these two GPIO port to simulate the I2C controller, and sending a control signal to the video chip. Through access to EP9315 interrupt pin, TW2814 makes the system achieve video loss detection function.

3 The software architecture of embedded video monitoring system

As the embedded video monitoring system requires a strong network transmission and many other sophisticated features, in this paper, the system chooses Linux as the operating system on the ARM processor EP9315. Linux opened kernel source, combining with ARM architecture processor, can play Linux systems' advantages of supporting a variety of network protocols and existing multi-process scheduling mechanism, so that shorten the development cycle, scalability enhancements[4].

The DM642 uses DSP / BIOS, simple embedded operating system provided by TI, which itself occupies only minimal CPU resources. DSP / BIOS provides the underlying application program interface, which can be achieved mainly by invoking a series of DSP / BIOS real-time database API functions. From a functional perspective, the system consists of the following modules: video capture module, video encoding module, data transmission module, network transmission module, the video display module. The relationship between the various modules:

DM642 video data acquisition module runs and collects data into the memory of a good address space by encoding module out of the data collected and packed into the other one for encoding the specified address space. In the data transmission module, EP9315 reads encoded data interface via HPI, and then stores data on the hard drive by the storage module or sends video data to the network by the network. So users can monitor real-time images through a Web browser. The video display module is a separate module from other modules for displaying monitoring video. The relationship between the various modules is shown in Figure 2.

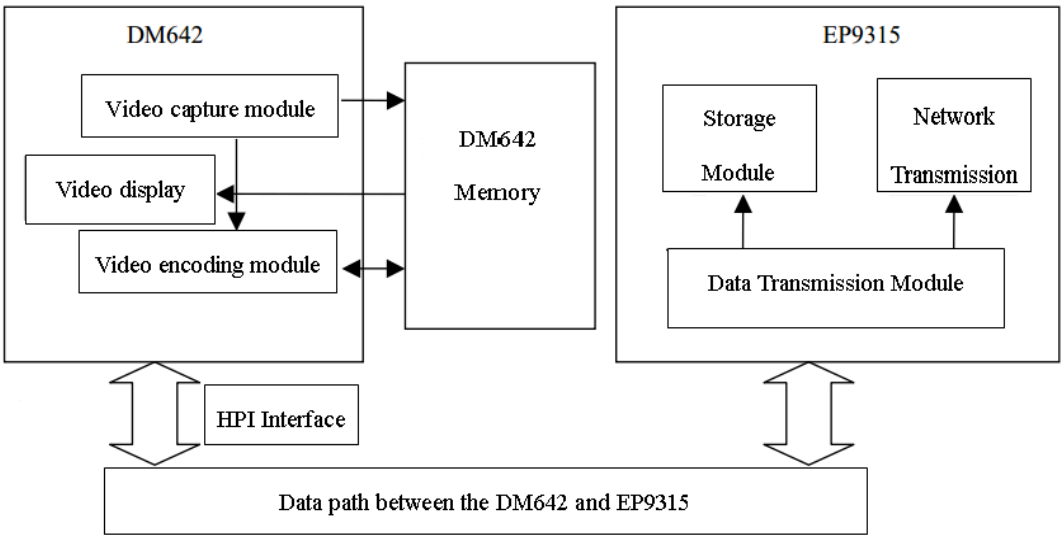

Figure 2 Software module diagram

Video capture of the system is done by video chip TW2814. TW2814 converts the input analog signal into a digital signal. The DSP digital signal acquisition module is responsible for reading TW2814 conversion. After reading the data from the acquisition memory, the encoding module encodes the data, packing it into the designated memory region for reading. Before coding, the video sequence must first be analyzed, each video object divided from the original image, and then encoded separately for each video object, respectively. Each object has its own shape information, motion information and texture information. The encoded video object is these three kinds of information. Since our entire video sequence is rectangular, there is not the arbitrary shape coding, only the motion information is related to coding and texture information encoded, we use the encoding algorithms associated with the motion compensation and discrete cosine transform associated with texture coding, and quantization, Zig-Zag scanning, variable-length coding algorithms. Data transmission module consists of the driver on EP9315 and applications together. Storage module is running on the EP9315 application, and then reads the data packaged by DM642, analyzing data packets, extracting the video data, and the data stored on the hard disk. Network transmission module, borne by EP9315 applications, is responsible for submitting programmed stream to TCP / IP protocol for network transmission. Video display module running on DM642, sends video data to the D / A converter chip ADV7179, and displays the video on the video monitor.

4 Conclusion

In the system that consists of two processors, data transfer in the two processors is indispensable. Through the HPI port provided by DM642, the read and write operation can easily be implemented. In order to achieve the transfer, HPI driver is programmed. Also, the performance of different interfaces in the driver is analyzed and how to start DSP by using HPI driver is discussed. The system needs the support of graphic system to make users control it conveniently. Therefore, display driver is devised and implemented through extending HPI driver. In this way, users can configure and manage the system through graphic system, increasing the degree of convenience of users' interacting with the system.

A Calibration Method of Binocular Stereo Vision System Based on Halcon

Zhixian Zhang[a], Zhende Zhu[b]
[1]School of Shenyang Aerospace University, Shenyang 110135,China;
[a]zzx_syiae@tom.com, [b]114345098@qq.com

Keywords: Camera Model, binocular stereo vision system, calibration, Halcon.

Abstract. This paper describes the pinhole camera model combined with an area sensor and a regular lens and the imaging model of the binocular stereo vision system. Also a method to determine the internal and external parameters of a camera by transferring the coordinates three times is described. Then a calibration experiment is carried out with the Halcon calibration board which proved the method works. The method mentioned in this paper has laid a good foundation for measuring the size of objects with the binocular stereo vision system.

Introduction

Lately, the machine vision is much more frequently used in the area of industrial measurement because of the influences such as the measuring environment and measuring accuracy. However, in the machine vision, the internal and external parameters can be easily changed. Hence, it is necessary to calibrate the cameras in order to get the 3D information of an object. The calibration refers to set up the correspondence between the pixels in the image and the points in the real world. The way is calculating the parameters by the known point's image coordination and world coordination based on the camera model [1].

Currently, the camera calibration methods can be divided into three categories: traditional calibration, self-calibration and the calibration based on active vision. The traditional calibration works by photographing an object in exactly known size and get the camera's internal and external parameters in a series of calculating. Self-calibration works by the relationship between multiple images instead of a known object as the reference. The calibration based on active vision works by moving the camera in exact moving parameters to get multiple images and calibrate with the moving parameters and the images [2-5].

Camera Model. To calibrate a camera, a model for the mapping of the 3Dpoints of the world to the 2D image generated by the camera and lens is necessary. Two different types of lenses are relevant for machine vision: regular and telecentric lenses. Regular lenses perform a perspective projection and telecentric lenses perform a parallel projection. Furthermore, two types of sensors need to be considered: line sensors and area sensors. This paper established a pinhole camera model consisted of area sensors and regular lens, as shown in Fig.1. Four coordinate systems are shown in the figure: the world coordinate system (WCS)(x_w,y_w,z_w), the camera coordinate system (CCS)(x_c,y_c,z_c), the pixel coordinate system (PCS)(r,c) and the image coordinate system (ICS)(u,v). Here, s_x and s_y are scaling factors, and they represent the horizontal and vertical pixel pitch on the sensor. The point P_w in the WCS is projected to the point p in the image plane by the projection center. If there were no lens distortions present, p would lit on a straight line from P_w through the projection center, indicated by the dotted line. Lens distortions cause the point p to lie at a different position. The image plane is located at a distance of f behind the projection center. The f is the principal distance here. It is easier to pretend that the image plane lies at a distance of f in front of the projection center, which simplifies many calculations.

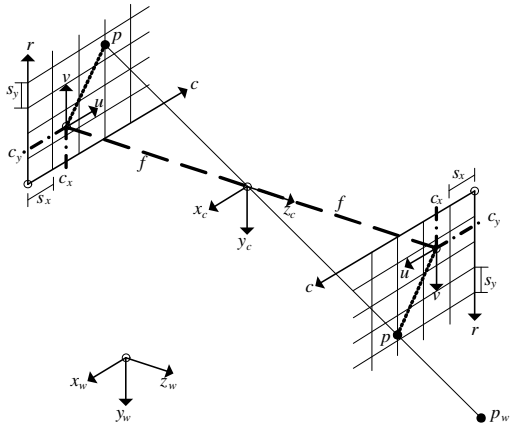

Fig.1 Pinhole camera model

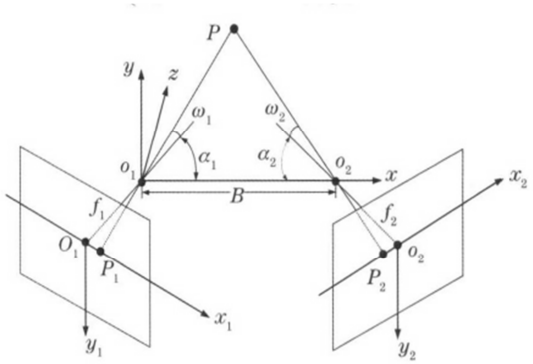

Fig.2 The principle of binocular stereo vision system.

In order to project the point P_w into the point p, three transformations of the coordinate systems are needed:

1. Transform from the WCS to the CCS. The point $P_c = (x_c, y_c, z_c)^T$ in the WCS is given by the point $P_c = (x_c, y_c, z_c)^T$ in the CCS, where $P_c = RP_w + T$. Here, $T = (t_x, t_y, t_z)^T$ is a translation vector and $R = R(\alpha, \beta, \gamma)$ is a rotation matrix, which is determined by the three rotation angles α (around the x axis of the CCS), β (around the y axis of the CCS), γ (around the z axis of the CCS). The six parameters (t_x, t_y, t_z, α, β,γ) of R and T are called the external camera parameters, cause they determine the position of the camera with respect to the world.

2. Transform from the CCS to the PCS. For the pinhole camera model, the projection is a perspective projection, which is given by:

$$(u, v)^T = \frac{f}{z}(x_c, y_c)^T \tag{1}$$

Considering the lens distortions, the coordinates $(u, v)^T$ will be modified. For most lenses, the distortion can be approximated sufficiently well by a radial distortion, given by:

$$(u', v')^T = \frac{2}{1 + \sqrt{1 - 4k(u^2 + v^2)}}(u, v)^T \tag{2}$$

The parameter k models the magnitude of the radial distortions. If k<0, the distortion is barrel-shaped; while k>0, it is pincushion-shaped. This model has a great advantage that the distortion correction can be calculated analytically by:

$$(u, v)^T = \frac{1}{1 + k(u'^2 + v'^2)}(u', v')^T \tag{3}$$

3. Transform from the PCS to the ICS. This process is given by:

$$(r, c)^T = \left(\frac{v'}{s_y} + c_y, \frac{u'}{s_x} + c_x\right)^T \tag{4}$$

Here, the point $(C_x, C_y)^T$ is the principal point of the image. The six parameters (f, k, S_x, S_y, C_x, C_y) are called the internal camera parameters, cause they determine the projection from 3D to 2D performed by the camera.

The principle of binocular stereo vision system. As shown in Fig.2, the binocular stereo vision system is based on the principle of parallax, and get the 3D information of the observing object by two cameras. Here, we pretend the ICS of the two cameras are $O_1 - x_1y_1$ and $O_2 - x_2y_2$, and the point p is projected into p_1 (x_1, y_1) and p_2 (x_2, y_2), with the points o_1 and o_2 being the principle points. We set up a measuring coordinate system (MCS) $O - xyz$ with the point o_1 as the origin and the point p located in the plane $O - xz$. The line o_1o_2 is named the base line, with the length B. If the focuses of the cameras are f_1 and f_2, the angles between the axis x and light axis O_1o_1, O_2o_2 are

α_1 and α_2, and angles between the lines through the principle points and the point p and the light axis are ω_1 and ω_2, then we can get the coordinates of the point p in the MCS:

$$\begin{cases} x = \dfrac{B\cot(\omega_1+\alpha_1)}{\cot(\omega_1+\alpha_1)+\cot(\omega_2+\alpha_2)} \\ y = Y_1\dfrac{z\sin\omega_1}{f_1\sin(\omega_1+\alpha_1)} = Y_2\dfrac{z\sin\omega_2}{f_2\sin(\omega_2+\alpha_2)} \\ z = \dfrac{B}{\cot(\omega_1+\alpha_1)+\cot(\omega_2+\alpha_2)} \end{cases} \tag{5}$$

Where ω_1 and ω_2 can be get by:

$$\begin{cases} \omega 1 = \arctan(X_1 / f_1) \\ \omega 2 = \arctan(X_2 / f_2) \end{cases} \tag{6}$$

The experiment of the binocular stereo vision system.

The calibration board. The calibration needs enough coordinates of the points in the WCS, so in here we can use a calibration board which is exactly measured and movable. There are 49 points in the board and a black triangle located in one of the corners in order to determine the direction.

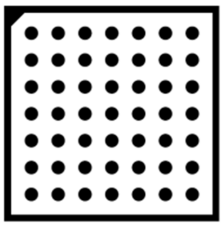

Fig.3 The calibration board

Fig.4 The experiment platform

Set up the experiment platform. We use two cameras MER-130-30UM-L, with the port USB 2.0, and the parameters is provided in the Table 1:

Table 1 The parameters of the cameras

Type	MER-130-30UM-L
Resolution	1280x1024
Pixel size/μm	5.2 x5.2
Spectrum	Grayscale

The experiment platform is shown in the Fig.4:

The experiment results. We need the two cameras shoot images of the calibration board at the same time, and the board is required to be complete in all of the images. In every experiment, we got 30 groups of images, 5 of them is shown in Fig.5:

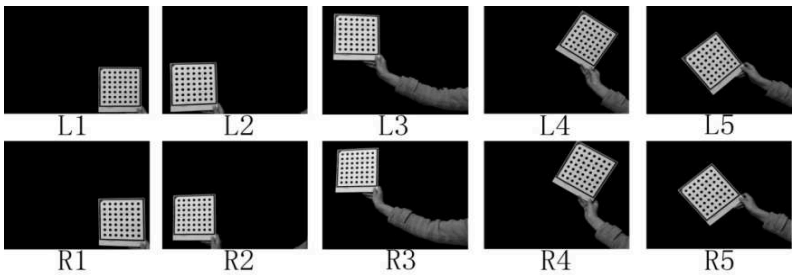

Fig.5 Several images for calibration

The experiment results are provided in Table 2 and Table 3:

Table 2 The results of internal parameters

	$f(mm)$	$k(1/m_2)$	$S_x(\mu m)$	$S_y(\mu m)$	$C_x(pixels)$	$C_y(pixels)$

Summary

This paper introduces the principles of the calibration and the binocular stereo vision system, and operated the experiment with the error in 3mm, which proved that the method is feasible. The method mentioned in this paper has laid a good foundation for measuring the size of objects with the binocular stereo vision system.

The brief introduction of several common subway shock absorber fasteners in china

Huapeng Luo[a], Dunjin Cai[b], Mingliang Liu[c] and Ping Wang[d]

MOE Key Laboratory of Highspeed Railway Engineering, Southwest Jiaotong University, China

[a]756468322@qq.com,[b]1198876623@qq.com,[c] 1282135564@qq.com,[d]wping@home.swjtu.edu.cn

Keywords: subway shock, shock absorber, fasteners

Abstract. Due to the large and medium-sized cities in our country is more; the urban rail speed is low and the environmental protection high capacity requirements. Each city urban rail structures more or less differences. Especially fastener system is various, even in the same line also exist different deduction system; Because the subway in China fastener system is various and not a fixed is widely used fastener system; The paper gives a simple summary of subway common shock absorber fasteners in China. I hope it can give a reference to researchers on fasteners.

Introduction

The fastener system is a connection of rail and sleeper . The fastener system has its important role in the track. Urban rail transit in China has been vigorously developed in decades. The urban rail transit has the characteristics of the short circuit, the low speed, the high demand in noise reduction and environmental protection, etc. But, on the whole, all kinds of new fasteners are based on the research and development of several typical fasteners. The paper gives a simple introduction of common shock absorber fasteners system in our nation.

LORD damping fasteners

The main structure of fastener which is designed by LORD Company is sandwich-type cementation and metal plate. As is shown in figure 2.Its main characteristics are vulcanizing supporting rail plate, perforated rubber and base plate to achieve a whole, making use of the deformation of rubber hole to achieve vibration reduction. LORD fastener directly supports rail track, sets up the plate which adjusts the height . LORD fastener has been used in 4th subway routes line of Guangzhou.

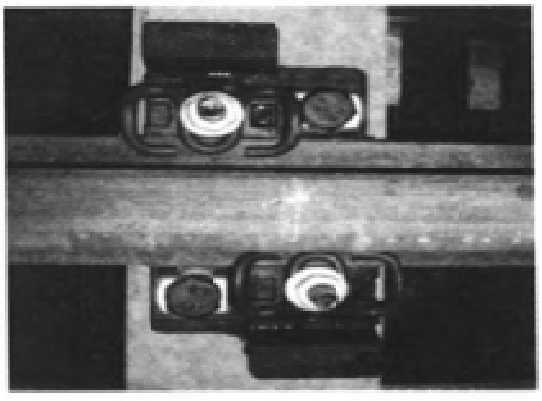

Fig.1 LORD Vibration fasteners

LORD damping fastener has characteristics of integrated design, perfect integrity, the appropriate structural height which consistent with the existing line, the track vertical subsidence which is less than 1.5 mm, meeting requirements for the technology of linear motor, etc.

2 Shock absorber fasteners (cologne egg)

With reference to foreign information on track shock absorber and other domestic shock absorber and characteristic of subway track structure, the shock absorber is usually designed as elliptic cone to avoid stress concentration. As is shown in figure 2, it can effectively reduce vibration energy of track to achieve the effect of damping and buffering. Damper fastener is a separated shoulder fastener which is designed as elliptic cone. The elliptic cone bonds inner ring and outer ring with rubber vulcanizates. Its vibration reduction effect is remarkable. Shock absorber buckle has a large deflection under wheel-load, reducing the mechanical impedance of the upper buildings and vibration excitation. It uses rubber shearing deformation to attain high elastic vibration reduction.

Rail vibration absorber fasteners are a widely used transit damping products in urban rail. Beijing, Shanghai, Guangzhou and other cities have been successfully used it in subway lines.

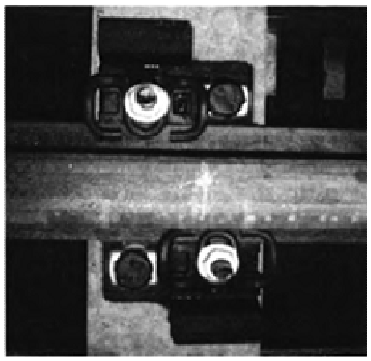

Fig.2 Absorber fastener

3Ⅰ type shock absorber on the rail fastener

Beijing urban construction design & research institute researched and designed the Ⅰ type shock absorber on the rail fastener as early as 1988, then it applied for patent (figure 3). Its structural characteristics is using rubber ring which vulcanizes sleeper rail supporting iron plate and the iron plate under the base of rail in a body to withstand shear effect [2]. Because its shear elasticity is better than that of the compressive elastic rubber, rail damper fastener has very low vertical static stiffness, generally in 10 ~ 18 KN/mm.

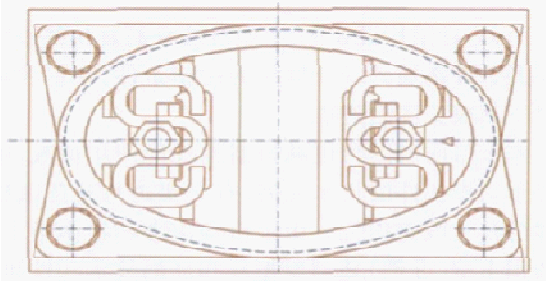

Fig.3 Ⅰtype rail absorber fastener

Ⅰ Type shock absorber on the rail fastener which is applicable to 60 kg/m rails based on the design concept of "egg" cologne in Germany, which is a rectangular base plate, Its connection of rail plate supporting and the base is oval. It is an open fastener without retaining shoulder has a

lower vertical static stiffness (generally in the 10 to 18 KN/mm). The product passed the scientific and technical appraisal of Shanghai in 1990 laid in Shanghai metro line 1, 2. The rubber ring which is made from domestic neoprene attains material formula from product manufacturer .According to the research report of Ⅰ type shock absorber on the rail fastener, the laboratorial detection performance of first generation rail shock absorber is good. It has a good damping effect, its fastener vibration acceleration level decreases by 10-20 dB compared with DT Ⅲ type. In the use of Shanghai metro line 1, its early damping effect is obvious, playing an important role .It fills in the blank of no shear fastener the our country that only has compression type fastener.

4 Ⅱ type orbital damper fastener

Ⅱ type shock absorber on the rail fastener develops from Ⅰ, mainly adjusted withhold rail parts, apply to 50 kg/m rails. it is without retaining shoulder open elastic fasteners.

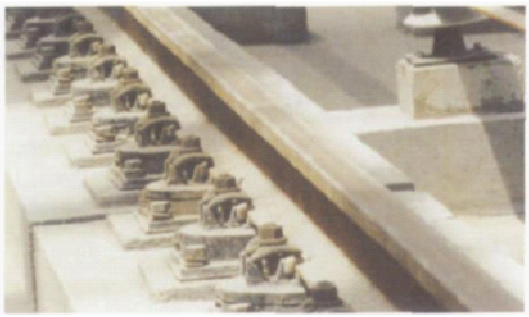

Fig.4 Ⅱ type orbital damper fastener

5 double stiffness Ⅲ orbital damper fastener

Double stiffness Ⅲ orbital damper fastener is a new type of subway track damper fastener which develops from Ⅰ(Ⅱ). The gauge for adjustment amount is: + 8 ~ -12 mm; Rail horizontal adjustment quantity as follows: under the rail allows up to 10 mm, vibration isolator allows up to 20 mm. The rail dynamic subsidence limit take 3 mm; Static stiffness is 8 ~ 12 KN/m, output ratio of Q-switching to free running control in the range of 1.2 ~ 1.25, Stiffness design for double stiffness, the first stage stiffness is also known as stiffness, damping significantly improve the effect of the vibration, static stiffness for 8 ~ 12 KN/mm. Stiffness is also known as the second order safety stiffness, static stiffness control the order in 25 ~ 40 KN/mm, guarantee the necessary support stiffness of which the change of rail geometry in the safety of the allowable range. Withhold with no bolt elastic condition, no bolt e shaped article, facilitate the subway all play in the form of a unified, improve the adaptability of fasteners. Double stiffness Ⅲ orbit damper fastener as shown in figure 5. The vertical load of 15 ~ 35 KN, horizontal lateral load is 10 ~ 20 KN, within the scope of the load vibration and exert effective.

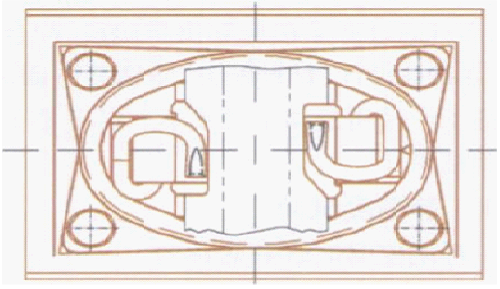

Fig.5 Ⅲ type track vibration isolator fasteners

6 GJ - Ⅲ damping fasteners

GJ - Ⅲ double nonlinear damping fasteners is no block separated shoulder type elastic fasteners, mainly used in Guangzhou metro. The fastener for compression damping fasteners, its static stiffness is 10.94 KN/mm, dynamic and static stiffness than < 1.3. GJ - Ⅲ type double nonlinear damping fasteners develops from the bottom plate type fastener system , on the basis of the design of double nonlinear elastic plate system, reduce the system stiffness, improve the damping of structure, and effectively reduce the secondary noise and vibration. As is shown in figure 6, it constitutes rubber mat under the rail, fen plate and rubber pad in the middle, the iron plate and self-locking mechanism. Low stiffness system reduces the vibration transmission of its supporting system, so as to reduce the spread of the ground vibration. The unique "self-locking structure" is a big window. It can be very convenient to connect the component, greatly reduces the maintenance cost. On the whole, GJ - Ⅲ fastener is compact size, relatively light, height 60 mm, using polyethylene as the material of high plate, adjust static stiffness of plate greater than1000 kN/mm, which has no effect on the system stiffness.

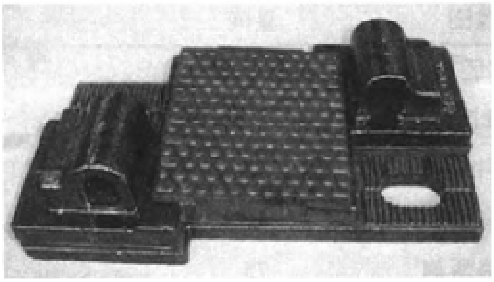

Fig.6 GJ - Ⅲ double nonlinear damping fasteners

Conclusion

In this paper, several common fasteners of the subway are made a brief introduction and it give a reference to researchers. Our metro fastening system complicated, since there is no uniform standard, mostly do part research on existing fastening systems; various research units of their research are relatively conservative and cannot brainstorming developed a widely accepted fastening systems. I hope the relevant departments to organize our research unit jointly develop suited to China's national conditions, with our own intellectual property, can be widely used the subway damping fastening systems.

Design of the Improved Accompanying Temperature Logger

Juan GUO[1,a], Shiying Liang[1,b] and Zongtao Yin[1,c]

Shijiazhuang Vocational Technology Institute, Shijiazhuang 050081, China;
[a]juanguoluck@126.com, [b]liangshy@mail.sjzpt.edu.cn, [c]yinzt@ mail.sjzpt.edu.cn

Keywords: Power consumption; Temperature measure; Logger; Low power

Abstract: This paper describes research on some methods of reducing power consumption to reduce the volume accompanying logger. For the requirement of ultra-low power consumption and miniature, the design is described separately from the hardware and software, mainly including temperature detecting module, interface of communication, low current circuit hardware, energy conservation ,arouse from power down state, communication protocol, etc. The experimental tests for device prove that the research can achieve low power requirements.

Introduction

In the course of the different stages of production, transportation and storage of chemical, food, medical and other products, in order to ensure the best quality products, continuous tracking temperature is critical. Currently accompanying logger and power consumption are large volume, high cost, which limits its extensive use. Therefore, a small volume of low-cost and long-time continuous measurement of micro-recorder, compact and easy to carry, is needed.

Therefore, the paper starts two studies of the volume miniaturization and micro-power and designs a micro recorder whose volume equivalent to only several coins stacked together, and the recorder can be attached to the surface of the object, along with objects placed inside the bag.

Since October 2012, the recorder has been formally put into production, Asia Brewery Xinxiang, Hunan Seven Swords Beer Company and other units have used the product to record the pasteurization temperature with favorable results and some promotional value.

1 The working principle of the temperature recorder

Temperature sensor measures the ambient temperature and transfers to the microprocessor for temperature signal processing, and the compressed data stored in the internal RAM, the data read out by the computer[1].

A temperature sensor is placed in a stainless steel shell and has good heat conductivity with the inner wall, which can be sensitive to the temperature of inner wall. The shell is made of stainless steel, communication by the housing, and without communication interfaces, long-term work in a variety of harsh environments where liquids or acid, communication with a computer, controlling the recorder, through the interface circuit.

The recorder's temperature range of -40 ℃ ~ + 85 ℃, temperature resolution of 0.0625 ℃, measurement accuracy of ± 0.2 ℃, it can record 4K data, and recording interval can be set discretionarily, inside lithium battery life> 5 years.

2 The miniaturized design of logger circuit

2.1 Temperature measurement and conversion mechanism

The miniaturized design not only reduces circuit board area, but also reduces the power consumption and ensures the accuracy of the measurement, not the traditional temperature

measurement and conversion circuit. The digital temperature sensor DS620 by Maxim can 1.7V-3.5V voltage, -55℃-+125 ℃ working temperature down to 10 to 13 precision output temperature values at 0℃-+70 ℃, maximum error ≤ ± 0.5℃, corrected measurement accuracy can be improved to ≤ ± 0.2 ℃. Small, its μSOP package only 5 × 3mm, very consistent miniaturization requirements[2].

According the error statistics graph of DS620 in the range of 0-70 ℃, making its Mean polynomial curve to get the formula between error Δ t ' and the measured value t:

$$\Delta t' = 0.0002(t/10)^3 + 0.0148(t/10)^2 - 0.1566t/10 + 0.3479℃$$

In the formula, t is the measured temperature, Δt' is t Mean deviation of the curve. The actual offset calibration error Δt", the total error correction Δt = Δt' + Δt", to improve the measurement accuracy of the DS620 ≤ ± 0.2℃.

2.2 Based Mega328P recorder core circuit

In the miniature, the core circuit is only a 5 × 5 × 1.0mm QFN package and small resistive and capacitive components of Mega328P, DS620 and several pieces of 0420, using micro SMD 32.768KHz crystal. Use FPC circuit board, circuit board logger overall thickness not exceeding 1.8mm. Circuit diagram is shown in Figure 1.

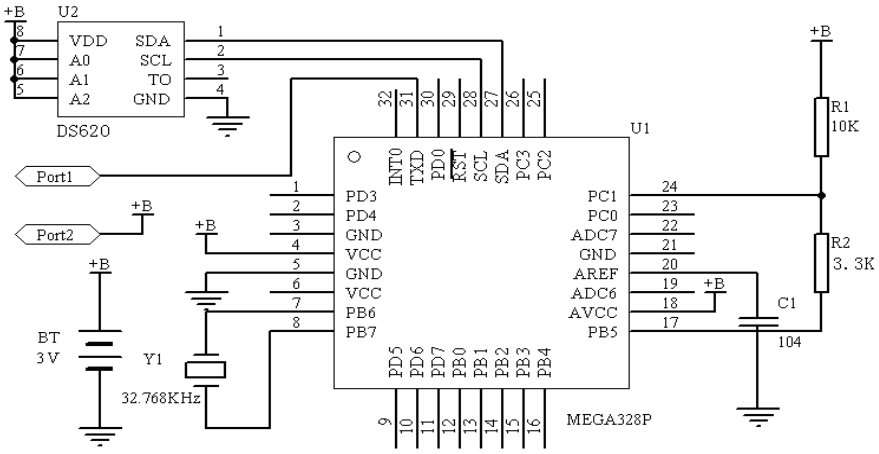

Fig.1 Logger core schematic

Here, DS620 converts the measured temperature to 10-13digital bits transmitted through the I2C bus to Mega328P[3], the data compressed is stored in 2K bytes of RAM, the resistors R1 and R2 are the battery voltage measurement circuit, PB5 low usually, R2 to ground, the battery voltage is obtained by the ADC; PB5 output high, reducing the current consumption of R1 and R2. Chips waked and communications are done via TXD pin, in order to adapt to work in a conductive liquid, the battery positive as ground, so even if the electrode of communication and the shell are shorted , which will not have impact on Mega328P.

3 Logger software energy-saving design

3.1 Logger Software Process

Temperature logger software adopts modular design, including single-chip power-on initialization, system timing, command parsing, temperature measurement and recording, communication, etc.

System after power-up, power-down state to enter (turned off). Only Mega328P external interrupt can wake it up from power-down state. Use of certain external interrupt consisting of command sequence: If you receive a boot command, the system self-test, self-test by entering records state. Sleep when not sampling, only the timer work. When the sampling time, to exit hibernation, temperature sampling, data recording, and then re-enter hibernation; If you receive a

communication command, then stop recording, the recorded data is transmitted to the computer via the interface circuit. Communication over, enter the power-down state again.

3.2 Serial software simulation

Given Mega328P not working in a power-down state, only the external interrupt can wake it up, so take advantage of MCU pin interrupt function to simulate a receiver serial port. Via 328P hardware serial communications to send large amounts of data, TXD pin also receives external commands. TXD pin is usually set as input, active low enable external interrupt. TXD pin by pulling 100ms, wake Mega328P. After the wake 328P, the TXD falling edge interrupt mode is set to trigger at the same time start the timer T0 interrupt interval timer for TXD. Command, nine consecutive falling edge pulse, is sent to the 328P, the first pulse T0 timing synchronization , following 8 pulses are the communication of information , low on going 1ms to "0", 2ms to "1"[5]. TXD pin waveform is shown in Figure 3.

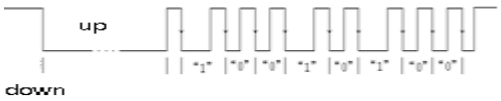

Fig.3 TXD Pin wave chart

When the logger outside communication, the TXD pin is set to output to enable hardware serial communications and close its external interrupts. After the communication, TXD low level triggers external interrupt, waiting to receive another frame command.

3.3 Software micro-power design

Recorder energy devices primarily are MCU Mega328P and DS620. Mega328P operating current has a great relationship with its operating mode, when IDLE, the operating current is only about 15% of ACTIVE current, full use of IDLE can reduce the operating current. The main factors affecting the Mega328P operating current is the clock frequency, reducing the clock frequency can greatly reduce the operating current[4]. Due to the speed of AVR MCU 1MIPS/MHz, using low frequency 32.768 KHz crystal can meet the computing speed. Such Mega328P at 3V ACTIVE state current consumption is 60μA, IDLE state current of 10μA, the power-down state current is less than 1μA. DS620 temperature conversion work when current is 0.8mA, when not converting less than 1μA, conversion time and is proportional to conversion accuracy, the resolution of 0.5 ℃ conversion time is 25ms, 0.0625 ℃ time is 200ms. Current Logger is calculated by the formula (2).

$$I = \Sigma I_i T_i / \Sigma T_i \quad (2)$$

Here， under certain state operating current Ii, μA; the state duration Ti, ms. At a resolution of 13, a temperature of the collected per minute.

Working state	Duration (s)	Operating current (μA)
IDLE	59.97	10
ACTIVE	0.01	60
Sample	0.02	800

The average current

$$I=\Sigma I_i T_i/\Sigma T=(10*59.97+60*0.01+800*0.02)/60=10.27\ (\mu A)$$

4 The experimental results

Experimental tests were carried out for the design of low -power and accuracy. In 0℃ice-water mixture, carrying out at a temperature above 10 ℃ oil bath at test temperature. The measurement results are shown in Table 1.

Tab.1 Error experimental data

No.	Standard Temperature	Original error	Correction error
1	0.0℃	-0.3℃	-0.1℃
2	20.0℃	- 0.2℃	0.0℃
3	40.0℃	-0.2℃	0.0℃
4	60.0℃	-0.1℃	0.0℃
5	80.0℃	-0.2℃	0.1℃

By contrast, it is found that the temperature error after correction ≤ ± 0.1 ℃, reaching ≤ ± 0.2 ℃ design requirements. As the overall power consumption is closely related to the sampling and recording interval accuracy, precision experiments at 13 intervals of one minute recording conditions, with Agilent34401A logger to measure the operating current. Since the operating current cyclical and jump, use the capture function 34401A peak and measure overall maximum current 856.3μA, minimum current of 9.6μA, the average current is 11.5μA, and theoretical calculations are consistent. Such a capacity of 450mAh battery records once per minute, continuous measurement time 54 months, about 4.5 years , power consumption meets the design requirements.

5 Conclusion

The miniature and low-power design of accompanied temperature logger reduces the volume, power consumption, enabling miniature recorder to work longer. While using unique stainless steel shell structure, the recorder can work reliably under complex situations in a variety of fields. And its miniaturization and energy efficient design also provides a reference for designing other similar electronic devices.

Coiling Tension Control System of PID Simulation

Zhongchu Wang[a], Yuan Ding[b],Hongyang Zhao[c] and Xiaodong Hu[d]

University of Science and Technology Liaoning, Anshan 114051, China

[a]wangzhongchu01@126.com, [b]ding00yuan@163.com,[c]zhy@ustl.edu.cn,[d]hulinas@sohu.com

Key words: coiler; tension control; traditional PID; simulation

Abstract. Coiling tension control system is the main control means to ensure the quality of the rolling process. According to the characteristics of coiling tension control characteristics and the requirements of actual engineering, establish the mathematical model of the double closed loop control system and use the traditional PID to tuning the model parameters. It is proved by Matlab simulation experiments that traditional PID can effectively improve the response process of coiling tension control system and greatly enhance the dynamic and steady-state performance.

Introduction

The coiling is an important process of cold rolling production process, can realize the rolling with tension. Its control accuracy directly determines the quality of the final product. Tension control system is one of the widely used in modern industrial control systems[1].In the process of rolling, the stability of coiling tension has great effect on adjusting the shape, thickness control and the quality of the products, also can prevent the work piece deviation phenomenon. Therefore, the tension control is a very important link in the control system of cold rolling mill.

The PID control is integrated control method based on the deviation of proportional, integral and differential. It has many advantages of simple principle, easy realization, robustness, wide applicability and also can improve dynamic and steady-state characteristics of the system. As long as the correct setting its parameters can realize its control function, so it is widely used as a controller applied to the tension control system[2].In this study, six roller cold rolling machine used is based on indirect constant tension control of torque control and compensation control. We establish the main mathematical models, tune parameters and use traditional PID control algorithm to simulate of the model. It improves the control precision and provide a strong guarantee for obtaining good shape and gauge control results.

Tension control principle and system structure

The system used is based on indirect constant tension control mode of constant linear velocity without tension detection feedback you can get more stable tension control effect，and also use speed loop and current loop of double closed loop cascade speed regulation system.In the process of speed control, the speed loop finally finishes speed regulation by adjusting the torque to control the current.In the process of tension control, the speed regulator is saturated,and adjusts the output torque of the motor by controlling the current limit value to achieve the constant tension control[3].

According to the literature[5],Coil winding characteristic of motor is:

$$M_D \cdot n = \frac{v_2 i}{2\pi} \cdot T = K \cdot T \tag{1}$$

In the process of coiling, the size of the tension is generated by the motor output torque, and is represented by the armature current I_a of the motor.Motor torque is:

$$M_D = C_m \phi I_a = M_T + M_O \pm M_d = \frac{TD}{2i} + M_O \pm M_d \tag{2}$$

Formula, M_D is the output torque of the motor, $N \cdot m$; M_T is the establishment of

tension torque tension required, $N \cdot m$; M_O is no-load torque, $N \cdot m$; M_d is dynamic torque required for acceleration and deceleration, $N \cdot m$; T is tension, N; n is coiling motor speed, $r/\min$; v_2 is reel line speed, $m/\min$; K is constant; D is reel diameter, m; i is reduction ratio; ϕ is motor flux, $\times 10^{-8} Wb$; I_a is armature current of motor, A; C_m is structure constant of motor.

When coiling machine stably works, in order to ensure the constant tension, it needs to maintain a constant speed winding. $M_d = 0$,ignore the no-load torque.So the tension is:

$$T = 2C_m i \frac{\phi I_a}{D} = K_m \frac{\phi I_a}{D} \tag{3}$$

It is seen from formula(3),as long as the guarantee of I_a is proportional to $\frac{D}{\phi}$,it can keep constant tension and make full use of motor power and to obtain the maximum output torque,namely maximum torque method.

Real-time volume diameter is calculated using the indirect method of calculation and usually uses the speed ratio, the basic formula is:

$$D = \frac{v_1}{\pi n} \tag{4}$$

Formula, v_1 is strip line speed, $m/\min$; n is coiling motor speed, $r/\min$; D is reel diameter, m According to the principle of the indirect tension control,tension control system is actually the process given its conversion into a motor torque current value,to control the coil current for limiting, is to control the current of the motor winding machine.Indirect coiler constant tension control system structure is shown in figure 1.

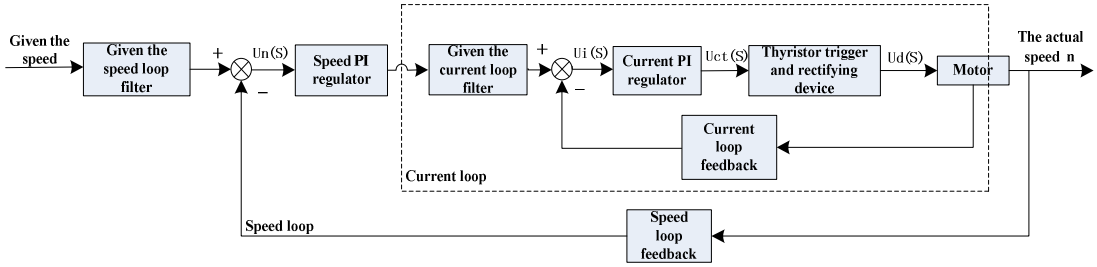

Fig. 1 Structure block diagram of double closed loop speed control system

Mathematical models

Tension dynamic mathematical model. In the actual rolling process, the reason why there is tension rolling effect is due to the presence of a speed difference in the longitudinal direction of the rolling member so that the relative displacement in the rolling of metal to produce the different parts of the tension[4].According to Hooke's law, the strip coiling tension is:

$$T = \frac{\delta E}{l} \int_0^{t_1} (v_2 - v_1) dt \tag{5}$$

Formula, δ is strip section area, m^2; E is the elastic modulus of strip; l is the distance between the reel and the work roll, m; t_1 is time to build tension winding mechanism, $\min$.

In the actual production, v_1 is constant,and to maintain a constant tension, it should ensure $v_2 - v_1$ constant.Namely reel line speed is constant and coiling motor speed increases with the volume but inversely proportional to the diameter decreases linearly.According to the literature[5],through the relationship between tension T and speed v, after calculation, the transfer function is obtained:

$$G(s) = \frac{T(s)}{\Delta v(s)} = \frac{K_t}{T_t \cdot s + 1} \tag{6}$$

Formula, T is tension, N ; Δv is reel and work roll on the surface of the linear velocity difference, $m/\min$; T_t is the time of establishment tension, $\min$.

The mathematical model of the coil motor. The motor is used in DC separately excited motor, through the derivation of the relation between input and output that voltage and current,torque and speed of winding motor,according to the literature[5],we can get the transfer function of the motor:

$$W(s)=\frac{n(s)}{U_d(s)}=\frac{1/C_e}{T_m T_l s^2+T_m s+1} \tag{7}$$

Formula, C_e is DC motor EMF constant; T_m is electrical and mechanical time constant of electric drive system; $T_l=\frac{L}{R}$ is the armature circuit of electromagnetic time constant.

Thyristor trigger and rectifying device model. Rectifier link system consists of a thyristor trigger and rectifying device[6],in the project it can generally be considered to be a first-order inertia link.The input is the control voltage trigger circuit U_{ct} , the output is the output voltage transmission device U_d ,from the literature[5],we can get its transfer function:

$$\frac{U_d(s)}{U_{ct}(s)}=\frac{K_s}{T_s+1} \tag{8}$$

Formula, K_s is rectifier links magnification; T_s is thyristor maximum time out of control,thyristor rectifier lag time constant takes 0.0017s.

The traditional PID control

PID algorithm. PID control is a controller that is based on the system error,and use proportional, integral, differential controller to calculate a control amount for control.In engineering practice, the traditional PID control is the most widely used control algorithm, which has the advantages of simple structure, good stability, easy parameter adjustment.In practice,there are PI control and PD control[7].The conventional PID control system block diagram is shown in figure 2.

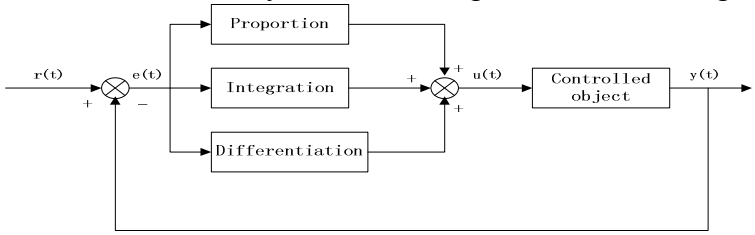

Fig.2 Block diagram of the PID control system

The differential equation of PID regulator is:

$$u(t)=K_p\left[e(t)+\frac{1}{T_i}\int_0^t e(t)dt+T_d\frac{de(t)}{dt}\right] \tag{8}$$

The transfer function can be represented as:

$$G(s)=\frac{U(s)}{E(s)}=K_p\left(1+\frac{1}{T_i s}+T_d s\right) \tag{9}$$

Formula, $u(t)$ is the output of the controller; $e(t)=r(t)-y(t)$ is the deviation input of the controller; K_p is proportional coefficient; T_i is integral time constant; T_d is differential time constant.

The parameter setting based on the conventional PID regulator. In the winding process, in order to ensure a constant tension, the system has two controllers.The one is the current controller the role of which is in the roll diameter increases the moment of inertia by dynamically compensated control current to perform dynamic compensation system to ensure constant tension;the other is the speed controller that is to control the speed v_2 of motor winding and makes v_2-v_1 constant to ensure

constant tension.In parameter tuning process of both regulators, we assume that parameters of the system is unchanged, according to the state when an empty roll winder design speed control system.

The static characteristics of PI regulator is:when the saturated output reaches the limit, the output is constant and the output is not affected by the impact of the input;when the regulator is unsaturated, the role of PI is to make the input offset voltage in the steady state be always zero.Therefore,the final fluctuations when the steady state of tension is zero.The controller design is achieved according to the PID control mode.According to the actual requirements of the system, the current loop in sudden control hopes no overshoot amount or as small as possible.Therefore,current loop should be corrected into a typical type Ⅰ system, while the control object is a double inertia type.Consequently,current loop uses PI regulator and its transfer function is:

$$W_{LT}(s) = K_i \cdot \frac{\tau_i s + 1}{\tau_i s} \tag{10}$$

In order to make the regulator of the zeros and the controlled object with large time constant pole cancellation, choose the time constant is $\tau_i = T_l = 0.025s$ .The scaling factor K_i depends on the desired current loop cut-off frequency ω_{ci} and dynamic performance index $(\sigma_i\% \le 5\%)$,chooses $K_p T_{\Sigma i} = 0.5$,and gets that:

$$K_i = \frac{T_l \cdot R}{2K_s \cdot \beta \cdot T_{\Sigma i}} = \frac{T_l \cdot R}{2K_s \cdot \beta \cdot (T_I + T_s)} = 1.25 \tag{11}$$

Formula, β is current loop feedback factor, gets 0.0095; T_I is current feedback filter time constant,gets 0.002s;Similarly, in order to maintain constant tension, the system should be no static error, and therefore,it should be corrected speed loop into a typical type Ⅱ system, has a strong anti-jamming ability.Speed loop also uses PI regulator and the transfer function is written:

$$W_{ST}(s) = K_n \cdot \frac{\tau_n s + 1}{\tau_n s} \tag{12}$$

A typical system parameters according to type Ⅱ selection methods are:
$\tau_n = h \cdot T_{\Sigma n} = h \cdot [T_N + 2 \cdot (T_I + T_s)] = 0.087s$ （$h = 5$) .According to the open-loop gain of the speed loop,we obtain proportional coefficient K_n is:

$$K_n = \frac{(h+1)\beta C_e T_m}{2h\partial R T_{\Sigma n}} = 60.98 \tag{13}$$

Formula, α is speed loop feedback factor,gets 0.01; T_N is speed feedback filter time constant,gets 0.01s.

Simulation

The conventional PID coiling tension control system is simulated with Matlab/Simulink software.Since the detection current signals often contain AC component, on the need to increase the low pass filter, but in order to balance the signal delay effect, need to join the inertial filter in the signal given, so as to meet the requirements of design and control.Enter the given value U_n^* of the rotational speed of the set is the step response.Stable speed is $100r/\min$ .The sampling time of the control object is 1s.Mechanical and electrical time constant of the motor is 0.148s.The response curves of the reel drum in empty volume simulation are shown in figure 4 and figure 5.

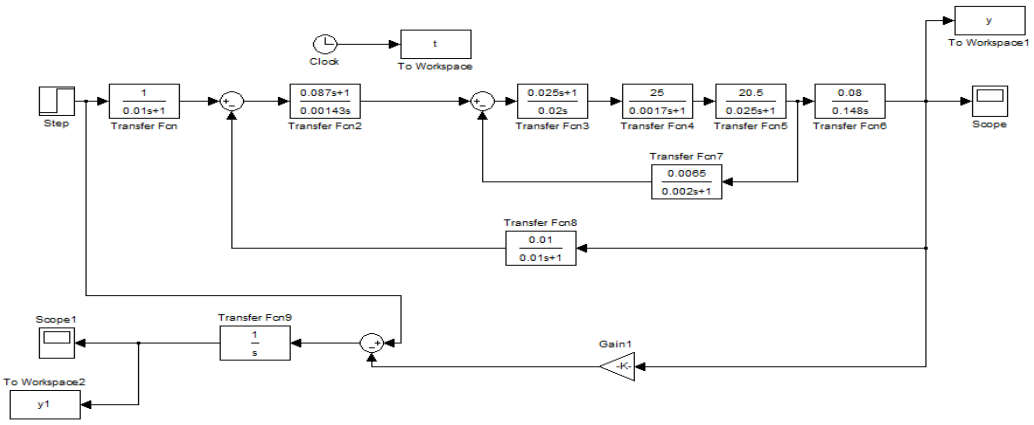

Fig. 3 The system simulation diagram of drum air volume

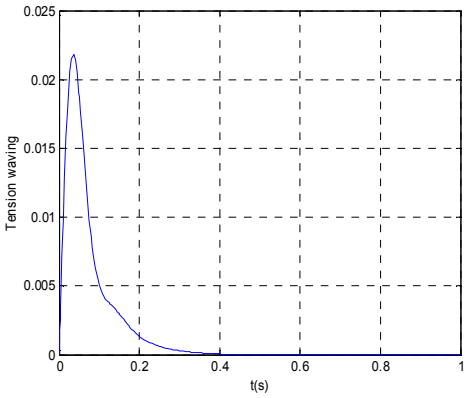

Fig.4 Speed response curve of no-load roll

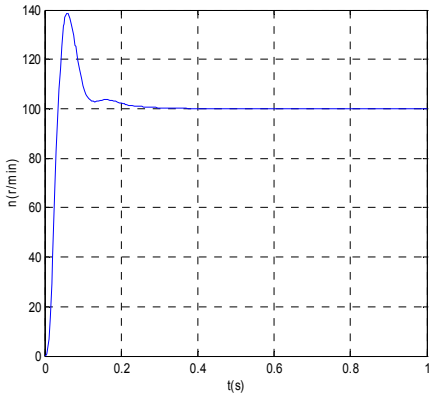

Fig.5 Tension fluctuation figure of no-load roll

Figure 4 shows, according to the typical Ⅰ type system design of current loop has good performance , fast system response and speed stability time t_s is only 0.5s.Speed ring is designed by typical type Ⅱ system , the overshoot of system is 38.7%.The simulation results are in conformity with design setting conditions.According to formula(4), the tension of the strip is produced by $v_2 - v_1$,and when the drive motor speed follow performance is very good, also the corresponding tension fluctuation is small.As can be seen from the figure 5, tension fluctuation amplitude is associated with the speed overshoot and wave time is also consistent with speed settling time at the same time, about 0.5s.After that the speed difference is kept constant, and therefore tension is constant and fluctuation is zero.

As the strip is wound to the drum, electromechanical time constant of the motor is increased.The electromechanical time constant T_m in figure 3 is selected 0.6s,at the same time,the reel is in the coiling process.The control object sampling time is 3s, the response curves of simulation are shown in figure 6 and figure 7.

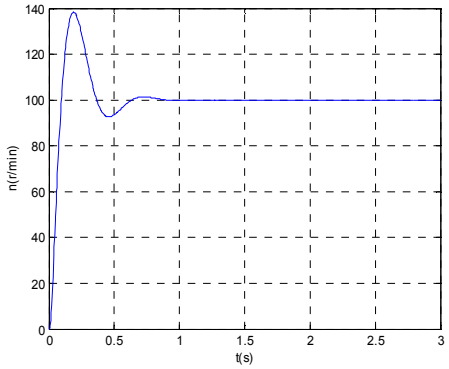

Fig.6 Speed response curve during coiling

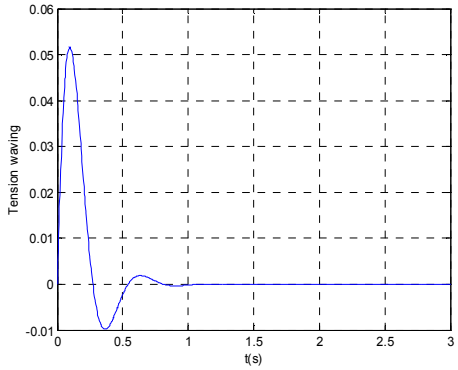

Fig.7 Tension fluctuation figure during coiling

Figure 6 shows,in the process of coiling, speed stability time is 1.4s, the overshoot of the system is 38.3%, the simulation results also meet the design index.Figure 7 shows,tension fluctuation amplitude is only empty volume doubled. Wave time is also consistent with speed settling time at the same time, about 1.4s. Finally, tension is kept constant and fluctuation is zero.Thus, the simulation results demonstrate the traditional PID control in winding tension control can basically achieve good results.

Conclusions

Through the experimental simulation of the coiling tension control system model, it is proved that the traditional PID control has the advantages of fast convergence, small overshoot and good stability.Application in the coiling tension control system improves the control precision, reduces the tension fluctuation and provides the theoretical basis for the production of fine material in practice.

Keywords: Energy recycling, damping force, vibration, efficiency

Abstract. The traditional hydraulic shock absorber suspension converts the vibration energy between the sprung mass and unsprung mass into heat energy. The realization of vibration energy recycling can reduce vehicle's energy consumption, developing ideals for the research of the active suspension/ semi-active suspension. Four kinds of energy reclaiming suspension's structure principle is introduced in detail and the development restricting factors of the suspension at present are worked out through the unified measure, indicating the technology breakthrough points.

Introduction

Suspension system is an important assembly parts of vehicles, and is the transmission and connection device between the vehicle body and wheels. The effect of the suspension system is to moderate and attenuate the impact passed from road to the body, and to ensure the normal running of the vehicle and passenger's comfort. Traditional hydraulic shock absorber suspension transforms the mechanical energy of relative linear motion between sprung and unsprung mass into heat dissipated [1]. If this part of the vibration energy can be recycled and stored in the form of hydraulic or electrical energy to supply the hydraulic energy dissipation device or the electrical equipment of the vehicle, it is possible to reduce the energy consumption of the vehicle. The research of regenerative suspension not only can reduce the energy consumption of the vehicle, but also be substantively meaningful to the exploration of active suspension or semi-active suspension.

Structure scheme of existing regenerative suspension

Rack-and-pinion suspension. The motor and rack pinion mechanism is used to replace the traditional hydraulic shock absorbers in rack and pinion suspension [2,3], and the rack connects the unsprung mass, gear connects the sprung mass, and motor rotor is connected to the gear. When the wheels jump up and down, the gear and rack move relatively to drive the motor rotation, converting the vibration energy of the frame and body into electrical energy through the generator. The structural principle of rack and pinion suspension is shown in figure 1.

The gap between the stator and the rotor is not affected by changes in suspension travel, and electromagnetic induction force is proportional to the speed of the motor, and the adjusting range of damping force is extensive. Weihua Wang, Changmiao Yu and others of Jilin University's proposed a electromagnetic energy regenerative suspension actuator solutions [4] combined the rack and pinion mechanism with DC servo motor .

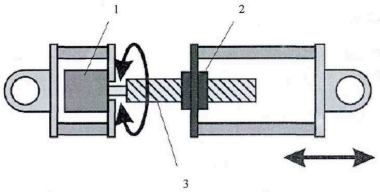
Fig. 1 Structure principle of a rack and pinion suspension

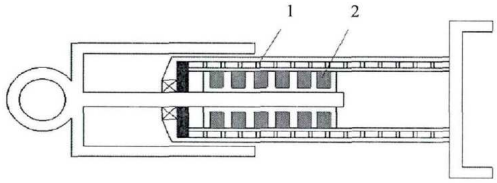
Ball-screw suspension. The ball-screw mechanism is used to replace the traditional hydraulic shock absorbers in ball screw suspension [5,6], and the linear motion of the sprung and unsprung mass is transformed into rotary motion of the motor. The motor and ball screw mechanism consist of feeding components, recovering the vibration energy between the body and wheels into electrical energy. The structural principle of ball suspension is shown in figure 2.

Ball screw suspension alternately compressed and expanded in stroke in the moving process of vehicle, namely the ball nut moves up and down along the axial direction driving the ball screw and motor rotor to rotate. Fan Yu, Xuechun Zheng and others of Shanghai Jiao Tong University designed a suspension combined the ball-screw mechanism with a permanent magnet brushless DC motor according to the domestic and foreign patents[7].



1-Electric motor, 2-Ball nut, 3-Screw

Fig. 2 Structure principle of ball screw suspension



1-Magnet, 2-Coil

Fig. 3 Structure principle of linear motor suspension

Linear motor suspension. A linear motor is used to replace the traditional hydraulic shock absorber in linear motor suspension [8], and the mechanical energy of the linear motion between the body and the frame is converted directly to electric energy, or in turn. The motor is in the electric or braking state according to control instruction, so as to initiatively ease and attenuate the impact caused by the uneven pavement. The structural principle of linear motor suspension is shown in Figure 3.

When the motor generates electricity, the counter electromotive force generated by the motor works as the damping force of the suspension system to attenuate vibration. Bose Company adopts the scheme in initial loading test, and the results show that the scheme can realize the vibration energy recovery.

Fluid power regenerative suspension. Fluid power regenerative suspension [9, 10, 11] is to transform the linear motion of the vehicle sprung and unsprung mass into invariable direction rotational motion of hydraulic motor through hydraulic rectifier bridge, driving the generator connected generating electricity, and transforming the vibration energy between the body and the wheel into electrical energy. Use the damping effect of counter electromotive force in generator to simulate the role of traditional hydraulic shock absorber damping. Structural principle of fluid power regenerative suspension is shown in Figure 4.

Xuexun Guo, Lin Xu and others of Wuhan University of Technology proposed an energy recovery scheme, and then had simulation analysis and bench tests have test, and both of which verified the feasibility of energy recovery principles and the effectiveness of the scheme.

Measurement index

The existing structural schemes of feed-suspension are complex and diverse. In order to be able to reasonably evaluate various types of feed-suspension and be easy to carry out further research on the feed-suspension, it is necessary to establish a unified measure.

Basic characteristics of the suspension. The basic characteristic of the feed-suspension is the basic condition to realize the vibrational energy recycling dissipated in the form of heat transformed in traditional hydraulic shock absorber suspension, that's the three indicators in suspension system associated with ride comfort and handling stability - body acceleration, suspension dynamic deflections and wheel dynamic load. The three indicators should be quite the same with that of the traditional hydraulic shock absorber suspension.

The characteristics of feeding energy. The feeding energy characteristics of the feed-suspension are the stored form of energy that recycled from vibrational energy between the body and the wheels, and the feed-energy efficiency. Feed-energy efficiency can reflect the size of the recycling energy, which is the efficiency transformed to electricity from vibration energy in feed-suspension.

Linear motor suspension can transform excitation energy into electric energy directly, which has less energy transfer [8], so high efficiency. Compared with the liner motor suspension, rack and pinion suspension has smaller copper loss and relatively high feed-energy efficiency. Ball screw suspension generally has no mechanical rectifier bridge, and the motor rotor is in a process of continuous reversing, so it has lower energy efficiency. The design and performance of hydraulic rectifier bridge in fluid power regenerative suspension is easier than the mechanical rectifier bridge. The hydraulic rectifier bridge rectifier not only can implement effective rectification, the rectifying effect can also be realized by matching the appropriate check valve in the high-frequency excitation, so this scheme has a more efficient generator [11].

Structural Reliability. Structural reliability of the feed-agency is one of the important aspects considered in the design of energy regenerative suspension, which reflects the organization's work processes and determines the comprehensive performance of the feed-suspension. Meanwhile, the manufacturing cost of the suspension and installability cannot be ignored.

When the pavement impact is too large, it is easy to cause tooth fracture of rack and pinion mechanism in the work process of rack and pinion feed-suspension. And it is easy to cause fatigue failure under the long time use of harsh conditions, so this suspension has lower structural reliability [3]. Ball-type feed-suspension has a strong ability of anti-interference for bad environment, and it has a high structural reliability. It has a longer working life than that of rack and pinion suspension, and small size of installation. The volume of linear motor feed-suspension is small, but the structural reliability is general. Since the liner motor itself is expensive, the manufacturing cost is relatively high. The accumulator can greatly weaken the impact of the shock when the fluid power regenerative suspension suffers significant road shocks and it will be able to gradually release the impact energy after the impact, so the structural reliability of this scheme is much better.

Conclusion

Through the detailed introduction of structure principles of four kinds of main feed-suspension, the measurement index of feed-suspension is summarized. It is not difficult to find that the ball screw suspension and fluid power regenerative suspension are structure schemes with strong research, but due to the complexity of the suspension's structural parameters matching and damping force's adjustment, these schemes have not yet entered the final stage of real vehicle performance testing, and they are still in the stage of theoretical analysis and simulating adjustment. It's the developing direction of feed-suspension to achieve the control of damping force and the improvement of feed-efficiency under the premise of guaranteed basic characteristics of the feed-suspension; it is also the technology breakthrough for the future development of the active suspension/semi-active suspension.

Method Research on Bending Fatigue Test of Vehicle Steering Wheel

Xunjiong Xu [1, a], Liang Tian [2, b]

School of Automotive Engineering, Wuhan University of Technology, Wuhan 430070, China
School of Naval Architecture and Ocean Engineering, Wuhan Technical College of Communications, Wuhan 430065, China

Keywords: Steering-wheel, actuator, counter, pressure sensor, displacement sensor

Abstract. Through researches a new method of bending fatigue test of vehicle steering wheel was raised in this paper. The new method is closer to the actual using condition of vehicle steering wheel, which enhances the reliability of the test.

Bending Fatigue Test of Vehicle Steering Wheel

Steering wheel is a vital part of automobile steering system, which influents the safety of the automobile directly. In order to bearing the steering force from the driver, reliability is very important for a steering wheel. Therefore, the durability test is necessary to checkout if it conforms to the technical requirements or not. With axial force, the steering wheel generates free deformation. The bigger the force, the less the radial distance between the force bearing point and the central plane of the steering wheel. However, the weakest part of the steering wheel was connected rigidly to the actuator with a fastener in the bending fatigue test of vehicle steering wheel at present. Because of the rigid connection between the steering wheel and the actuator, rectilinear motion of actuator adds a lateral force to the deformed steering wheel, which impedes the free deformation of the steering wheel; moreover, in the return stroke of the actuator the speed of the actuator affects the resilience speed of the elastic deformation of the steering wheel, which impedes the elastic recovery of the steering wheel. Therefore, previous method of test can't simulate the actual using condition sufficiently, which influences the accuracy of the test result.

Through researches a durability test bed was proposed in this paper, on which the steering wheel was put on force at both side without any clamp device on the force bearing point of the wheel. Pressure sensor and displacement sensor were used to measure values. On this test bed, the axial loading condition was simulated at the time when the steering wheel sheers off. In this way, the testing condition is closer to the actual using condition.

Description of problem analysis

(1) Unilateral reciprocating actuator is commonly used in present fatigue test bed. In the return stroke, this kind of actuator will impede the free resilience of the steering wheel after the force. In the actual use of steering wheel, man's hand won't impede free resilience of the steering wheel.

(2) Rigid Fasteners bound is used on the force bearing point of the steering wheel present fatigue test bed. Because the connection between the actuator and the steering wheel is rigid, the actuator will apply a outward radial force, which speed up the fatigue fracture of the steering wheel. In the actual use of steering wheel, the force from human hand will change along the displacement orientation, so the radial force won't occur.

(3) At moment, the check method of durability break of the steering wheel is observing crack. There are some disadvantages. Before the crack occurred, the strength of the steering wheel may decline a lot, even disabled. But we can't watch it out. So this method can't meet our requirement.

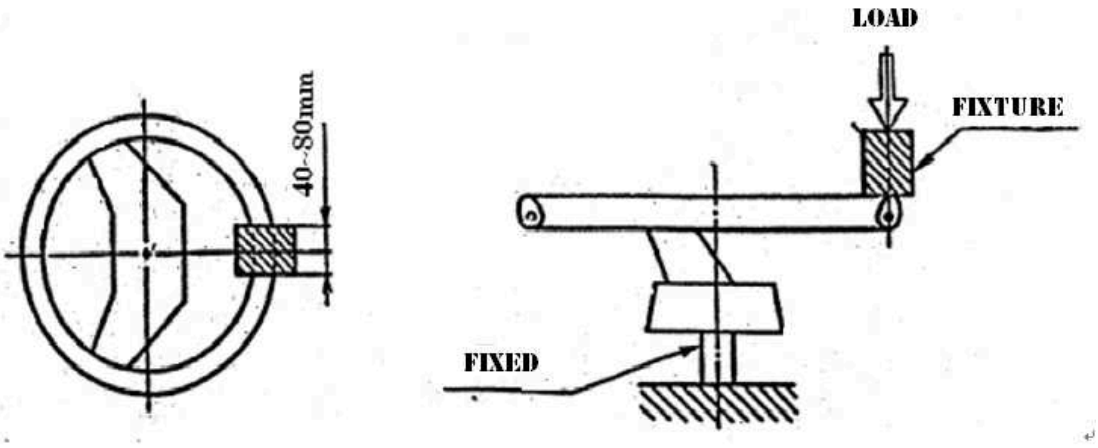

Fig.1 Sketch map of present test bed

Technical proposal of problem solving

(1) On the both sides of the force bearing point of the steering wheel, bidirectional actuator will apply cyclic load on the force bearing point. When the actuator on one side left the steering wheel after finish loading, the actuator on the other side will apply cyclic load.

(2) None constraint construction was used on the actuator, which applied force on the force bearing point. According to the national standard, rigid briquetting was used to guarantee its free deformation.

(3) Form the pressure sensors and the displacement sensors; the force-displacement curve was obtained. So the state of fatigue can be conformed, and the performance of the steering wheel can be tested.

Implementation of the technique proposal

The platform 1 with T slot fixed two square boxes 2 with T slot (fig.2). The distance between the two boxes is adjustable. Two bidirectional actuators were fixed on the boxes respectively. They are in the same horizontal plane. The actuator 3 with 2 guide bars moves up and down along the box 2. Fix the steering wheel on one of the box 2, the steering wheel can move up and down along the box 2 with T slot. In this way, the steering wheel can be fixed on proper position. Two pressure sensors were installed on the cylinder rod of the actuator 3 with guide bar. Two briquetting 7 were put on the pressure sensor 4. On one side of the box, an actuator 5 is fixed, connected with the pressure sensor 4 rigidly.

At the same time, the movement of box 2 with T slot, actuator 3 and the steering wheel 6, makes the briquetting 7 pointing on the both side of weakest part of the steering wheel 6. Then the actuator 3 with guide bar applied load on the weakest part of the steering wheel 6. Adjust the actuating time of the actuator 3 with guide bar, to realize the alternate loading of the two actuators, on the weakest part of the steering wheel 6. Pressure sensor 4 was used to monitor the force applied to the steering wheel 6. According to the data measured by pressure sensor 4 and displacement 8, the force-displacement curve was obtained. To judge the wheel fatigue state through counter 5 can read actuators on the steering wheel 6 times the force applied, counting functions.

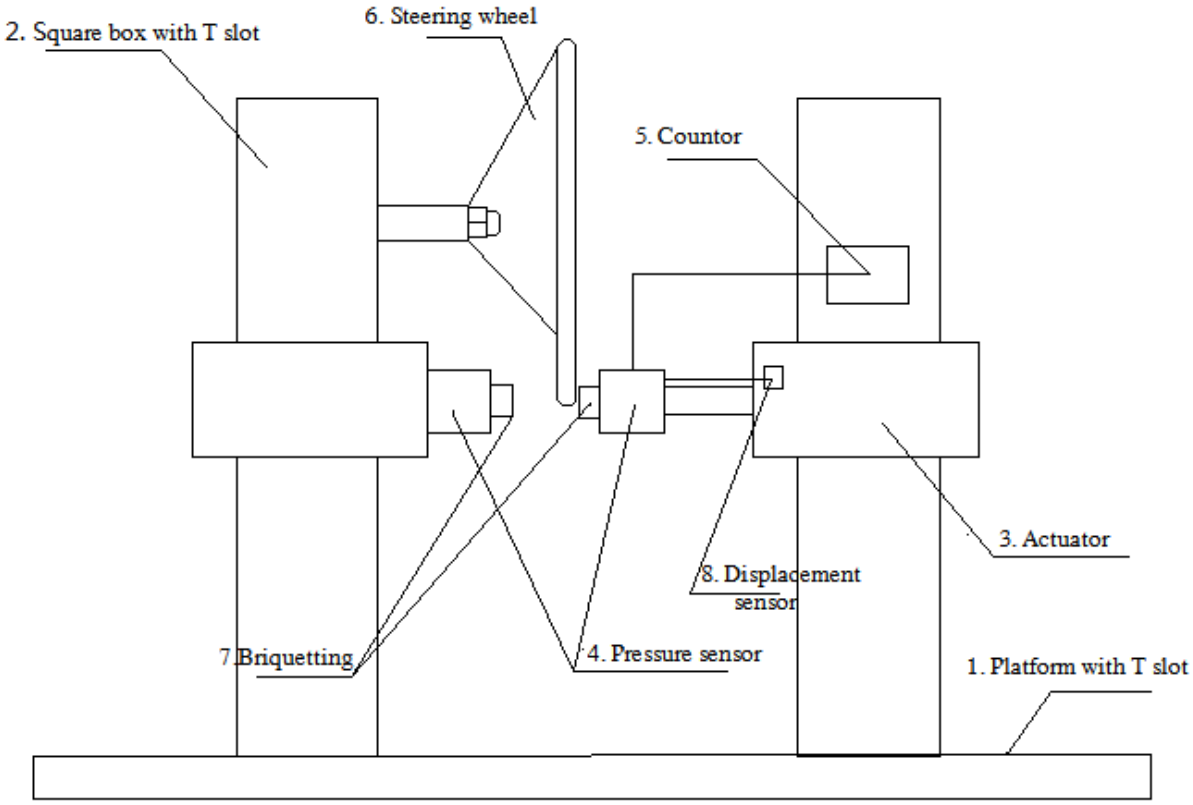

Fig.2 Bed structure of new proposal

Characteristics of the technique proposal

(1) Bidirectional actuators were used to apply load on the both sides of the weakest part of the steering wheel.

(2) The force bearing point of the steering wheel is free of clamp device. According to the national standard, Size of rules of extruded rigid blocks was used.

(3) The use of platform with T slot and boxes is convenient for the movement of steering wheel up and down, and finding the best force bearing point.

(4) Through the data measured by pressure sensors and displacement sensors, it is easy to conform the state of fatigue of steering wheel and to go on performance of the steering wheel.

(5) The counter can read the times that the actuator applied force on the steering wheel.

Conclusion

Through the alternate load that the two actuators applied on the steering wheel, the test process simulated the actual use condition that human hand handling the steering wheel sufficiently, which increased the reliability of the test result greatly. The pressure sensors and the displacement sensors can monitor the force that the actuator applied on the steering wheel in real time. So we can obtain the force-displacement curve, which can show the state of fatigue and the performance of the steering wheel. Force applying times of actuator that recorded by the counter is used for the verification durability of the steering wheel.

The Method of the Abnormal Sound Detection for Final Drive Based on DSP Technology

Xunjiong Xu [a], Zhigang Fang [b, *]

School of Automotive Engineering, Wuhan University of Technology, Wuhan 430070, China

[a] 314117748@qq.com, [b] Zhigang_Fang@whut.edu.cn

Keywords: Abnormal sound detection; DSP; Final drive.

Abstract. According to the mechanism of the main reducer abnormal sound signal is different from the interfering noise, a detection method based on the digital signal processing technology was proposed. With the qualified main reducer noise signal as the reduction sample, the detected main reducer noise signal is de-noising by means of spectrum analysis, and then be estimated whether the detected main reducer is qualified based on certain threshold values. Finally, the detection method is validated, which provided a new thought on the final drive abnormal sound on-line detection.

Introduction

The final drive abnormal sound is generated because of the defects of components or assembly (such as the tooth surface bump, tooth root interference, poor contact area, bearing indentation, etc.), resulting in an abnormal sound when it driving. The abnormal sound not only makes the vehicle not meet the noise standard and regulation and prone to early failure, but also it has some security risks. Therefore, it is necessary to do abnormal sound detection to prevent substandard product flowing out of production line in the main reduction assembly process.

Although the automotive NVH test technology has been greatly developed, but the automated detection technology for the final drive abnormal sound is not universal because of the cost, versatility and reliability of equipment, etc. The existing detection technology is still based on human listening with noise and vibration detection supplemented，which is that the result of human ears is as the primary judgments. Experienced listener is hard to be trained and tend to make wrong judgments when tired and not concentrated after long hour works. Therefore, the research on automated detection method of the final drive abnormal sound has great practical significance.

In the abnormal sound detection processing, with the ambient noise and normal noise interfering when testing equipment and main reducer working and the intensity of abnormal sound usually lower than the interference noise, it's unable to judge directly whether the final drive abnormal sound exists by the noise signal intensity. Because the mechanism of the main reducer abnormal sound signal is different from the interfering noise, its spectrum information and interfering noise have great difference. For the abnormal sound, a detection method based on the digital signal processing technology was proposed, which is simple, practical and benefit for the automatic online detection of abnormal sound for final drive.

Digital Signal Processing Introduction

Digital Signal Processing (DSP) is a technical discipline on signal analysis, conversion, filtering, detection, modulation, demodulation and fast algorithm by digital method. This method captures target signal by dealing with original signal to make signals easy to be captured and utilized. Since its birth in the 1960s, with the development of digital circuits, system technology and computer technology, the theory and technology of DSP is becoming more and more sophisticated. DSP has been gradually replaced by analog signal processing, which has been widely used in various fields like multimedia communications, wireless applications, robot control, audio signal processing, biomedical science and physical geography, etc [1]. Signal spectrum analysis is an important tool for

digital signal processing technology. It's easy to get an in-depth understanding of the characteristics of the signal by analyzing and processing signals from frequency domain. Traditional spectrum analyzers are expensive, bulky and not convenient to be carried by engineering technicians. But with the development of computer technology, the virtual spectrum analyzers have changed the overall design concept of original spectrum analyzer by using software instead of hardware and made the engineering and technical personnel can easily complete the acquisition, processing and frequency signal spectrum analysis just with a laptop computer carried to the site [2].

Method of the Abnormal Sound Detection for Final Drive Based on DSP Technology

In the main reducer abnormal sound detection, with the ambient noise and normal noise interfering when the main reducer working, if the traditional control technology of noise is applied to reduce noise, through isolating the noise source, using muffler and different sound absorbing materials and improving system structure to reduce resonance mode, it is much pricy and hard to achieve the desired results. The main reducer noise detection method based on the concept of active noise reduction, use the incoherence characteristic of noise spectrum of different system to do spectrum analysis to identify and suppress the noise signal, which can achieve the elimination of noise interference and keep the abnormal sound signal [3-4].

Detection Thinking. Due to the different part production batches and abnormal sound modes, the final drive abnormal sound regularity is too complicated to do statistical calculation, while the thinking of this detection is based on the high volume of qualified noise samples(normal signals) formed after collection, analysis, counting and authentication through human judgment and then removing the "normal signal" section of the spectral analysis of noise signal to be detected and the rest deviates from the "normal signals ".So without statistical regularity, it can identify the abnormal noise reducer only through setting the threshold the "normal signals" allowed to be deviated from.

Firstly, with the qualified representative sample by human judgment being a standard and the operating noise being a sample, the signals of the ambient noise, equipment idling noise and the operating noise in the actual detection process are simultaneously recorded. Then noise reduction is performed on the operating noise signal by spectral analysis. At last, the threshold judgment is performed on the post-processing waveform to be tested whether the final drive is qualified. For the compatibility and identification of different types of final drives, library of sample noises of various final drives should be built by sample noise signals of standard final drives of various types and car models.

Detection Processing. Fast Fourier Transformation (FFT) algorithm, which is commonly used nowadays ， is utilized to reduce noise in the detection process, and the process can be divided into three steps [5-6]:

(1)Perform FFT on the sampled signals;

(2)Suppress the spectrum of target signal noise;

(3)Perform Fourier reverse transform on the processed signals;

Presume that collected signal is $f(t)$, the signal after noise reduction is $g(t)$, its Fourier Transformation result is $F(\omega)$ and $G(\omega)$, signal used by filter to suppress noise is $H(\omega)$ and the whole process can be showed as below:

$$G(\omega) = H(\omega) \cdot F(\omega)$$

The whole online detection process of abnormal sound for final drive is showed in Fig.1.

Effectiveness Verification. Each 10 of the qualified，tooth surface roughness，tooth scraping sound and tooth surface bump is picked by human ears, this detection method is used to detect and recognize abnormal sound. All the 40 main reducers can be identified correctly once after the empirical parameters are set.

The figures below from 2 to 5 indicate the contrasts of the waves before and after the process of noise reduction of one of the four final drives. The abscissa of each figure is time(s) and the ordinate is norm.

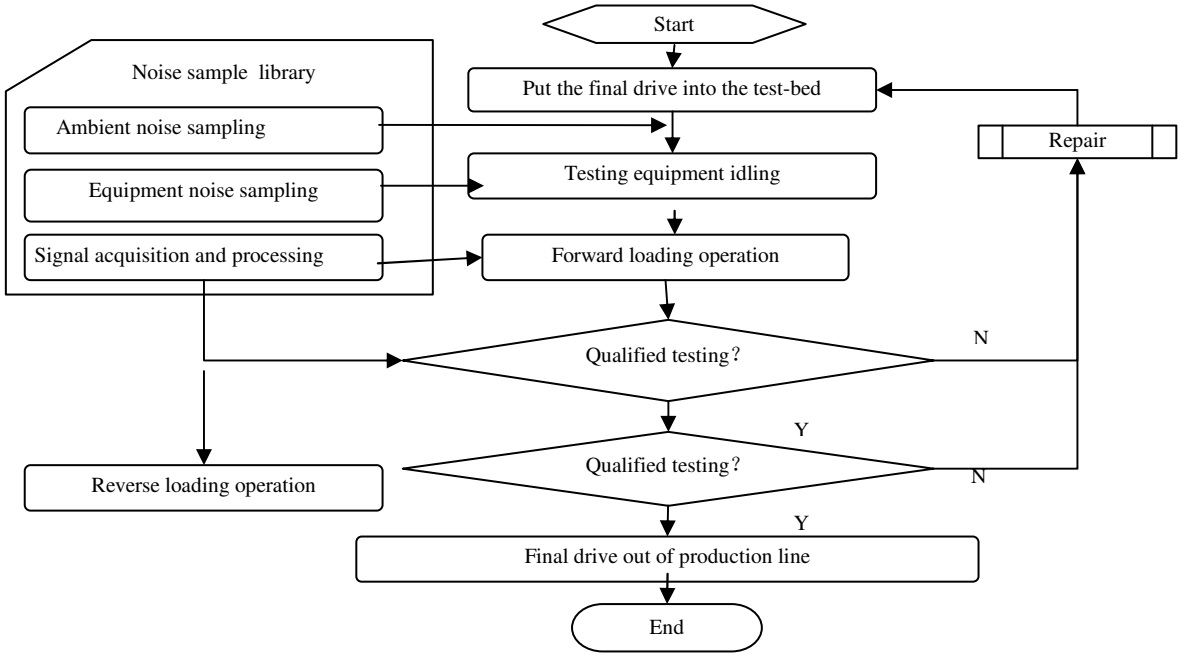

Fig.1 Detection processing of abnormal sound for final drive

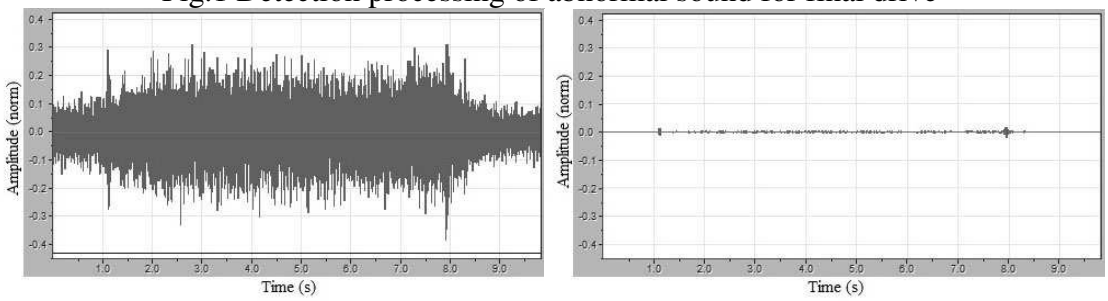
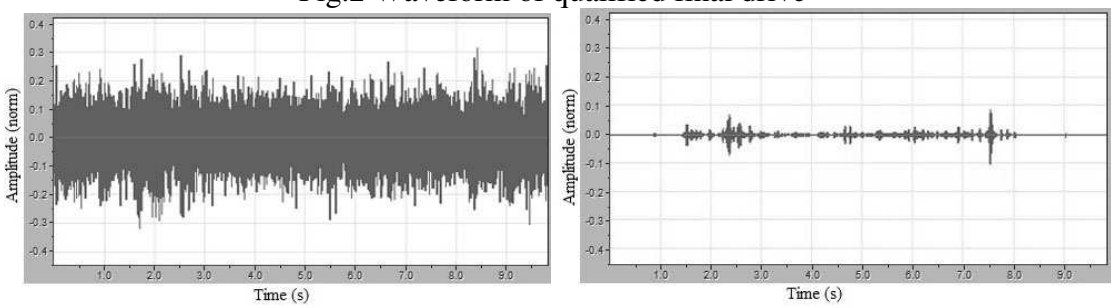


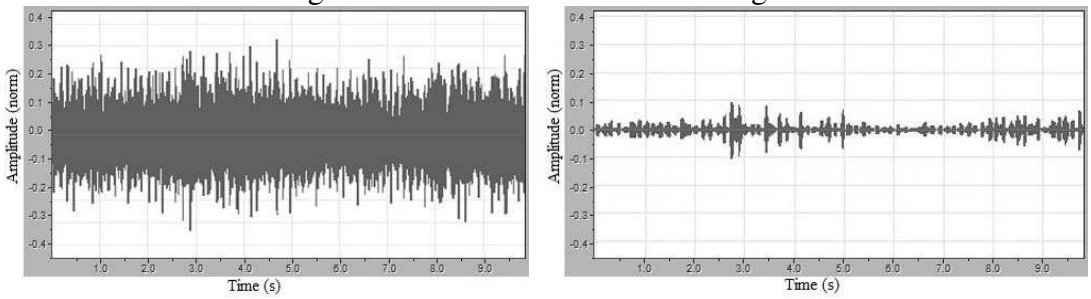
(a) before noise reduction processing (b) after noise reduction processin

Fig.2 Waveform of qualified final drive



(a) before noise reduction processing (b) after noise reduction processin

Fig.3 Waveform of tooth surface roughness final drive



(a) before noise reduction processing (b) after noise reduction processin

Fig.4 Waveform of tooth scraping sound final drive

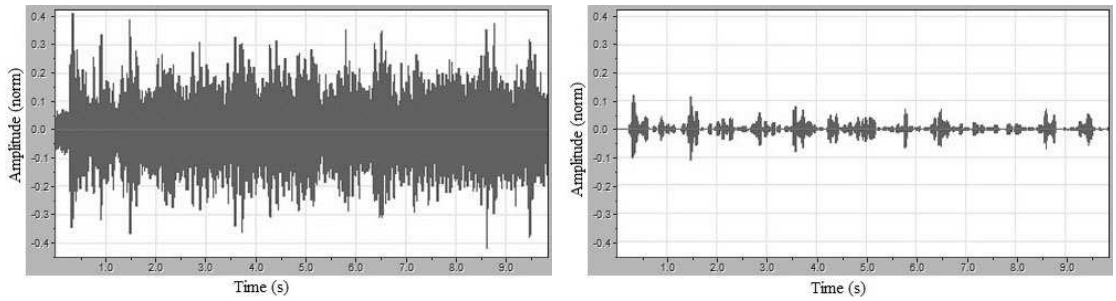
(1). Samples of qualified final drive: it is indicated in Fig.2 (b) that the final drive waveform with the noise interference excluded has only a small amount of residual abnormal sound signals and its

intensity is below a pre-set empirical threshold, so such final drives can be identified as qualified products.

(2). Samples of tooth surface roughness: because the gear tooth surface roughness is unqualified after gears pairing and grinding, it results in abnormal noise when the gear meshing. The waveform of these final drive noise signals after noise reduction processing is shown in Fig.3 (b). Such substandard parts are usually repaired by the way that the gears are re-ground.

(3). Samples of tooth scraping sound: they are usually generated due to the great processing errors or the unreasonable choice of the installation gaskets, resulting in the abnormal noise because of the gear teeth top or root interference when the gears meshing. The waveform of these final drive noise signals after noise reduction processing has obvious abnormal sound，shown in Fig.4 (b). The abnormal sound of such substandard parts is usually eliminated by the way that these installation gaskets are adjusted or the sides of the gears are swept.

(4). Samples of tooth surface bumping: they are usually generated due to the projections or recesses left since the tooth surface contact area bumps into small hard objects when the gears meshing, resulting in the abnormal noise when the gears meshing and the abnormal sound period is significantly inversely proportional to the input speed of the final drive. The waveform of these final drive noise signals after noise reduction processing is shown in Fig. 5 (b). The abnormal sound of such substandard parts is usually eliminated by the way that these bumping points are grinding and removed.



(a) before noise reduction processing (b) after noise reduction processing

Fig.5 Waveform of tooth surface bumping final drive

Conclusion

According to the effectiveness verification above, the method of the abnormal sound detection for final drive based on DSP technology meets the requirements of online detection. Compared with other detection methods, the method is simple and convenient, easy to be implemented and applicable for detecting specific target signals under the other needs.

Keywords: Transmission gear, multi-body contact dynamics, gear meshing force

Abstract. Based on the theory of gear dynamics and contact, the paper uses multi-rigid-body dynamics software ADAMS to build transmission simulation model. The model takes the highest shift gears of a transmission as objects to finish gear meshing simulation analysis. The corresponding meshing force and its Fourier transform results are acquired based on the analysis to get the transmission gears meshing properties.

Introduction

Transmission is mainly used to change the torque and rotational speed from the engine to the drive wheels. Mechanical transmission of power transmission is accomplished through a gear system. In the process of meshing gear, single and double gear engaging period alternate with shocks when engaging-in and out. The shock will cause load change and rotation speed fluctuation, and then vibration problems. As the main part of load bearing and power transferring, the gear transmission may come up with multiple problems such as fatigue, fracture，abrasion, noise vibration, etc. Therefore, it is necessary to analyze the characteristics of the gear meshing process, provide the basis for design and assessment of the gear system. In view of the gear system dynamics simulation, many scholars and experts have carried on thorough analysis with some achievements [1-7]. Their researches are mainly concentrated in the meshing gear pair alone or empirical formula. The idea of taking the whole gear system as the object for analysis will be a good direction. But the using the numerical methods such as finite element method requires the precision calculation of the simulation model and the high equipment of computer hardware. So it is necessary to adopt a more rapid and efficient method to obtain more credible data. Based on a variety of algorithms and the evaluation of software, in this paper the ADAMS software is chosen for the analysis of the gear transmission system, contact algorithm is adopted to build multi-body dynamics model, and then the related results are obtained.

Establishment of the transmission gear system

Mathematical model. In the transmission process of gear system, the shaft and gear can be assumed to be rigid if our main concern is the effect of gear contact. But in the process of gear contact, we need to consider the tooth surface contact because it is a nonlinear contact condition.

In the ADAMS model, we adopt contact collision algorithm, the calculation formula of collision force is

$$F=\begin{cases}\max\left(0,k(x_1-x)^e-STEP(x,x_1-d,C_{\max},x_1,0)\times\dot{x}\right) & x<x_1\\ 0 & x\geq x_1\end{cases} \quad (1)$$

There, x is the distance variable in the collision function. $\dot{x}$ is collision speed, and x_1 represents the displacement.In the model, the contact stiffness of the gear can be simplified according to Hertz contact theory.The calculating formula for the contact stiffness is

$$K=\frac{4}{3}ER^{\frac{1}{2}} \quad (2)$$

There, $R=\frac{R_1R_2}{R_1+R_2}$ represents the synthetical radius of curvature at the meshing point in the tooth profile surface. $E=\frac{E_1+E_2}{(E_1+E_2)(1-\mu^2)}$ is the synthetical elastic modulus. μ is poisson ratio.

The dynamics equationof gear system considering contact can be expressed as

$$\begin{cases} M\ddot{q}+Kq+f_q^T\lambda=Q+F \\ f(q,t)=0 \end{cases} \quad (3)$$

There, F is the contact force, Q is generalized matrix. M and K is generalized mass matrix and generalized stiffness matrix respectively. $f(q,t)$ is constraint equation. f_q^T is the jacobian matix of constraint equation. λ is the Lagrangian multiplier.

The numerical calculation was processed under the ADAMS software. In order to simplify the calculation, we proposed several hypotheses below in mathematical modeling:

A. The geometry models only consider the gear pairs and shafts, ignoring the gearbox and other components.
B. Regarding gear pairs and shafts as ideal rigid body, the gear and shaft connection relationships adopt solid or empty set according to the calculated working condition.
C. Simplifying transfer power gear pairs with contact relationship.

Determination of physical property parameter. The physical property parameter was determined by a chosen transmission used in a car. The materials of gears and shaft are $20CrMnTi$ .The Density is $7800kg/m^3$ .The elastic modulus is $2.06+E11N/m^2$ .The Poisson's ratio is 0.3.The parameters of gear pairs are in the table.1 below. The 4th gear pairs are

Table.1 The parameters of gear pairs

	1st	2nd	3rd	4th	5th
Driving gear teeth	14	22	32	22	41
Driven gear teeth	44	39	37	27	27
Transmission ratio				1.227	0.658
modulus	1.95	1.75	1.5	2.25	1.5

Simulation model. Choosing the 5th forward constant speed as the working condition, both the 5th gear pairs and the 4th gear pairs are engaging to transfer motion and force. The input speed was applied on the input shaft with $3000r/\min$, the resistant torque was applied on the output shaft with $88N\bullet m$ .In order to avoid sudden changes of speed and load, the step function was used to make the load process smooth within0.002s. According to the parameters in Table.1， we can calculate the speeds of intermediate shaft and output shaft as follows

$$n_{lay}=n_{in}i_5=3000\times1.227=4556r/\min \quad (4)$$

$$n_{out}=n_{in}i_5i_4=3000\times1.227\times0.658=3711r/\min \quad (5)$$

Based on the mathematical model and hypotheses above, the simulation model is established, as is shown in Fig.1.The speeds of each shaft are shown in Fig.2.the whole simulation time is 0.06s, and the steps are 1000.At 0~0.002s,the speed of input shaft increased from 0 to $3000r/\min$. After that the gear transmission reaches the constant speed period. In the constant speed process, the speed of output shaft and the layshaft fluctuated up and down in their respective theoretical average value.

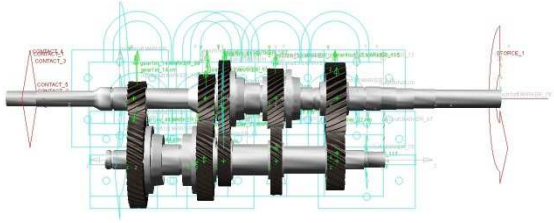

Fig.1 The gear transmission system

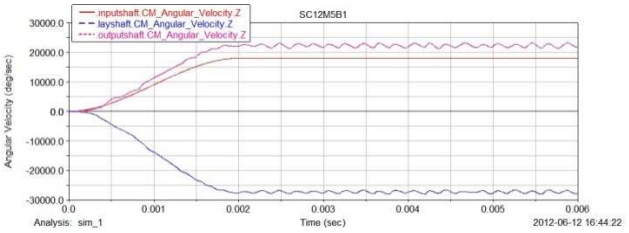

Fig.2 The shaft speed

Simulation results

Gear tooth meshing force. Since the gear models are the ideal models, periodic fluctuations are mainly caused by stiffness excitation and impact excitation. Based on mechanical theory, the involute helical gear circumferential force, radial force and axial force can be calculated as follows:

$$F_t = 2T / d$$
$$F_r = F_t \tan\alpha / \cos\beta \quad (6)$$
$$F_a = T \tan\beta$$

There, T is the torque. d is the reference radius. α is the pressure angle of reference circle. β is the helix angle.

At 5th speed, power flow is transferred by 5th gears and constant meshing gears. The contact forces of the 5th gear pair in the collision process are shown in Fig 3.Before 0.002s, meshing gears rotate from static state to engaging state, undergoing tremendous impact force from each other. So there are large fluctuations in the gear meshing force curves. After 0.002 s, gears turned to uniform motion of the stationary phase. The gear meshing force changes periodic fluctuation near the theoretic average value. Three directions of meshing force extracting from the smooth process and the corresponding theoretical results are shown in Table 2.

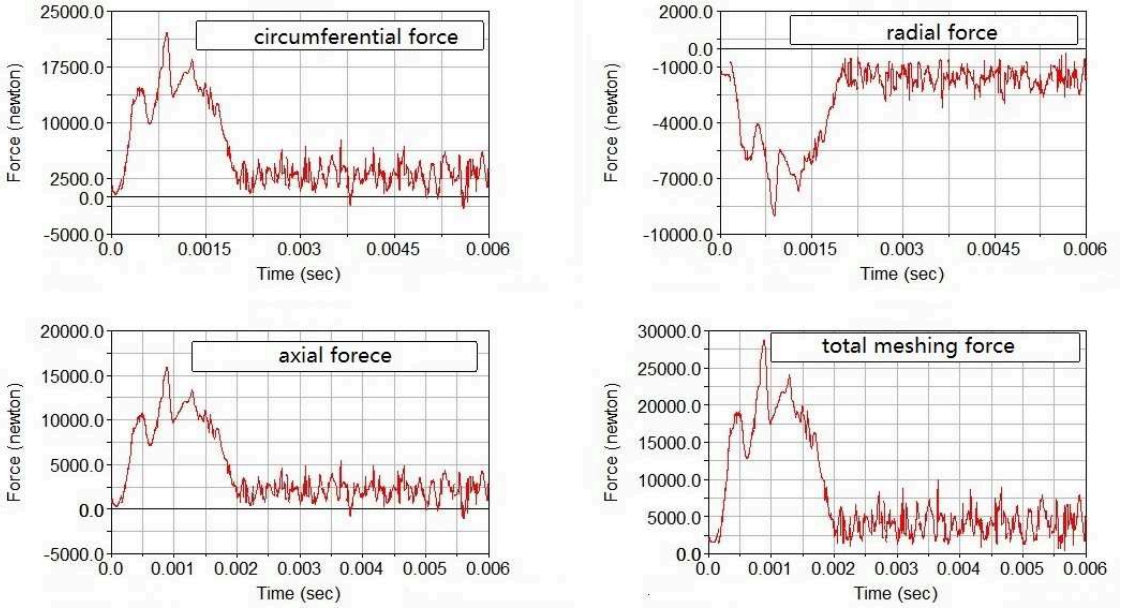

Fig3 The meshing force at 5th gear pairs speed

Table.2 The comparison between the theoretical and simulation meshing forces

Meshing forces (N)	circumferential force	radial force	axial force	total meshing force
Theoretical values	2885	1117	2058	3715
Simulation values	2924	1563	2107	3928

The Fourier transform of meshing force. In order to get periodic data, the simulation time increased to 0.5 s, The corresponding total meshing force is shown in Fig. 4.The Fourier transform of meshing force data is shown in Fig.5.

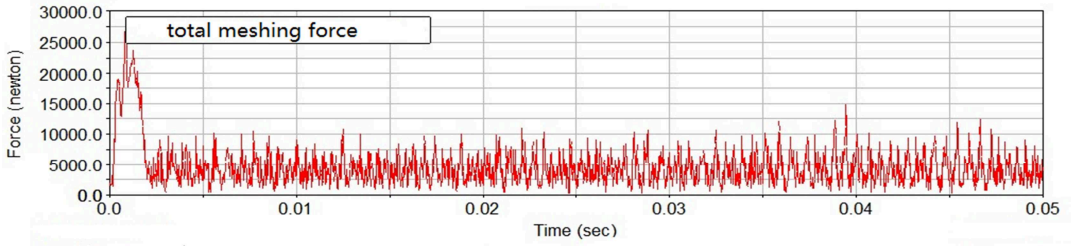

Fig.4 The total meshing force

The theoretical mesh frequency is

$$f = zn / 60 \quad (7)$$

There，z is the number of gear tooth, n is the rotation speed of gear tooth.The comparision of mesh frequency between the theoretical value and simulation value are show in Table.3. The simulation results is consistent from the datas.

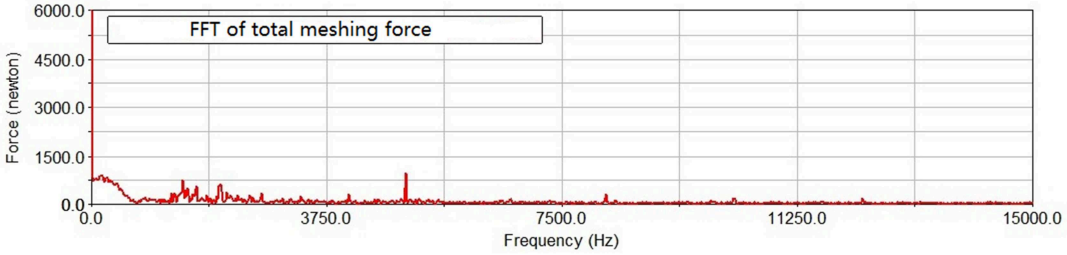

Fig.5 The Fourier transform of total meshing forces

Table.3 The mesh frequency of each shift

Mesh frequency (Hz)	1st	2nd	3rd	4th	5th
Theoretical value	700	1100	1600	1670.4	2050
Simulation value	696	1099	1673	1673.6	2051

Conclusion

This paper built the multi-body dynamics contact simulation model of the transmission gear system. Simulation results can reflect the changes of the system in the gear meshing process. The meshing frequency by using Fourier transform of gear meshing force was agree with the theoretical value Since the computation time is short, the results are reliable, this method can provide a new way of thinking to establish the gear dynamic model. It will help to do the in-deep research on influence of the parameters of the gear dynamic motivation.

Analog Circuit Parameters Measurement System Based on Multiplier

Yongxi Wang [1, a],Mei Hu [1, b]

[1]School of Electronic and Information Engineering, Lanzhou Institute of Technology, Lanzhou 730050,China.

[a]wyx831@126.com, [b]humei-2006@163.com

Keywords: analog circuit parameters, multiplier, measurement system, high accuracy.

Abstract. For the more complicated principles and the lower accuracy for the existing methods of the measurement of the analog circuit parameters, the paper constructs a measurement system for the analog circuits parameters based on the multiplier. The signal source generates two orthogonal sinusoidal analog signals with same frequency, and then one of the signals goes through the analog circuits. Then the multiplication and filtering are completed with the two DC signals. At last the phase and amplitude of the analog circuit are obtained through the DAQ and LabVIEW software. The amplitude and phase errors are less than 3%. The results show that the system has simple circuit, fast speed and high accuracy. So it is a feasible plan for the measurement system of the analog circuit parameters at present.

1. Introduction

Practical application of analog circuits has been a research focus, but its amplitude and phase parameters of the measuring methods are often neglected [1]. The existing measuring methods of analog circuits parameters mainly use simulation software (such as Pspice, Multism), measurement instrument(frequency sweep meter, distortion analyzer, spectrum analyzer, etc.[2]) and some indirect measuring methods such as based on the phase - time transformation, FFT spectrum analysis, correlation function of phase [3]-[7]. Due to the complexity of these principles, the lower accuracy and the methods can't measure the amplitude and phase of the analog circuits at the same time, so these methods are not widely applied. The paper constructs a measurement system for the analog circuits parameters based on the multiplier. The system consists of signal source, the tested analog circuits, the signal processing circuits, ADC and the processing circuits of the DC signals with the LabVIEW software.

The hardware of the system is given in detail. The results show that the system has many advantages of simple circuit, fast speed and high accuracy.

2. Principle of Measurement

There are two orthogonal sinusoidal signals($A_1 \sin \omega t$, $A_1 \cos \omega t$) with same frequency. The $A_1 \sin \omega t$ signal becomes $A_2 \sin(\omega t + \varphi_1)$ after the tested analog circuits are gone by. And then the signal $A_2 \sin(\omega t + \varphi_1)$ multiplies by $A_1 \sin \omega t$ and $A_1 \cos \omega t$ respectively. The second and the more than second harmonic signals ($\frac{A_1 A_2}{2} \cos(2\omega t + \varphi_1)$, $\frac{A_1 A_2}{2} \sin(2\omega t + \varphi_1)$) of the product are filtered by the low-pass filter. Only the rest of the DC signal is $\frac{A_1 A_2}{2} \cos \varphi_1$ and $\frac{A_1 A_2}{2} \sin \varphi_1$. At last the phase φ_1 and amplitude A_2 of the tested analog circuits can be get by mathematical calculations, as shown in formulas 1 ~ 6.

$$A_1 \cos \omega t \times A_2 \sin(\omega t + \varphi_1) = \frac{A_1 A_2}{2} \left[\sin(2\omega t + \varphi_1) + \sin \varphi_1 \right] \tag{1}$$

$$A_1 \sin \omega t \times A_2 \sin(\omega t + \varphi_1) = \frac{A_1 A_2}{2} \left[\cos(2\omega t + \varphi_1) - \cos \varphi_1 \right] \tag{2}$$

$$\frac{A_1 A_2}{2}\cos\varphi_1 = m \tag{3}$$

$$\frac{A_1 A_2}{2}\sin\varphi_1 = n \tag{4}$$

$$\begin{cases} \varphi_1 = arctg\dfrac{nA_1}{mA_2} & (5) \\ A_2 = \dfrac{2\sqrt{m^2+n^2}}{A_1} & (6) \end{cases}$$

3. Measurement System

3.1 System Block Diagram

On the basis of the above principles the measurement system for the analog circuits parameters based on the multiplier is build. The system is composed of the signal source, the tested analog circuits, the multiplication circuit, the filters, ADC and the processing circuits of the DC signals with the LabVIEW software. The phase shift circuit as a signal source to produce two orthogonal sinusoidal signals with the same frequency. After one of the above signals goes through the tested analog circuit multiplies by the two orthogonal signals respectively, then the signals are filtered. The two dc signals are dealt with the DAQ data acquisition card and the LabVIEW software by collecting and calculating signals to get phase and amplitude of analog circuit. The principle block diagram of the measurement system is shown in fig.1.

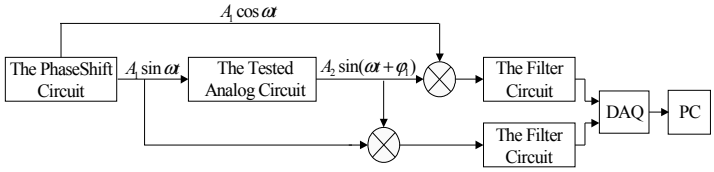

Fig.1 Analog circuit parameters measurement system principle block diagram

3.2 Signal Source

The active phase shift circuit as a signal source produces two orthogonal sinusoidal signals with the same frequency, as shown in fig.2. The input and output signal become the orthogonal signals by means of choosing potentiometer resistance in simulation experiments.

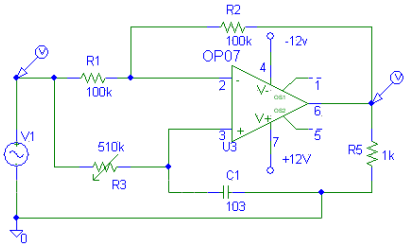

Fig.2 Active phase shift circuit

3.3 Signal Processing Circuit

The signal source generates two sinusoidal orthogonal signals with same frequency, which multiply by $A_2\sin(\omega t+\varphi_1)$. The MLT04 chip integrating four independent multipliers in Analog Devices Inc is used in the multiplication circuit. Its input and output are voltage. Calculation formula of the output voltage is as follows $W = X\times Y/2.5V$ [8].

The products go through the filter to generate two dc signals by filtering the second and the more than second harmonic signals. The resistance of 500kΩ and 100kΩ are connected respectively with two 500kΩ potentiometer in parallel to emerges the low-pass filter with different cutoff frequency, which filters the harmonic signals in different frequencies. The output of the filter is connected to the voltage follower in order to improve the input impedance and the stability of the output signal.

3.4 ADC

The ADC module uses the NI PCI-6024E, which is driven by NI-DAQ software, supporting the LabVIEW and many application development environment. The NI PCI-6024E contains 12 bit A/D converter with the highest sampling rate of 200 kbit/s [9].

3.5 DC Signals Processing with LabVIEW

The dc signal is dealt with by the LabVIEW software, which is collected by PCI – 6024E. The sampling points, acquisition channels, sample rate, the amplitude of sine and cosine are set in the software. The LabVIEW software uses the Function template→the subtemplate of All Functions→the subtemplate of NI Measurement→ the subtemplate of Data Acquisition→AI Acquire Waveform.vi's node in the subtemplate of Analog Input. Finally the phase and amplitude are got on the front panel as shown in fig.3.

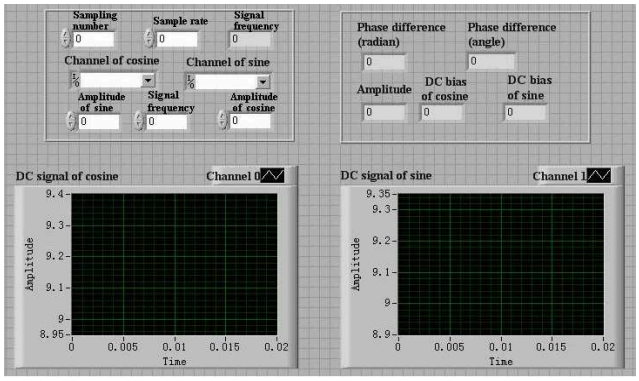

Fig.3 The front panel

4. Experimental Results and Analysis

The first-order RC low-pass filter is the tested circuit. The amplitude-frequency curve, the phase-frequency and curve error curve are shown in fig. 4 and 5. The error curve of phase-frequency is relatively flat in the entire spectrum and the error is less than 2%. While the error curve of amplitude-frequency has sharp fluctuations but the error is within 3%.

Because two multiplied signals reduce the intermediate process and effectively suppress the interference signals. The dc signal which is collected by the data acquisition card reduces the requirement for the performance of the front-end hardware circuit, avoiding the distortion of sampling. Thus the amplitude and phase errors are less than 3%.

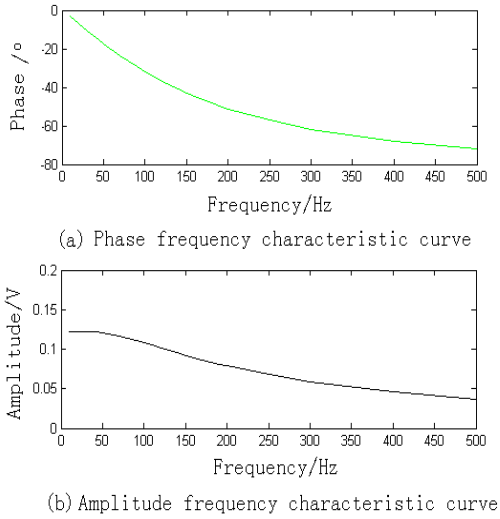

Fig.4 First-order RC low-pass filter phase frequency and amplitude frequency characteristic curve

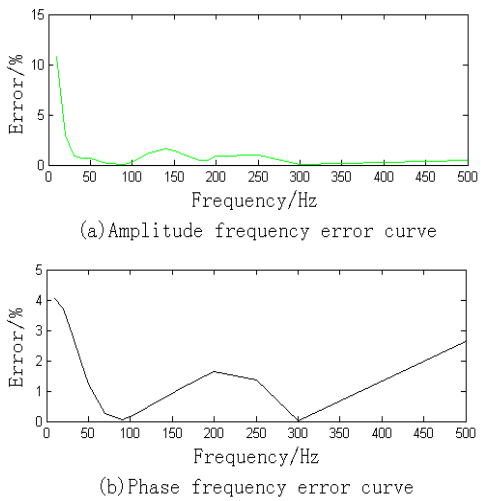

Fig.5 First order RC low-pass filter amplitude frequency and phase frequency error curve

5. Conclusions

On the basis of the above principles the measurement system for the analog circuits parameters based on the multiplier is build. This paper details the system structure, each function module and the experimental results. Results show that the system has some advantages such as simple circuit, easy implementation, the higher accuracy and faster speed. So it is a practical plan for the measurement system of the analog circuit parameters at present.

Keywords: skid steering, dynamic characteristic, co-simulation.

Abstract. In order to analyze the steering dynamic characteristic of the skid steer loader, refer to the theory of tracked vehicle, established the steering Kinematic and dynamic models. use AMESim software platform and Motion software platform to establish a Co-Simulation model of steering system based on theoretical analysis of skid steer loader steering travel. The results show that: the model can predict the dynamic characteristics of the skid steer loader skid steering process.

Introduction

Skid steer loader adopts hydrostatic driving technology and the traveling system adopts double closed-loop systems and the variable pump drive traveling motor which transmit power to the wheel via chains to rotate the tires. Since there is no differential device, when the vehicle is steering, it rely on the speed difference of both sides of the tire. Due to the current published relevant results which research for skid steering load characteristics of skid steer loader are rare and the research results in other fields can be used .Therefore, this paper conduct the research from two aspects. The first one is skid theory of tracked vehicle, the main research results in this area include that Bruce Maclaurin and others who use magic formula to study skid characteristics of tracked vehicles get good results, which proves that the magic formula for rubber tires can also apply to the vehicle skid theory[2,3]. This can help establish the skid steering theory of wheeled skid steer loader. The other one is the load characteristics theory of the tire and the ground .Michael and others who have researched on control method of wheeled skid robot steering process developed a corresponding control system which achieved good control accuracy[1]. Jesus morales and others have researched the energy loss of tracked vehicle skid process[5]. Jingang yi and others have analyzed the kinematics and dynamics characteristics of wheeled skid robot and designed the control system by using kalman filter[4].YangLei and others have simulated and analyzed the armored tracked vehicle steering characteristics by using matlab/simulink and analyzed the influence in the hydraulic system pressure of the vehicle speed change[6]. Bekker and others have analyzed the effect relationship between tire and the ground by using test and analysis methods. Karafiath have analyzed the characteristics of the tire steering and skidding in soft ground[7-9]. This can help establish the kinetic model of the tire and the ground. In addition, there are many related researches for matching the engine and hydraulic system, have accumulated a large number of research results which provides a reference for establishing the hydraulic system model in this paper.

The load characteristic of skid steer loader is very complex, especially the load characteristic of tire and the ground in steering process which directly affect the dynamics and stability of the machine. So it is very important to research the load characteristic of tire and the ground in steering process. Traditional research methods mainly base on simple theoretical calculation or using dynamics software to do simulation analysis. This method does not combine the transmission system analysis

and dynamic analysis of the vehicle and ignores a number of key parameters so that it cannot accurately analyze the real steering characteristics of vehicle and the overall performance. So this paper conducts the co-simulation analysis by using multi-body dynamics software Motion and hydraulic system simulation software AMESim. By this way the analysis of vehicle steering characteristics can be more realistic and it is of great significance on the whole vehicle system matching and performance prediction.

1.Kinematic and dynamic models

The kinematics equation in the process of steering is[9]:

$$R = \frac{B}{2}\frac{(r\omega_r + r\omega_l)}{(r\omega_r - r\omega_l)} = \frac{B(K_s+1)}{2(K_s-1)} \tag{1}$$

$$\Omega_z = \frac{r\omega_r + r\omega_l}{2R} = \frac{r\omega_l(K_s-1)}{B} \tag{2}$$

Where, R is the turning radius, Ω_z is the yaw velocity of the vehicle, ω_r is the angular speed of right wheels, ω_l is the angular speed of left wheels, r is the radius of the wheel, K_s is the angular speed ratio ω_r / ω_l.

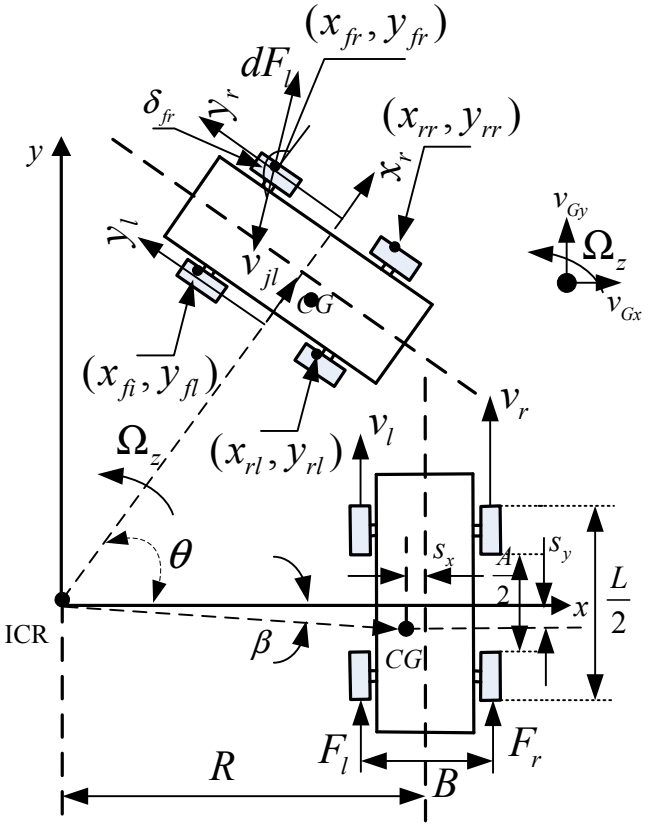

Fig 1 Schematic diagram of the steering of vehicles

When model takes into account the longitudinal slip ratios i_l and i_r of the left and right wheels, the turning radius R' and yaw velocity Ω_z' are given by.

$$R' = \frac{B[K_s(1-i_r)+(1-i_l)]}{2[K_s(1-i_r)-(1-i_l)]} \tag{3}$$

$$\Omega_z' = \frac{r\omega_l[K_s(1-i_r)-(1-i_l)]}{B} \tag{4}$$

Based on theory in [9] assumed the shear stress τ and shear displacement j relationship can be described as follows:

$$\tau = \sigma\mu(1-e^{-j/K}) \tag{5}$$

where σ is the normal pressure, μ is the coefficient of friction between the wheel and the ground, K is the shear deformation modulus, is a terrain-dependent parameter, like the rolling resistance and coefficient of friction, j is the shear displacement.

On the right wheels:

$$dF_r = \tau_r dA = \sigma_r \mu(1-e^{-j_r/K})dA \tag{6}$$

On the left wheels:

$$dF_l = \tau_l dA = \sigma_l \mu(1-e^{-j_r/K})dA \tag{7}$$

Where τ_r and τ_l are the shear stress, σ_r and σ_l are normal pressures, and j_r and j_l are shear displacements of the elements of the right and left wheels, respectively.

The longitudinal forces F_{yr} and F_{yl} can be expressed as follows:

$$F_{yr} = -\int_{A/2}^{L/2}\int_{-b/2}^{b/2}\sigma_r\mu(1-e^{-j_r/K})\sin\delta_{fr}dx_{fr}dy_{fr} - \int_{-A/2}^{-L/2}\int_{-b/2}^{b/2}\sigma_r\mu(1-e^{-j_r/K})\sin\delta_{rr}dx_{rr}dy_{rr} \tag{8}$$

$$F_{yl} = -\int_{A/2}^{L/2}\int_{-b/2}^{b/2}\sigma_{fl}\mu(1-e^{-j_l/K})\sin\delta_{fl}dx_{fl}dy_{fl} - \int_{-A/2}^{-L/2}\int_{-b/2}^{b/2}\sigma_{rl}\mu(1-e^{-j_l/K})\sin\delta_{rl}dx_{rl}dy_{rl} \tag{9}$$

Turning resistance of right wheels and left wheels can be expressed respectively by.

$$M_r = \frac{B}{2}F_{yr} \tag{10}$$

$$M_l = \frac{B}{2}F_{yl} \tag{11}$$

2.Dynamic characteristics simulation analysis of skid steering

In order to establish a more accurate dynamics model of vehicle steering process, this paper use multi-body dynamics software Motion to establish a model of the vehicle and the ground, shown in Figure 2.

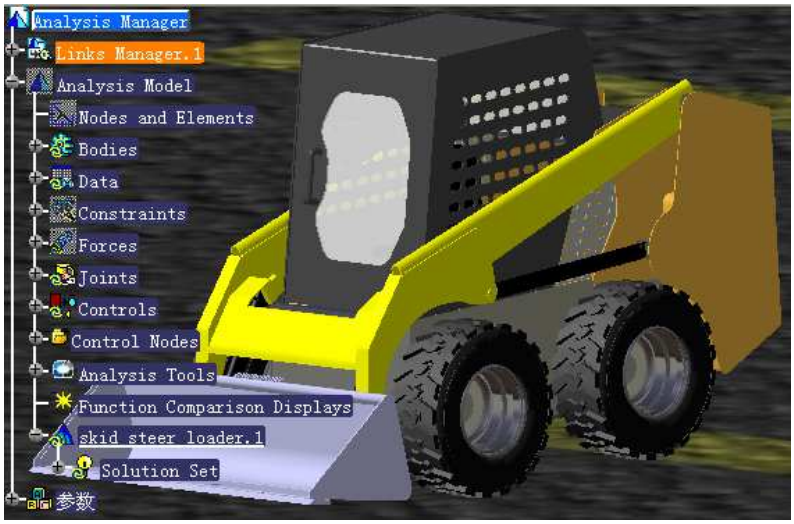

Fig 1 Multi-body dynamics model of vehicle

Take unilateral right steering with rated speed and fully load as an example, left traveling pump is main working pump which drives left traveling motor to output torque for driving the left side tires to overcome friction to move. The right traveling pump is in the neutral position and the right traveling motor is in braking condition, so there is speed difference between left and right side and the vehicle

steers around the slow side. Figure 3 is traveling hydraulic system pressure simulation curve of unilateral right steering, figure 4 is right wheel torque simulation curve of unilateral right steering, and figure 5 is left wheel torque simulation curve of unilateral right steering. Table 1 shows the traveling hydraulic system pressure dynamic response indicators of unilateral steering.

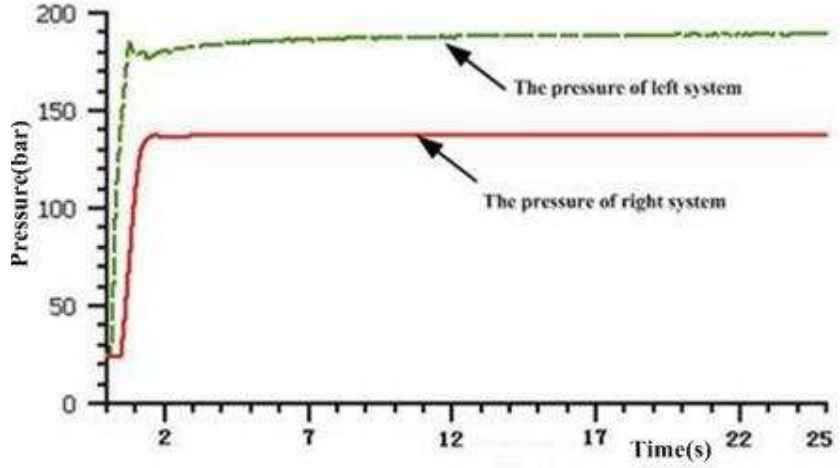

Fig 3 Traveling hydraulic system pressure of unilateral right steering

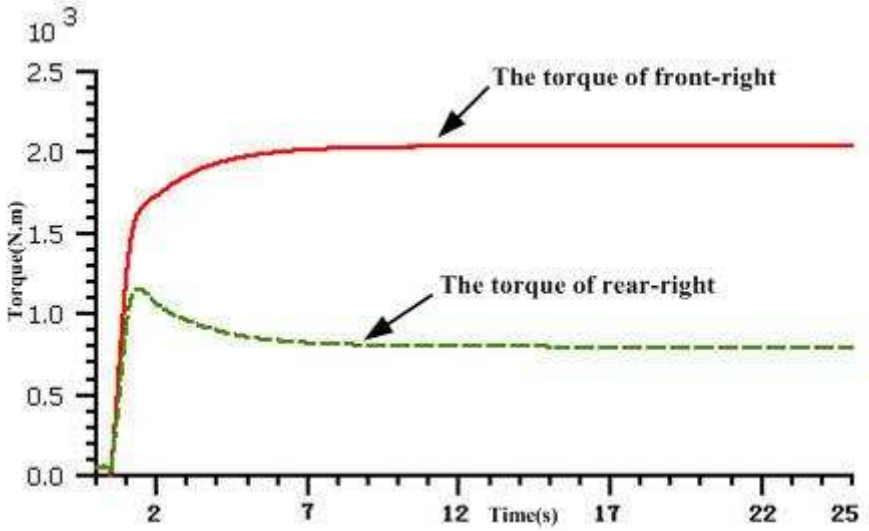

Fig 4 Right wheel torque of unilateral right steering

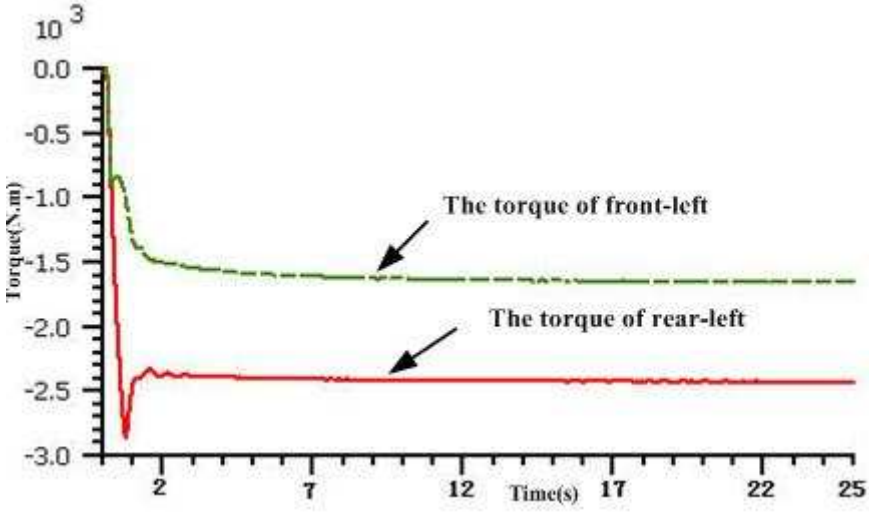

Fig 5 Right wheel torque of unilateral right steering

Table 1 Traveling hydraulic system pressure dynamic response indicators of unilateral steering

unilateral steering	delay s	regulation time s	max pressure MPa	steady pressure MPa	overshoot %
left side pressure	0.64	1.4	18.6	18.2	2.2
right side pressure	0.86	2.1	13.7	13.6	0.7

By figure 3, figure5 and table 1，the motor pressure of high pressure side can reach to 18.6MPa at the beginning of steering. In the unilateral steering stabilization phase, the mean value of left motor pressure is 18.2MPa and the mean value of right motor pressure is 13.6MPa. In this condition, vehicle steering radius is larger than bilateral steering. That means the left motor equivalent moment of inertia is less and so does the system overshoot. Therefore, the pressure of the steering system is relatively stable.

Conclusion

(1) Analyze the steering characteristics of skid-steer loader; establish the kinematics and dynamics model of the vehicle by using the slip theory of tracked vehicle and magic formulas, which provides a theoretical guidance to establish the simulation model.

(2) The test results indicate that, the co-simulation model and test results are relatively close either from the values or trend, which verifies that the method is feasible and the model is accurate. And the model can predict and evaluate the steering performance of the vehicle.

A improvement of the Keep-Right-Except-To-Pass Rule in the model of Modified CA(cellular automata)

Yue Ma

School of North China Electric Power University, Baoding, 07100, China

mayuehuabeidianli@126.com

Keyword: Cellular automata, Variable speed limit , the New Principle.

Abstract. We build the model of Modified CA(cellular automata) to analyze the right-hand drive principle, at the same time we put forward the New Principle(In the principle, right lane is the high-speed lane and vehicles driving on it normally. This paper divides the whole principle process into four stages. The overtaking vehicle(A) send signals to the overtaked one(B),B moves to the low-speed lane to let A pass, A moves straight to finish overtaking and B returns.) and its creation is optimized by the model. At last, we use the model to analyze the traffic conditions in different principles or vehicle density or speed limit.

Introduction

In countries where driving automobiles on the right is the rule, multi-lane freeways often employ a rule that requires drivers to drive in the right-most lane unless they are passing another vehicle, in which case they move one lane to the left, pass, and return to their former travel lane.

There, we face the challenge that we need a mathematical model to analyze the performance of this rule in light and heavy traffic. And we must stress on tradeoffs between traffic flow and safety, the role of under- or over-posted speed limits, and other factors that may not be explicitly called out in this problem statement. We also need to judge whether this rule effective in promoting better traffic flow. If not, we need to create a better one.

Method

·Overtaking parametric analysis:

Two parallel lanes which directions are opposite, one-dimensional chain of discrete points we put each channel is defined as equidistant grid points consisting of "L". The spacing between the grids is 7.5m. Possible states for each grid point are: empty (no cars) or occupied by a vehicle with a speed of V =0,1,2…And the vehicle's maximum speed is $V_{\max}$. Normally the vehicle was traveling along the right lane, only in the process of overtaking can travel on the left direction.

Fig.1 is overtaking situation Schematic, black grids represent vehicles and white grids mean there doesn't have a vehicle. Assume at time "t", when the former vehicle "i" want to transcend the motorcade which length is n before. The spacing between the first vehicle of the motorcade and the closest vehicle in the same direction of it is "u". When overtaking starts, the overtaking sight is "s" ,and the spacing between the former vehicle and the nearest vehicle "j" on the neighbor road is "l".

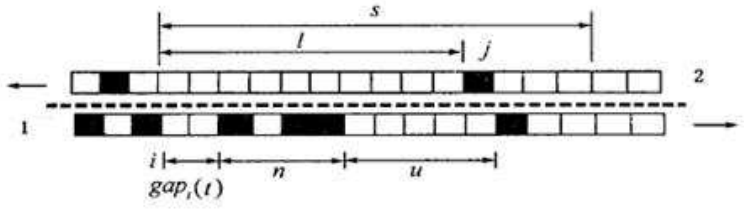

Fig.1 Overtaking analysis schematic diagram

·The analysis of the principle:

·Firstly, we define a new concept"Safety Factor"and we use a"S"to represent it.

$$S = \frac{sd \times \alpha_1}{v \times \alpha_2}$$

Besides, "sd" means the safe distance when overtaking," v" means the maximum limited speed. And"α_1",,"α_2" respectively represent the two factors' weighted calculation.

·The overtaking process contains three stages: lane changing, overtaking and lane returning.

(1) Lane changing condition:

- $v < \overline{V_f}$
- $\int_0^{t_c} (V_{Y_1}^0 + a_{Y_1}^a t) d_t - \int_0^{t_c} (V_{Y_0}^0 + a_{Y_0}^a t) d_t \geq d_s$
- $\int_0^{t_c} (V_{C_1}^0 + a_{C_1}^a t) d_t - \int_0^{t_c} (V_{Y_0}^0 + a_{Y_0}^a t) d_t \geq d_d$

(2)Overtaking condition:

- $v < \overline{V_j}$
- $\int_{t_c}^{t_c+t_0} (V_{C_1}^{t_c} + a_{C_1}^a t) d_t - \int_{t_c}^{t_c+t_0} (V_{Y_0}^{t_c} + a_{Y_0}^a t) d_t \geq d_s$
- $\int_{t_c}^{t_c+t_0} (V_{Y_0}^{t_c} + a_{Y_0}^a t) d_t < \max\{S_{Y_i} + (i+1) + \sum_{i=1}^{n} L_{c_i}\}$

(3)Returning condition:

- $v < \overline{V_j}$
- $\int_{t_{c+t0}}^{t_c+t_0+t_a} (V_{C_1}^{t_c+t_0} + a_{C_1}^a t) d_t - \int_{t_{c+t0}}^{t_c+t_0+t_a} (V_{Y_0}^{t_c+t_0} + a_{Y_0}^a t) d_t \geq d_s$
- $\int_{t_{c+t0}}^{t_c+t_0+t_a} (V_{Y_{(i+1)}}^{t_c+t_0} + a_{Y_{(i+1)}}^a t) d_t - \int_{t_{c+t0}}^{t_c+t_0+t_a} (V_{Y_0}^{t_c+t_0} + a_{Y_0}^a t) d_t \geq d_d$

Above all, under different limited speed conditions, the overtaking model can be described as:

$$\min Z = \max\{0, S_{Y_0} - \max[S_{Y_i} + (i+1) d_s + \sum_{i=1}^{n} L_{c_i}]\}$$

Besides, S_{Y_0} represents the overtaking vehicle's driving distance.

- According to the formulas above, we make out the simulation.

Table 1 Safe distance of following vehicle(A)

Vehicle	Limit at a speed of 60km/h	Limit at a speed of 80km/h	Limit at a speed of 100km/h
Overtaked vehicle	50	60	80
Overtaking vehicle	55	80	95
Following distance	16.73	34.82	50.35

Table 2 Safe distance when the vehicle lane changing(B)

Vehicle	Limit at a speed of 60km/h	Limit at a speed of 80km/h	Limit at a speed of 100km/h
Overtaked vehicle	50	60	80
Overtaking vehicle	55	80	95
Following distance	16.77	24.20	38.96

Table 3 Safe distance when the vehicle overtaking(C)

Vehicle	Limit at a speed of 60km/h	Limit at a speed of 80km/h	Limit at a speed of 100km/h
Overtaked vehicle	50	60	80
Overtaking vehicle	55	80	95
Following distance	13.82	27.80	44.32

To processing this data, we use the expert scoring method and get the weight of each distance. The scale factor of a, b, c is 0.5,0.3,0.2.Then we can get “Safety Factor” in the light or heavy traffic.

Table 4

Limited speed	Safe factor
60	0.457
80	0.375
100	0.267

We can learn from this table that the safe factor moves inversely to the limited speed.

·The right rule, left rule and the new rule’s traffic flow changing diagram is:

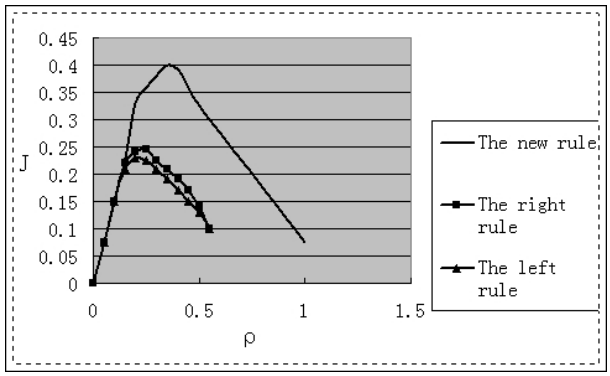

Fig.2 Diagram of different rule

Discussion

We can conclude from the diagram above that the right rule’s impact on the traffic is close to the left rule’s. But when the vehicles obey the new rule, it can improve the traffic flow to a large extent.

In countries where driving automobiles on the left is the norm, the left lane is high-speed lane, when one automobile wants to overtake, whistling and the automobile in front of it(driving in a lower-speed) moves to the right lane. The lower-speed automobile returns to the left lane as soon as the overtaking has been done safely.

Conclusion

In order to analyze traffic performance in different traffic rules, using the software “Matlab”and programming, we creatively establishes a one-way two lane Modified CA traffic flow model. Effect of vehicle density model on traffic flow are studied by numerical simulation. According to the results of our program, we can know that the traffic flow first increases and then decreases as the traffic load’s increasing. At the same condition, the security’s reducing speed increases.

We use the Modified CA model to simulated the New Principle. Learning from the calculation result, we find that our New Principle makes full use of the high-speed lane and the traffic flow increase at a degree of 32%.

Strengths:

·Cleverly use the cellular automata model to simulate the flowing of vehicles.

·Define a new concept“Safety Factor”to analyze the safety issues, quantify the abstract problem and make the calculation clearly.

·The new rule we make can take full advantage of the fast lane to improve the traffic flow on a certain degree.

Design and implementation of remote control system Based on embedded mobile network

Jingxin Wei

NCIST Teaching Affairs Department，Bejing East, Yanjiao 101601

Keywords: SMS, AT instruct.

Abstract: On employing GSM network as the way for data wareless transmission, this thesis puts emphasis on introducing operating principle of TC35i module and AT89C51 as well as the perpheral interface circuit. Meanwhile, it designs the system hardware circuit, computer control solfware and SCM system solfware with offering the application program for TC35i module and AT89C51 interface partially. After the debugging and practising, it comes to the data transmission terminal with GSM module.

1 Introduction

With the development of computer communication technology, computer network monitoring has become an important site monitoring of various technical means necessary for remote monitoring, and using wireless remote monitoring has become the development trend of the control field. GSM network enjoys wide coverage , stable signal, no co-channel interference , confidentiality , massive short messages handling, data and fax transmission and other business functions, and GSM short message is characterized of online without dialing, cheap, wide-range covering, particularly suitable for small flow applications for transmitting data , and is widely used in oil fields , weather, port inspector , water network , hydrology, environmental monitoring, vehicles, ships , mobile operations, and other places.

Simple remote control system consists of two parts-host and remote . Host computer is used to monitor the operation of computers that are connected to a network, while the remote receives the data for the analysis, interpretation and execution. Design and implementation of the design focuses on the host , and a whole host of information to get the design and implementation of the module , the host MCU control via mobile phone module to achieve data transmission system that uses the short message data transmission mode , the system with the use of flexible , reliable operation.

2 Hardware Design

System hardware consists of a computer control center , data transceiver GSM module , single-chip control panels and other parts. Control Center computer using a normal computer, connected to the data transceiver GSM module is the result of conversion chip MAX3238, will be converted into TTL level RS-232 level [1] , and then directly connected to the computer serial port ; For microcomputer control system , GSM data transceiver module connection is through conversion chip MAX232, will be converted into TTL level RS-232 level , and then directly connected to the microcontroller development board serial port.

2.1 GSM data transceiver module

Data transceiver module is mainly composed of TC35i GSM module, SIM cards, interface circuits , antennas and other components , and the core is Siemens TC35i module, with the main function of remote data transmission through the mobile communication network.

Design uses Siemens TC35 Series TC35i. TC35i data interface (CMOS level) is a serial of asynchronous transceiver which meets ITU-TRS232 standard, with 8 data bits and 1 stop bit , no parity. AT command can be bi-directional transfer instructions and data to support Text and PDU format of SMS (Short Message Service, SMS) , available through AT commands or restart and shutdown signal to achieve fault recovery . Because it is relatively simple for Text mode to send and receive the short message, the design is based on AT commands using the Text mode.

2.1.1 Send and delete messages.

Before sending the message , the information must be set to send the transmission format , use the "AT + CMGF = 1" command to send the format to Text mode, the write command "AT + CMGS = other phone numbers " and other GSM module reply " > " symbol can be written to the content to be sent after using the shortcut key " Ctrl + Z " to send text messages , if the messages is issued by the GSM module, it will reply + CMGR: digital , OK; if the error happens, it will reply ERROR.

Filling in the blanks is used to store newly received short message in TC35i, and it will always put the received short message in the smallest ordinal position. When all the stores are filled, it will no longer receive new short message. So after a short message to be processed promptly removed. Delete short message AT command : AT + CMGD = n, where n represents the number of short messages to be deleted.

2.1.2 The short message receiving and storing

Because of the short message's delay in transmission , the short message's arrival time is uncertain . Therefore, you must set the short message arriving prompts command and regular testing [2] , so you can power up when TC35i be initialized achieved. Set short messages arriving automatically prompts the AT command AT + CNMI = 1,1,0,0,1. When you receive a short message arrives + CMTI: "SM", n prompt message, where + CMTI: Prompt header information , "SM ' is short message storage area for the SIM card memory , n is new short message to the specified storage area in the storage number , you can send "AT + CMGR = n" to the specified storage area to read out a short message . After this command is issued, if the GSM module has received a short message, then from the UART interface returns the following information:

+ CMGR: "REC UNREAD", " sender phone number " , "Send Time"

xxxxxxxxxxxxxxxxx (Receive short text message)

2.2 MCU control board

AT89S51 microcontroller control board is mainly composed of microcontroller, digital tube display , eight light-emitting diodes and other components [3] . Its main function is to receive commands and data from the control center , and to control the device (light emitting diode analog). Minimum system design AT89S51 clock signal is generated by the clock signal which is generated by the circuit capacitor C5, C7 and crystal Y1, power-on reset circuit consists of C6, R13 constitute , manual reset circuit consists of S1, R12 composition. In the system C5, C7, we take 22PF, which can stabilize the system clock oscillation stability . In order to ensure a sufficiently wide differential circuit generates a pulse , RC time constant should be more than two machine cycles , here we take 10uF capacitor , 8.2K resistor , AT89S51 minimum system circuit shown in Figure 1.

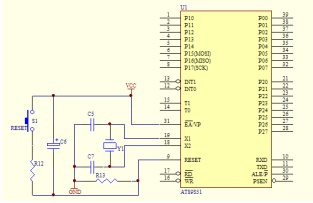

Figure 1 AT89S51 system

3 Software System Design

Mobile communication network remote control system software design includes computer control software, microcontroller control panel software design

3.1 Computer Control Software Design

Computer control interface uses a VB 6.0, and the control interface is very easy to use, and powerful. Control interface shown in Figure 2.

Computer as a control terminal to overcome the microcontroller can not store large amounts of data , no real-time updates of data, and other shortcomings. Computer control terminal is used to initialize the serial device, to send information (communication of information and control

commands) , to receive the information returned by the receiving terminal , to carry out real-time information processing, to store, storage, delete, view information.

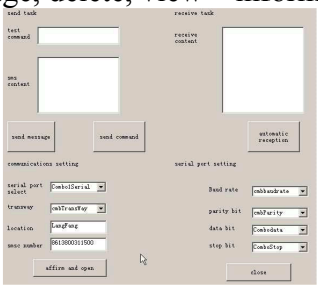

Figure 2 Computer control terminal interface

MSComm control serial events provided by Vb [4] [5] [6]is used for computer communication module TC35i control information processing . Vb program is done through the queries of serial communication control MSComm Oncomm event. After the program starts, it initializes the modem and the serial port.

3.2 SCM system software design

SCM system uses an external microcontroller directly TC35i module to receive information , uses the query method to detect information soon. And receive text messages and read the contents , determine the end of a remote control device , a light emitting diode used here to indicate the state.

4 System debugging

4.1 Computer terminal debugging

After the program 's interface and the code is written , run the application and select End communication configuration after clicking "Confirm configuration and open the serial port " in the back of the test command input after the "AT" clicking "Send Command" , finds that the received content appears "AT OK" behind words , indicating GSM module can communicate with a computer[7] [8] [9] . Now once the process to send and receive text messages , first enter "AT + CMGF = 1" command to set the text in the test format , to receive content appears "AT + CMGF = 1 OK" behind the words ; After the test command input "AT + CMGS = other phone number " to receive content behind a" > "character, the content of the message in the message you want to send the contents of the input click" Send SMS " , if sent successfully , you will receive the content in the event of " + CMGS,, *** OK " words , indicating that the information has been issued , if there is " OK " or " ERROR " word then the information is not given; After the test command input "AT + CNMI = 1,1,0,0,1" Set SMS prompt arrival , when a new message arrives there will be "+ CNMI:" After receiving the contents of the word ME ", <index>", which indicates the position of <index> just received text messages stored , you can read the messages based on this parameter to write programs ; according to the location to get the message , and after the test command input "AT + CMGR = <index>", at the reception content will appear after "+ CMGR:" REC UNREAD "," sender phone number " , " message received time " message content " OK "; To delete a message long after the test command input "AT + CMGD = <index>" can be. Meanwhile module has closed echo function , for close echo enter the word "ATE0" in the test command, appears the word "OK" after receiving the content only after the above test , the function can achieve , computer terminal debugging success.

4.2 SCM side debugging

After you have written SCM test program , you should first burn the program into the microcontroller , double tick Easy 51Pro.exe programmer icon. When the program starts , after automatic hardware detection and connection, in status box will display the word " Ready ", which means that the programmer connections and settings are normal. After repeated testing , the system is working properly.

5 Conclusion

The design, with the use of VB, develops successfully a set of message system to receive and send messages. And receiving and sending text messages via a PC is used to achieve the desired results. In addition , the remote host, the single-chip control panel, sends text messages to the remote end user via the serial port, and single-chip GSM engine module is capable of receiving a signal sent from the right , analyzing the signal, and controlling the object.

Vibration Analysis of Cable Suspended Parallel Mechanisms with Dynamic Base Platforms

Yongpan Hu[a], Limin Tao[b]

National University of Defense Technology, Changsha 410073, China;

[a]huyongpan1986@163.com, [b]tlm1964@sina.com

Keywords: Cable suspended parallel mechanism, offshore cargo handling, vibration analysis

Abstract. Cable suspended parallel mechanisms have potential applications in offshore cargo handling. Due to the flexibilities of the cables, the cargo will vibrate under the excitation of wave-induced ship motion. This paper analyzes the vibration of cable suspended parallel mechanisms with dynamic base platforms. Based on the linearization of the dynamic model about a nominal trajectory, the vibration equation is given. The natural frequencies, sensitivities and frequency responses of the mechanism are derived from the vibration equation. Numerical results of an example are discussed, which validate the analysis given by this paper.

Introduction

Cable suspended parallel mechanisms (CSPMs) are a class of cable-driven parallel mechanisms with suspended configurations. One important potential application of CSPMs is offshore cargo handling. Because of the elasticity of the cables, the payload platform inevitably vibrates due to the wave-induced ship motion. Some researchers have studied the vibration characteristics of cable-driven parallel mechanisms with fixed base platforms. For example, Diao and Ma analyzed the vibration caused by cable flexibilities in both axial and transversal directions [1]. Liu et al. determined the natural frequencies and analyzed the sensitivities of the fundamental frequency to structure parameters[2]. However, as far as we know, the vibration characteristics of CSPMs with dynamic base platforms have not been studied yet, which motivates the research in this paper.

Vibration Equation

A general model of a CSPM with m cables is shown in Fig. 1, where $i=1,\cdots,m$. Three coordinate frames F_P, F_B and F_N are fixed to the base platform, the payload platform and the inertial space, respectively. $\mathbf{l}_i \in R^3$ $(i=1,2,\cdots,m)$ is the vector along the ith cable and has the same length as the cable, which is represented by scalar l_i. $\mathbf{e}_i$ is the unit vector along the ith cable.

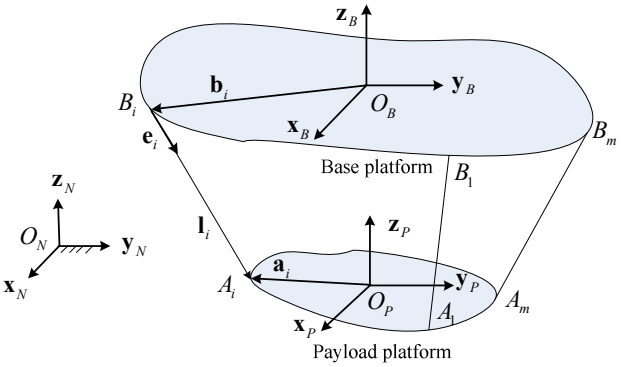

Fig. 1 General model of a CSPR with m cables

Let $\mathbf{t}=(\dot{x},\dot{y},\dot{z},\omega_x,\omega_y,\omega_z)^T$ denote the velocity vector of the payload platform, where $(\dot{x},\dot{y},\dot{z})^T$ is the velocity of O_P and $\boldsymbol{\omega}=(\omega_x,\omega_y,\omega_z)^T$ is the angular velocity of F_P, both represented in F_N. According to the rigid body kinematics [3], we have $\mathbf{t}=\mathbf{H}\dot{\mathbf{x}}$, where

$$\mathbf{H}=\begin{bmatrix}\mathbf{E}_{3\times3} & \mathbf{0}_{3\times3}\\ \mathbf{0}_{3\times3} & \mathbf{h}\end{bmatrix},\ \mathbf{h}=\begin{bmatrix}C\phi C\theta & -S\phi & 0\\ S\phi C\theta & C\phi & 0\\ -S\theta & 0 & 1\end{bmatrix}$$

ϕ and θ are yaw and pitch angles of F_P, $\mathbf{E}$ and $\mathbf{0}$ stand for identity matrix and zero matrix respectively.

On defining $\mathbf{L}=\left(l_1,l_2,\cdots,l_m\right)^T$, the Jacobian matrix can be calculated by $\mathbf{J}=\partial\dot{\mathbf{L}}/\partial\mathbf{t}$. Using Newton-Euler's laws, the dynamic model of the payload platform is formulated as

$$\mathbf{M}\dot{\mathbf{t}}+\mathbf{C}\mathbf{t}-\mathbf{G}=-\mathbf{J}^T\mathbf{u} \tag{1}$$

where

$$\mathbf{M}=\begin{bmatrix}m\mathbf{E}_{3\times3} & \mathbf{0}_{3\times3}\\ \mathbf{0}_{3\times3} & \mathbf{R}_P^N\mathbf{I}\mathbf{R}_N^P\end{bmatrix},\quad \mathbf{C}=\begin{bmatrix}\mathbf{0}_{3\times3} & \mathbf{0}_{3\times3}\\ \mathbf{0}_{3\times3} & [\boldsymbol{\omega}\times]\mathbf{R}_P^N\mathbf{I}\mathbf{R}_N^P\end{bmatrix},\quad \mathbf{G}=\left(0,0,-mg,0,0,0\right)^T$$

m is the mass of the payload platform (including the payload), $\mathbf{I}$ is the 3×3 inertial matrix of the payload platform about O_P, and $\mathbf{u}=\left(u_1,u_2,\cdots,u_m\right)^T$ denotes the cable tensions.

The vibration equation can be obtained from the linearization of (1) about a nominal trajectory. Let $\mathbf{t}_n$ denote the velocity vector of the payload platform on the nominal trajectory. The cables are supposed to be taut all the time and can be modelled as linear springs. We define a function $\mathbf{g}(\ddot{\mathbf{x}},\dot{\mathbf{x}},\mathbf{x})$ as

$$\mathbf{g}(\ddot{\mathbf{x}},\dot{\mathbf{x}},\mathbf{x})=\mathbf{M}\dot{\mathbf{t}}+\mathbf{C}\mathbf{t}-\mathbf{G}+\mathbf{J}^T\mathbf{k}(\mathbf{L}-\mathbf{L}_0)=\mathbf{0} \tag{2}$$

where $\mathbf{L}_0$ means the cable lengths without tension and $\mathbf{k}$ is the stiffness matrix of the cables.

Substituting $\mathbf{x}=\mathbf{x}_n+\delta\mathbf{x}$ into (2) and performing Taylor series expansion about $\mathbf{x}_n$, the vibration equation of the CSPR is derived as

$$\bar{\mathbf{M}}\delta\ddot{\mathbf{x}}+\bar{\mathbf{C}}\delta\dot{\mathbf{x}}+\bar{\mathbf{K}}\delta\mathbf{x}=\bar{\mathbf{f}} \tag{3}$$

where

$$\bar{\mathbf{M}}=\mathbf{M}_n\mathbf{H}_n,\ \bar{\mathbf{C}}=\mathbf{M}_n\dot{\mathbf{H}}_n+\begin{bmatrix}\mathbf{0}_{3\times3} & \mathbf{0}_{3\times3}\\ \mathbf{0}_{3\times3} & [\boldsymbol{\omega}\times]\mathbf{R}_P^N\mathbf{I}\mathbf{R}_N^P-[\mathbf{R}_P^N\mathbf{I}\mathbf{R}_N^P\boldsymbol{\omega}\times]\end{bmatrix}_n\mathbf{H}_n,\ \bar{\mathbf{K}}=\mathbf{J}_n^T\mathbf{k}\mathbf{J}_n\mathbf{H}_n$$

are the 6×6 mass, damping, and stiffness matrices, respectively. $\bar{\mathbf{f}}=-\mathbf{M}_n\dot{\mathbf{t}}_n-\mathbf{C}_n\mathbf{t}_n+\mathbf{G}-\mathbf{S}_n\mathbf{G}$ denotes the equivalent applied force vector. The expressions with the subscript *n* stand for the corresponding variables and formulas on the nominal trajectory.

Vibration Characteristics

The dominating vibration characteristics of CSPMs include natural frequencies, sensitivities and frequency responses. The natural frequencies ω_i and the corresponding modal vectors $\boldsymbol{\varphi}_i$ of the CSPR can be calculated from [2]

$$(\bar{\mathbf{K}}-\omega_i^2\bar{\mathbf{M}})\boldsymbol{\varphi}_i=0 \tag{4}$$

where $i=1,2,\cdots,6$.

Sensitivities reflect the influences of system parameters on natural frequencies, which can be derived from equation (4) as

$$\frac{\partial \omega_i}{\partial p}=\frac{1}{2\omega_i}\frac{(\mathbf{H}_n\boldsymbol{\varphi}_i)^T\dfrac{\partial(\mathbf{J}_n{}^T\mathbf{k}\mathbf{J}_n)}{\partial p}(\mathbf{H}_n\boldsymbol{\varphi}_i)}{(\mathbf{H}_n\boldsymbol{\varphi}_i)^T\mathbf{M}_n(\mathbf{H}_n\boldsymbol{\varphi}_i)}-\frac{\omega_i}{2}\frac{(\mathbf{H}_n\boldsymbol{\varphi}_i)^T\left(\dfrac{\partial\mathbf{M}_n}{\partial p}\right)(\mathbf{H}_n\boldsymbol{\varphi}_i)}{(\mathbf{H}_n\boldsymbol{\varphi}_i)^T\mathbf{M}_n(\mathbf{H}_n\boldsymbol{\varphi}_i)} \tag{5}$$

where p is the symbol that represents any parameter.

Based on the fact that the rotation angles of wave-induced ship motion are small, the equivalent applied force $\bar{\mathbf{f}}$ can be rewritten as

$$\bar{\mathbf{f}}=\tilde{\mathbf{M}}\ddot{\mathbf{x}}'+\tilde{\mathbf{C}}\dot{\mathbf{x}}'+\tilde{\mathbf{K}}\mathbf{x}' \tag{6}$$

where $\tilde{\mathbf{M}}=-\mathbf{M}_n\mathbf{H}_n'$, $\tilde{\mathbf{C}}=-\mathbf{M}_n\dot{\mathbf{H}}_n'-\mathbf{C}_n\mathbf{H}_n'$. It can be seen from equation (6) that the equivalent applied force depends on the mass property of the payload platform, the motion of the base platform and the orientations of the two platforms.

By substituting equation (6) into equation (3) and performing Laplace transform, we have

$$(s^2\bar{\mathbf{M}}+s\bar{\mathbf{C}}+\bar{\mathbf{K}})\delta\mathbf{X}(s)=(s^2\tilde{\mathbf{M}}+s\tilde{\mathbf{C}}+\tilde{\mathbf{K}})\mathbf{X}'(s) \tag{7}$$

Therefore the frequency responses of the cable deformations corresponding to the motions of the base platforms are

$$\mathbf{H}(\omega)=\mathbf{J}_n\mathbf{H}_n(-\omega^2\bar{\mathbf{M}}+j\omega\bar{\mathbf{C}}+\bar{\mathbf{K}})^{-1}(-\omega^2\tilde{\mathbf{M}}+j\omega\tilde{\mathbf{C}}+\tilde{\mathbf{K}}) \tag{8}$$

Numerical Discussion

Vibration characteristics of an example CSPM is analyzed, whose top view is shown in Fig. 2. The base platform and the payload platform of the robot are circular plates with the radii of 0.3m and 0.1m respectively. The distribution parameters of the attachment points are $\alpha=\beta=30^\circ$. Moreover, the mass properties of the payload platform are $m=11.3\,\text{kg}$, $\mathbf{I}=\text{diag}(0.0636, 0.0636, 0.1272)\text{kg}\cdot\text{m}^2$.

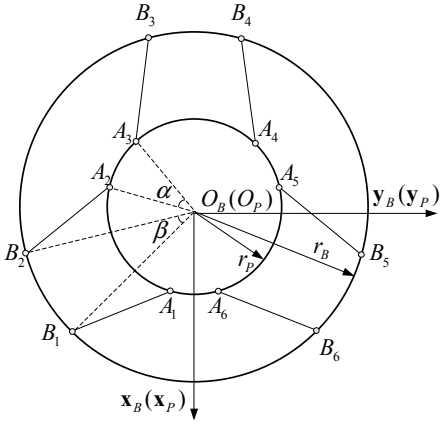

Fig. 2 Top view of the example CSPM

Based on equation (4), the natural frequencies of the example are computed using MATLAB and listed in Table 1. In order to validate the results, a model with the same configuration is built in MSC ADAMS and the natural frequencies are calculated from ADAMS/Vibration, which are also listed in Table 1. It is obvious that the natural frequencies computed from MATLAB and from ADAMS match very well.

Table 1 Natural frequencies of the example CSPM

	Natural frequencies (Hz)					
by MATLAB	3.5172	3.5172	4.7852	19.5508	19.5508	20.3222
by ADAMS	3.5172	3.5173	4.7854	19.5509	19.5510	20.3224

The sensitivities of the fundamental frequency of the example are calculated from equations (5) and listed in table 2. As a reference, small changes are made to the parameters of the model in ADAMS and corresponding variations of the fundamental frequency are recorded, which are used to generate the reference values of the sensitivities. By comparison, the conclusion can be drawn that the results of Table 2 and 3 are identical, which indicates equation (5) is correct.

Table 2 Sensitivities of the fundamental frequency

	$\frac{\partial \omega_1}{\partial \alpha}$ (rad/rad)	$\frac{\partial \omega_1}{\partial \beta}$ (rad/rad)	$\frac{\partial \omega_1}{\partial r_B}$ (rad/m)	$\frac{\partial \omega_1}{\partial r_P}$ (rad/m)	$\frac{\partial \omega_1}{\partial z''}$ (rad/m)	$\frac{\partial \omega_1}{\partial d}$ (rad/m)	$\frac{\partial \omega_1}{\partial m}$ (rad/kg)
by MATLAB	-19.0564	-19.0564	51.8700	27.7796	-47.5234	22262	-1.0002
by ADAMS	-19	-19	52	28	47	22260	-1

The frequency responses of the example are obtained using ADAMS/Vibration and shown in Fig. 3. It is obvious that every line has an extreme point at 3.5172 Hz, which is the fundamental frequency of the CSPM. When the motion frequency is lower than 3.5172Hz, the magnitude responses positively depend on the motion frequency. Therefore, in order to suppress the vibration, the fundamental frequency must be adjusted to be much higher than the motion frequency of the base platform.

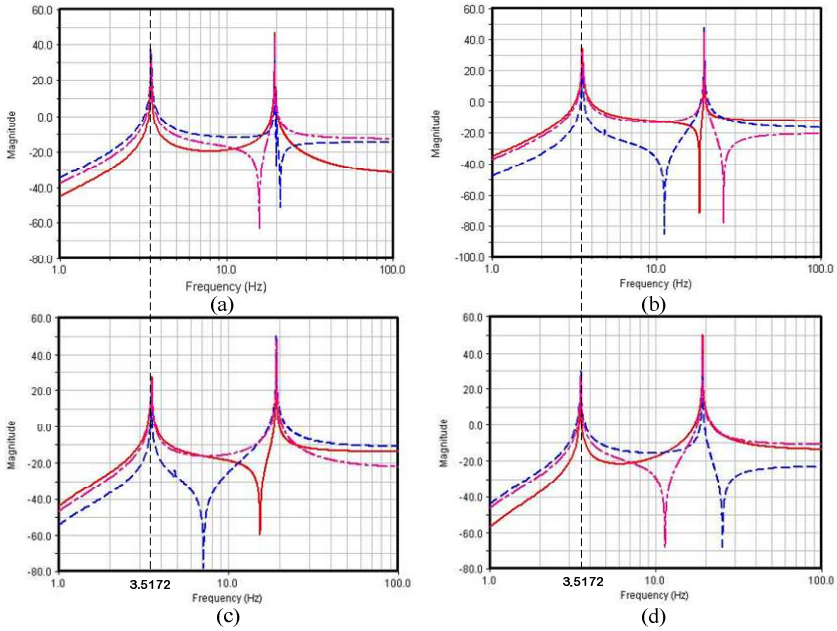

Fig. 3 Magnitude responses of cable deformations relative to (a) the translation along $\mathbf{x}_N$, (b) the translation along $\mathbf{y}_N$, (c) the rotation about $\mathbf{x}_N$, (d) the rotation about $\mathbf{y}_N$, dashed: cable 1 and 6, dashdotted: cable 2 and 5, solid: cable 3 and 4 .

Summary

In this paper, we address the vibration equation and vibration characteristics of CSPMs with dynamic base platforms. The study shows that the vibration induced by the motion of the base platform can be expressed by a vibration equation excited by a equivalent applied force that depends on the motion of the base platform. The vibration characteristics, including natural frequencies, sensitivities and frequency responses are derived from the vibration equation.

Abstract. In the research and development of the precise closed-loop control system in large hydraulic press, the touch screen and PLC are frequently applied to design, debug and test for the system. Though a better closed-loop control characteristic can be acquired after repeated testing by this way, the comprehensive state data of hydraulic press are unable to get, which leads to a long research cycle and also restricts the maintenance and upgrade with the equipment in the later period. In order to obtain the whole state information of hydraulic press easily and effectively, a monitor system of precise closed-loop control in large hydraulic press is designed. Based on reasonable cooperation of sensors and high-speed data-acquisition card, high-speed and precise signal acquisition is realized. In addition, data-acquisition software program is designed base on LabVIEW, it can achieve the functions of collecting, storing, displaying and analyzing data. Through the real measuring and analyzing on a certain large ceramic hydraulic press, the status of key parameters can be acquired effectively during the whole pressing process. So the monitoring system supplies the significant data basis to the precise closed-loop control, accelerates the design and development of high characteristic precise closed-loop control and also strongly supports to the maintenance and upgrade with the equipments in the later period.

Introduction

The large hydraulic press is important equipment in mechanical industry, which usually improves the mechanical property and rate of finished products by means of multi-stage compressions during pressing process [1]. Every pressing process concludes the position closed-loop control, velocity closed-loop control or pressure closed-loop control and so on. The measurement and control system is generally the teamwork of touch screen and PLC, the precise closed-loop control is realized through repeated testing of control parameters and modes in the touch screen. Although the precise control can be achieved in some extent, some problems still exist in rapid debugging and the highly precise control in closed-loop system.

Aiming at the teamwork of PLC and touch screen, on the basis of the above mentioned the realization of accurate and efficient closed-loop control testing and analysis are facing two technological difficulties. Firstly, the large hydraulic press needs multi-stage compressions and the working condition of pressing process is complex, measurement and control system of conventional large hydraulic press can't be visualized and observed with the core parameters directly. Depend on these, it is not clear of the comprehensive characteristic of hydraulic press, and it cannot be conduct contrastive analysis, which leads to a long cycle and low efficiency of design, development and testing. Secondly, the large hydraulic press proposes extremely demand on the signal quality during precise closed-loop control, especially the feedback signals of sensors. Millivolt voltage fluctuation or noise disturbance could cause the control precision reducing. Nowadays, the display method relies

on touch screen that cannot get the accurate data of signal, so that the signal processing and higher precision control are restricted. Due to the above two technological difficulties, the system of conventional hydraulic press is hard to realize efficient and accurate closed-loop control. Therefore the design of monitoring system, reflecting hydraulic press comprehensive characteristic, is especially important.

This paper takes the certain large ceramic hydraulic press as an example, on the basis of analyzing its operating principle and every key parameter, the monitoring system based on LabVIEW is designed [2]. The precision characteristics and model selection of sensors and data acquisition equipment are analyzed to meet monitoring system, and the software system based on LabVIEW is designed, which realize the collecting, storing, real-time displaying and analyzing the key parameters of hydraulic press, it provides the data support for realizing the efficient and accurate closed-loop control of hydraulic press [3].

Working Principle

Take a certain model of hydraulic press for example, the electro-hydraulic control technology is applied to achieve the accurate press of master cylinder and promise the precise shaping of ceramic product. The whole press process mainly includes three stages: fall of master cylinder, press stage and return stage. The press stage is the key process of compression moulding, it can divide into first press and exhaust, second press and exhaust and third press stage shown in Fig. 1. In order to realize the rapid, accurate and steady press during the compression moulding, electro-hydraulic proportional/servo closed-loop control method is adopted, and the closed-loop control method generally contains position closed-loop, like fall of master cylinder, pressure closed-loop, like first press and position-pressure compound closed-loop control and so on.

Hydraulic press closed-loop control method is the feedback control system based on feedback single acquired by position sensors and pressure sensors. The monitoring system established by LabVIEW can ensure the precise measurement and control of hydraulic press in each state. Closed-loop control in hydraulic press operation concludes following stages. Firstly, in fall of master cylinder stage, the pressure in master cylinder is so low that it is unnecessary to build pressure measure system. For rapidly falling down and steady touching powder, the position closed-loop of tracking deceleration curve is applied, and the position monitoring is extremely important at this time. Then, in order to improve the product mechanical property and rate of finished products, the pressure closed-loop control method is employed in the press process, especially the first press. The pressure in master cylinder is monitored by the high precision pressure sensor and precise closed-loop control is realized, which can avoid the poor compression moulding quality caused by too high or low pressure. Meanwhile, considering that the plane pressed by hydraulic press is large, uneven forcing leads to uneven product thickness in the press process. The plane absolute position is monitored via the position sensors beside the both side of master cylinder, so the high precision plane press of master cylinder is achieved. Finally, in the phase of master cylinder raising depended on hydraulic pressure, the request of position precision is lower at this stage, only needs the position sensor monitor the detail position for next cycle.

By above hydraulic press working process, precise closed-loop control of large hydraulic press must have a mass of pressure, position and velocity data as the support. Therefore, a monitoring system of whole state data base on LabVIEW is significant for condition monitoring, fault diagnosis and precise closed-loop control of hydraulic press [4].

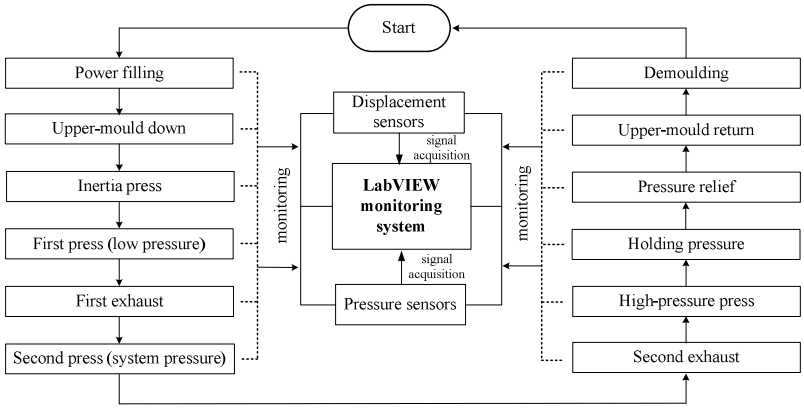

Fig. 1 The working principle of large hydraulic press

The Design of Overall Program of Monitoring System Based on LabVIEW

The overall program of monitoring system based on LabVIEW for large press is shown in Fig. 2. By analyzing the working principle, it shows that the master cylinder of hydraulic press, boosting cylinders, control valves and other components are involved in precise closed-loop control. The pressure and displacement sensors are installed to detect the key parameters of status signals in each component. Combining with hardware filtering, the data is acquired by acquisition card via signal shielded cable, then LabVIEW test software systems are installed in the industrial personal computer for testing, analysis and displaying. So we can operate the monitoring and control system with the man-machine interface in the display terminal.

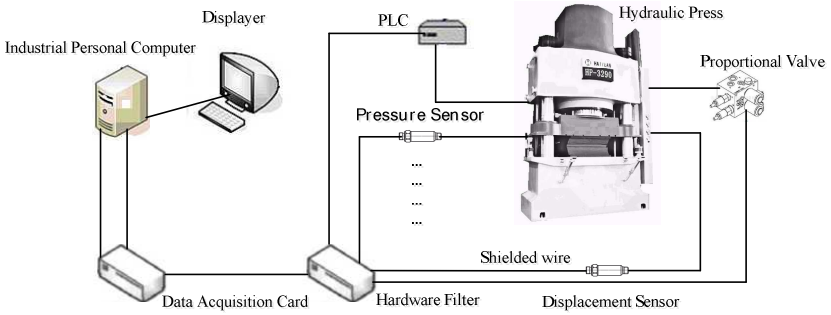

Fig. 2 The overall program of monitoring system based on LabVIEW for large hydraulic press

Hardware Design. According to the working principle and the overall program as shown in Fig. 2, the data monitoring system needed to test mainly involves the system pressure, the left displacement of upper mould, the right displacement of upper mould, the pressure in master cylinder rodless chamber (under chamber), displacement of master cylinder, proportional valve spool displacement in rod chamber(upper chamber), the proportional valve spool displacement in under chamber, command signal and other system status signals. Measured signals are mainly displacement and pressure signals, so pressure or displacement sensors can be selected. Each signal and sensor parameter is shown in Table 1. The USB high-speed data acquisition card of Advantech 4711A can be applied to data collection. Appropriate equipments are shown in Fig. 3.

Table 1 The key signals and parameters of sensors

Measured target	Measuring range in sensor	Output Signal	Measured target	Measuring range in sensor	Output Signal
system pressure	0~250bar	0~10V	displacement of boosting cylinder	0~450mm	0~10V
left displacement of upper mould	0~300mm	4~20mA	displacement of upper proportional valve spool	0~5mm (two-direct)	0~10V
right displacement of upper mould	0~300mm	4~20mA	displacement of under proportional valve spool	-5~5mm (three-direct)	-10~10V
pressure in boosting cylinder	0~400bar	0~10V	command signal	-10~10V (PLC)	-10~10V

Fig. 3 The data acquisition hardware of hydraulic press monitoring system

In the monitoring and control system of the large hydraulic press, the displacement signal of proportional valve spool in the upper chamber and under chamber is transmitted to PLC by 7 pin terminal in proportional valve amplifier. So the data acquisition card could acquire data directly via analog inputs of the PLC. The command signal of the closed-loop control system can also be transmitted from the PLC analog output terminals to data acquisition card. The selected Advantech 4711A card has 16 analog input channels, and it can achieve 8 differential voltage inputs. The left displacement of upper mould and the right displacement of upper mould signal are current signals, which can be converted to voltage signals collection through a 250Ω precision resistance. Therefore, the corresponding key parameters and data can be transmitted in a unified way of differential voltage input to the AI ports of the data acquisition card. For achieving high-quality signal acquisition, it connects sensors, PLC and data acquisition card through shielded cable and adds low-pass filters with cut-off frequency of 200Hz to each channel to eliminate noise interference. The IPC and data acquisition card could realize data acquisition, storage, display, analysis and other functions via connecting USB port [5].

The Design of Software System. Software system contains configuration management software and application development software. Configuration management software is mainly used for hardware identification and information interaction with all data acquisition cards. Application development software exploits the software base on graphical programming platform [6]. After configuring and debugging the testing system hardwares, data acquisition modes will be set through configuration management software. In this paper, we set all the channels as differential input mode, and then develop the required application software based on LabVIEW.

The software system structure and flow base on LabVIEW is shown in Fig. 4, and its primary functions include data acquisition, data saving, data analysis, real-time display and so on [7]. Firstly, all acquisition channel parameters are configured on the LabVIEW system plane of IPC base on the data in Table 1. Secondly, data acquisition begins and the data acquisition card sends the single measured by the sensor to the LabVIEW system. Then, single processing function is applied to display the data in real-time as required on the IPC, and if saving is needed, click on the save button to store data. Finally, to further detail analysis, storing data can be paged out for more precise and comprehensive analysis. The above methods can be efficiently used to realize data acquisition, storing, real-time displaying and analyzing all state data of large hydraulic press.

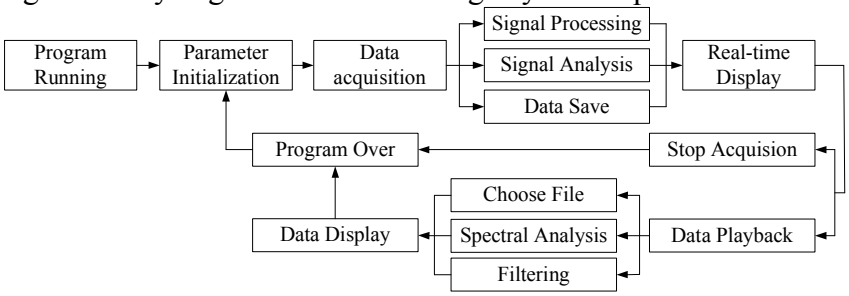

Fig. 4 The software system structure and process base on LabVIEW

In order to realize all state monitoring, the main program of software system base on LabVIEW is designed, and the front panel is shown in Fig. 5. It mainly includes setting parameters, starting acquisition, stopping acquisition, saving data, displaying data, stop and so on. Based on LabVIEW, the overall framework of main program is that the While loop structure is used to achieve the function of data acquisition and the Event structure is used to achieve the functions of setting parameters, saving data, displaying data and so on [8].

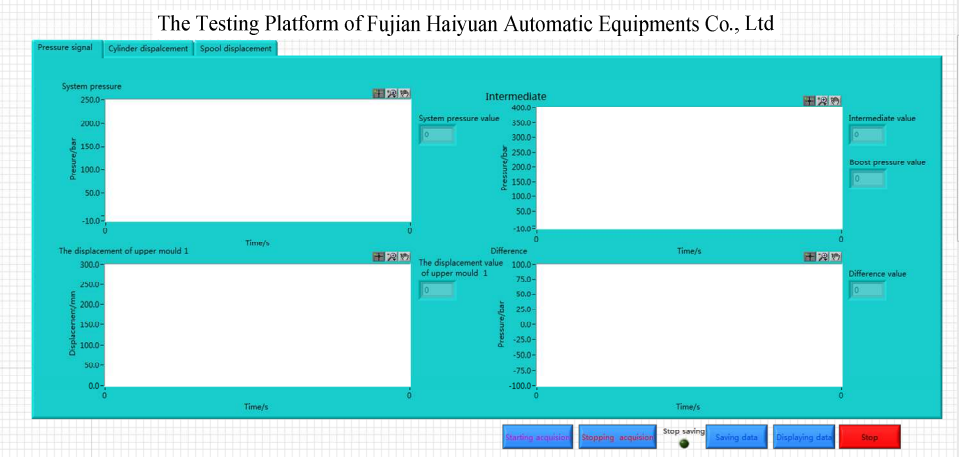

Fig. 5 The main program interface of status monitoring

A. Parameters setting. Before data acquisition, the channel parameters of acquisition card need to be firstly configured, and the front panel of subprogram used to set system parameters is shown in Fig. 6. The sampling rate in the front panel is the sum of each channel sampling rate, and the system sample rate is set to 8 kS/s. The sum of all channels is 8, from channel 0 to channel 8, and the sampling rate of each channel is set 1 kS/s, which ensures that the sum of the sampling rate in all channels is no more than 150 kS/s. The maximum count can be set up to the half of Advantech 4711A acquisition card FIFO (First in, first out), which is 512. BufferSize is the cache that user creates on the computer's memory, and it should be set the integer times of the product between the count and channel number, that is to say 4096=1×512×8. The input voltage range can be identified by each analog input channel, which is set by the code in gain list. The gain codes in all channels are set 4 in this paper, so all the input voltage ranges are ±10V.

Fig. 6 The front panel of parameters setting

B. Starting acquisition. When user chick on the button of ‘starting acquisition’ in the front panel, the program goes into the acquisition cycle and begins to read voltage value from each channel. In order to ensure that the data display and storage process will not affect the speed of reading data and avoid data loss, the producer-consumer structure is applied by the overall structure of acquisition program, whose program chart is shown in Fig. 7. After the producer cycle reads voltage value through subprogram from each channel, the data will be written into the queue. After the consumer cycle reads the data from the queue and converted them to the corresponding parameter values, the date will be displayed on front panel, and the data is stored in a temporary file by the TDMS format at the same time.

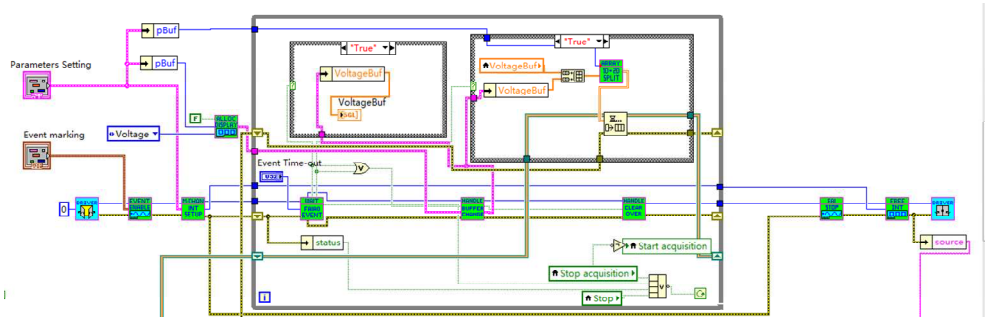

Fig. 7 The producer–consumer cycle of real-time monitoring program

C. Stopping acquisition. When user click on the button of ‘stopping acquisition’, acquisition cycle will be stopped and idle loop begins to execute.

D. Saving data. At the same time of data acquisition, data has been saved to a temporary file. If users need to save the current data, click 'Save' button on the front panel, then program executes corresponding event structure. Then the data is saved under the folder which has the same name with principal program path. Data file name is constituted with the name input by user on the front panel and current system time, and the program chart is shown in Fig. 8. If you do not need to save the current data, data in a temporary file will be overwritten when executing data acquisition next time.

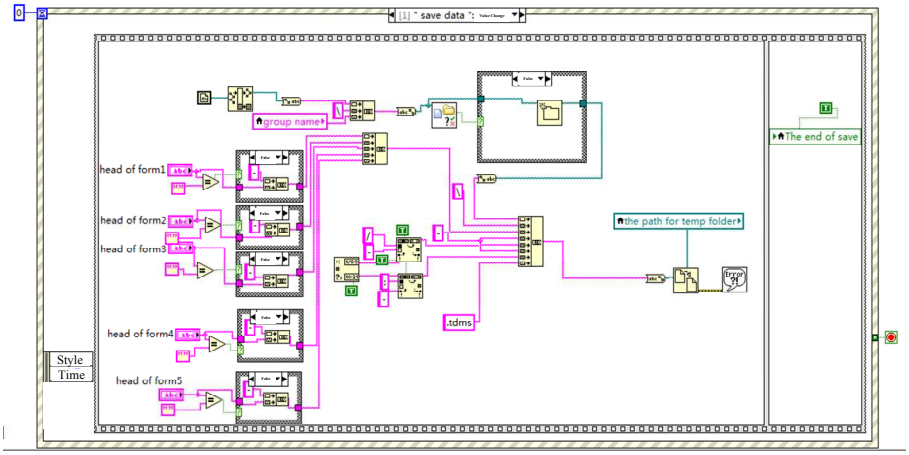

Fig. 8 The program of saving data

E. Displaying data. When the user clicks on the 'Data Display' button on the front panel, the program will execute the corresponding event and the popping subroutine front panel that displays the data is shown in Fig. 9. In the default circumstance, this subroutine has always scanned the file in the 'Test Data' folder and all the data files with suffix of '.tdms' are added to the 'Choose File' combo box for users to choose and observe. After the user selects the data file, user can check the options on the left of waveform diagram to show the corresponding curves, and similarly the name of curves on the right of waveforms diagram will be updated. In addition, users can also filter the curves, and the filtering frequency can be input by the user in the subroutine front panel. When you click 'Stop' button, the subroutine exits and the front panel is off automatically.

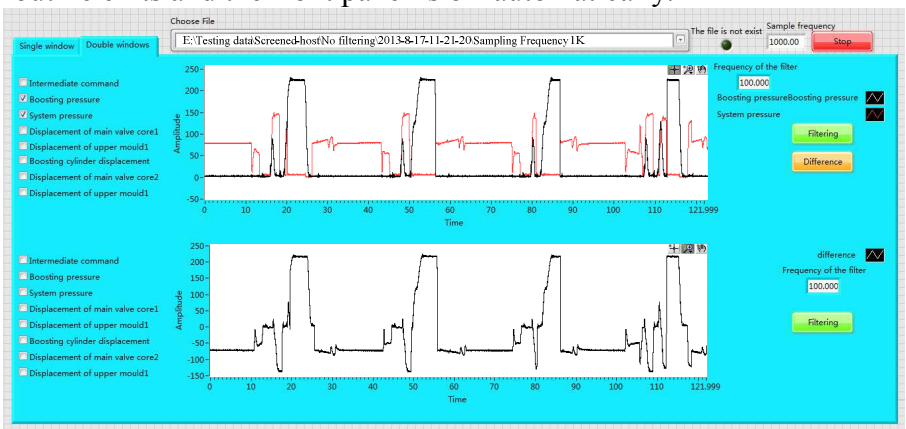

Fig. 9 The program of displaying data

F. Stop. When user click on the button of 'Stop', all applications will stop running no matter what the current operation state is.

Experiment and analyze of key parameters in large hydraulic press

The above data acquisition system based on LabVIEW is applied to monitor the working conditions in a large ceramic hydraulic press, and the data acquisition, real-time display and analysis of key parameters can be realized effectively [9]. This monitoring system can effectively acquire the status of system pressure, the pressure in master cylinder under chamber, displacement of master cylinder, proportional valve spool displacement in upper chamber, the proportional valve spool displacement in under chamber, command signal and so on. Fig. 10 and Fig. 11 respectively indicate the pressure in

master cylinder under chamber and proportional valve spool displacement in upper chamber with a certain type of ceramic hydraulic press, and all the curves contain only a single cycle.

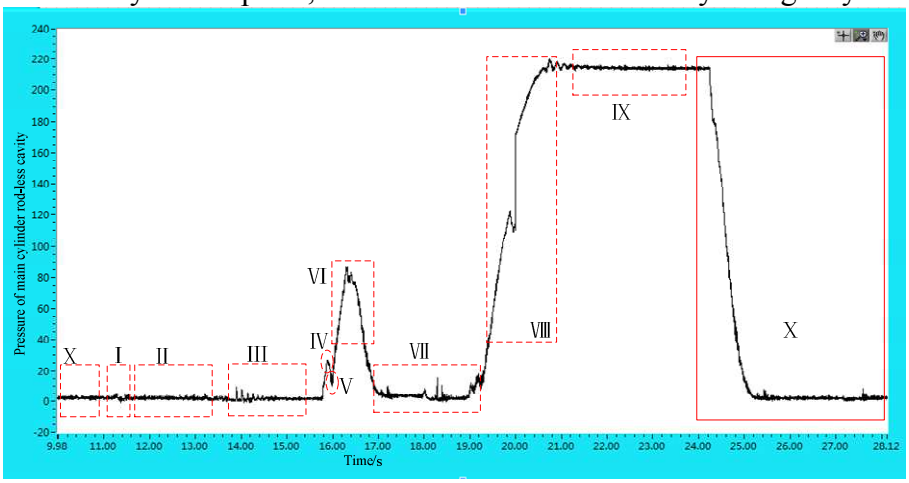

Fig. 10 The pressure curve of master cylinder in under chamber

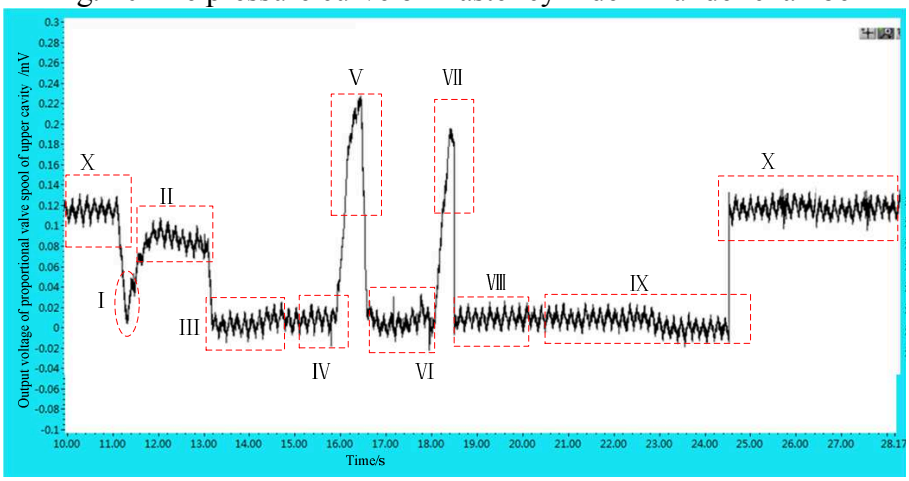

Fig. 11 The proportional valve spool displacement curve in upper chamber

The curves in Fig. 10 and Fig. 11 respectively show that the pressure of master cylinder in under chamber and the proportional valve spool displacement in upper chamber. The voltage value 0.12V in Fig. 11 represents that the three-way proportional valve is in neutral position. If the voltage value increases, the master cylinder will move up because the upper chamber of the master cylinder is imported high pressure oil. On the contrary, when the voltage value is decreased, the master cylinder will fall down because the oil in upper chamber of the master cylinder returns back to tank. So the voltage value indicates the size of the valve opening.

Firstly, the stage of the master cylinder falling down includes the fast falling stage Ⅰ and the slow falling stage Ⅱ, and at this moment the pressure in under chamber of master cylinder was low. Due to three-direct proportional controlled valve controlling oil in upper chamber to return to tank, the larger of the proportional valve spool opening, and the faster of master cylinder falling. Secondly, the press began inertial pressing stage Ⅲ and the master cylinder relayed on its dead weight for pressing. Similarly pressure of the under chamber was also low, and oil in upper chamber continues returning back to tank. Thirdly, it was the first press stage Ⅳ, and the pressure in under chamber was raised to about 25 bar. After that it would turn to the first exhaust stage Ⅴ, and in this moment the upper chamber linked with the high pressure oil would cause the main cylinder lifting a little for the first exhaust and the pressure in under chamber would reduce. Fourthly, when the first exhaust was finished, the press came into the second press stage Ⅵ, and that moment the pressure in under chamber was consistent with the system pressure, so the master cylinder was pressurized by the system pressure directly. And then the pressing process was transferred to the second exhaust stage Ⅶ, the pressure in under chamber will relief to 0 bar, and the main cylinder raised through connecting

high pressure oil with the upper chamber. Finally, booster stage Ⅷ indicates the booster cylinder pressurized the cylinder rodless chamber to the highest pressure. After the maintaining pressure stage Ⅸ and the pressure relief stage Ⅹ, the highest pressure dropped to 0bar.

Obviously, we can observe every running state of the press clearly according the above curves, and we also can deeply check the changing relationship between the states simultaneously to the pressing characteristics during the pressing process. The maintenance, upgrade and diagnosis of the large hydraulic press can be effectively achieved based on the measured data.

Conclusions

The monitoring system based on LabVIEW was designed for precise closed-loop control of large hydraulic press, and it is a method to acquire full state data of the press simply and effectively. The functions of the system include data acquisition, data saving, real-time display and process analysis and so on. The process data of the hydraulic press can be effectively recorded and saved, to lay the foundation for the establishment of a database system of the large hydraulic press.

The monitoring system can obtain the key parameters data of the pressing process and curves effectively, which can be used to analyze and correct the control system based on the data. It will improve the precision and efficiency of designed closed-loop control system and short the development cycle. The system has achieved good test and analysis results that applied in a certain type of large ceramic press, which can provide strong support for the subsequent equipment maintenance, fault diagnosis and the system upgrade.

Keywords: Geostress, Excavation, Numerical Simulation, Slope Stability, Deep Open Pit.

Abstract. Further excavation is extraordinary significant to the sustainable development of mine. For the rock slope, three-dimensional geostress in the deep mining area are presented complex and high, which were caused by previous excavation. Also, it is important to obtain the accurate geostress in mining area, which is the necessary precondition for determining the remaining ore mining scheme and the slope stability. In this paper, based on the in-situ geostress monitoring date, a 3D numerical model alongside the physical dimensions was built in finite element software FLAC3D, to accept the constitutive parameter and monitoring data, to predict the 3D stress and displacement distributions and detail failure information, to estimate stability of mining area.

Introduction

With the fast development of the mining technique, also, further excavation is extraordinary significant to the sustainable development of mine. In china, there are a huge number of mines adopted the Open-pit mining method [1]. And as long as the enlarging production scale and the mining excavation depth, the high and steep slope, whose stability is important and difficult manageable, must be increasing continually [2]. According to the statistics, in china, from 15% to 20% high and steep slopes are the unstable slopes or potential unstable slopes [3]. Hence, it is extremely urgent problem to be researched on the slope stability in the deep open pit. Although, many scholars have done huge efforts on the excavation and slope stability all the world. Lilly and Li (2000) estimated the excavation reliability by using the displacement modeling [4]; Sheng et.al., (2002) estimated the excavation disturbed zone in the permanent shiplock slopes [5]; Li et.al., (2007) used a Face-to-Face discrete element method to analyze the critical excavation depth for a jointed rock slope [6]; Cheng et.al., (2012) adopted the CFS theory to analyze the steep excavation slope failure [7]; Guo and Cheng (2013) had a consideration on group excavation engineering [8]; Guo et.al., (2013) did the research on the deformation stability of soft rock slope under excavation based on FLAC3D [9]; Hsieh et.al., (2013) used the three-dimensional numerical analysis of deep excavations with cross walls [10]; Wang et.al., (2014) did the research on the loess landslide induced by excavation and rainfall[11]. For the deep and steep rock slope in the metal mine, as the increasing of depth, the geostress are becoming huge and complex, which will generate a remarkable impact on the slope stability. In this paper, based on the in-situ geostress monitoring date, a 3D numerical modeling was built in finite element software FLAC3D alongside the real size of open air slope, to accept the constitutive parameter and monitoring data, to predict the 3D stress and displacement distributions, to determine the sequence of excavation and estimate the stability of mining area.

Engineering Background and In-situ Geostress

Engineering Background. In this paper, Shuichang open pit iron mine was chosen as the engineering background, it is a large typical magnet ore deposit with metamorphic rock, and locate in Qianan city, Heibei province. Now, the mining scale is the 11 million tons per year. And the elevation of stope bottom is -136.38m at present, and it will be excavated to the level of -440m in further. Based

on the real engineering situation, the particular models were built in software FLAC3D as shown in figure 1 and 2.

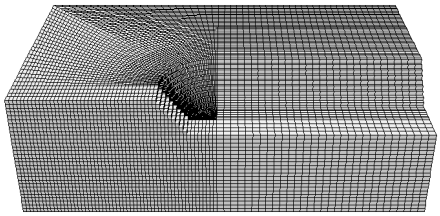

Fig. 1 The elevation of bottom with -136m

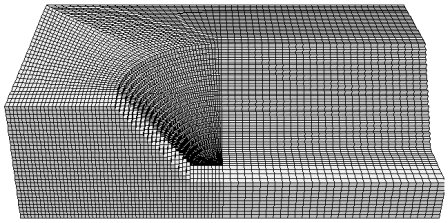

Fig. 2 The elevation of bottom with -440m

In the model, X axis was the horizontal direction along the long edge, and along the short edge direction, the horizontal direction was Y axis, The Z axis was vertical direction. And the length, width and height are respectively2900m, 1400m and 900m by according to the real size of the open pit. The finite element mesh consists of 14541 nodes and 138000 elements.

Constitutive parameter. Form the top to the bottom, there are 5 layers, which are artificial miscellaneous filled soil, sandstone, mudstone, magnetite and mixed granite, whose constitutive parameters were obtained from the lab test, as shown in table 1.

Table 1 Particular constitutive parameters of rock

Layer	Density （kg/m3）	E(MPa)	υ	bulk modulus (Mpa)	shear modulus (Mpa)	friction angle （°）	cohesion (Mpa)
Filled soil	2000	20	0.300	16.7	7.69	18	0.13
Sandstone	2570	9512	0.26	6605	3774	39	0.485
Mudstone	2510	1650	0.36	1964	610	30	0.31
Magnetite	3200	12500	0.23	7720	5080	40	0.917
Granite	2604	7130	0.24	4570	2880	49	0.646

In-stiu geostress. Based on the in-situ monitoring geostress data, after analysis and calculation, the relationship between the geostress and depth was shown from formula (1) to (3).

(a) The maximum horizontal geostress,

$$\sigma_{h.\max} = 0.93 + 0.0438H \quad (MPa) \tag{1}$$

(b) The minimum horizontal geostress,

$$\sigma_{h.\min} = 0.61 + 0.0269H \quad (MPa) \tag{2}$$

(c) The vertical geostress,

$$\sigma_v = 0.12 + 0.0259H \quad (MPa) \tag{3}$$

Where, H is the depth (m).

Numerical Simulation

Constitutive Model. According to the characteristics of each rock layer, in this simulation, the Mohr-Coulomb failure criterion with tension cut off were employed as constitutive model. It was expressed as the well-known formula below [12],

$$\sigma_1 \geq \sigma_2 \geq \sigma_3 \tag{4}$$

where, $\sigma_1, \sigma_2, \sigma_3$ respectively are the major principal stress of the elements, And the Mohr-Coulomb criterion can be represented in the plane (σ_1, σ_3), the failure envelope $f(\sigma_1, \sigma_3) = 0$, so $f^s = 0$ with

$$f^s = \sigma_3 - \sigma_1 N_\phi + 2c\sqrt{N_\phi} \tag{5}$$

A tension failure criterion of from $f^t = 0$ with

$$f^t = \sigma_1 - \sigma^t \tag{6}$$

Where ϕ is the friction angle, c is the cohesion, σ^t is the tensile strength, and

$$N_\phi = \frac{1+\sin\phi}{1-\sin\phi} \tag{7}$$

So the potential function is described by means of two functions, Q^s is the shear potential function, is

$$Q^s = \sigma_3 - \sigma_1 N_\psi \tag{8}$$

Where ψ is dilation angle, and $N_\psi = \frac{1+\sin\psi}{1-\sin\psi}$.

Q^t is the tensile potential function, is

$$Q^t = -\sigma_1 \tag{9}$$

Excavation Scheme. In order to simulate the real excavating form, in this model, the excavation with 10 steps was carried out. The height of each step was 60m, the particular form of excavating steps as depicted in figure 3

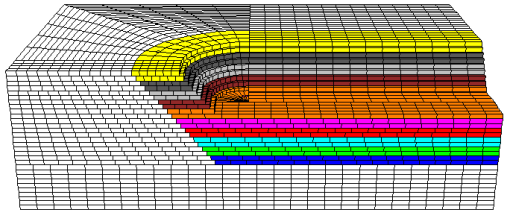

Fig. 3 Particular form of excavating steps

Simulation Results. After simulation, the results of the X, Y, Z displacement were illustrated in figure from 4 to 6, and the typical profile of displacement as depicted in figure 7

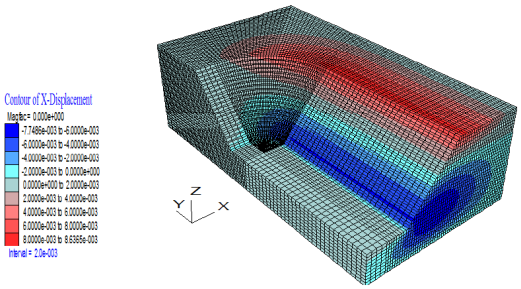

Fig. 4 3D X-displacement contour

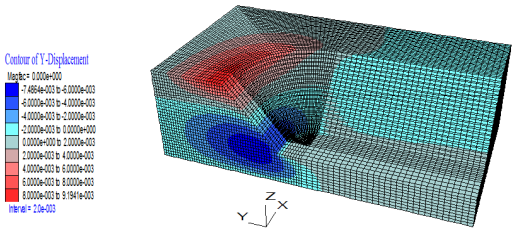

Fig. 5 3D Y-displacement contour

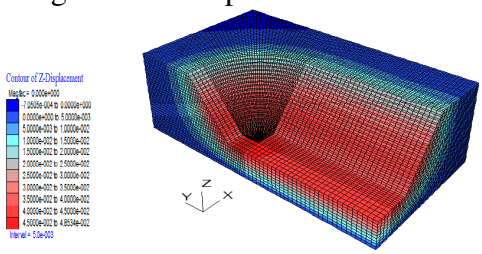

Fig. 6 3D Y- displacement contour

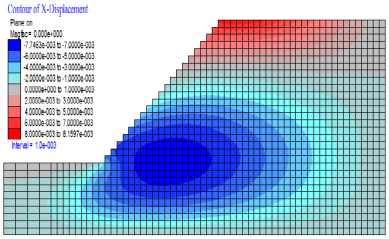

Fig. 7 Y=-800m typical profile contour

From the figure 4 to 6, the maximum positive (direction of pointing to the stope) horizontal displacement after excavation, which was caused by excavating to lead the stress springback and redistribution, appeared at the foot of slope. And the negative (reverse direction of pointing to the stope) horizontal displacement, due to weak strength of miscellaneous filled soil, occurred at the top of slope. And the vertical displacements had relationship with cover depth, due to the weight of the covered rock mass.

For the principal stress, the particular contour and typical profile contour were indicated in figure 8 to 9.

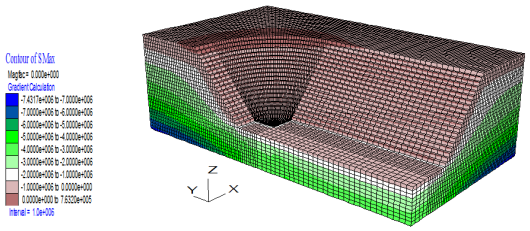

Fig. 8 The maximum principal stress contour

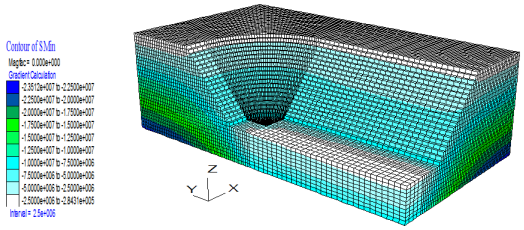

Fig. 9 The minimum principal stress contour

As shown in figure 8, the maximum principal stress was following the basic law, which was increasing from top to bottom with gradient. The maximum principal stress on the surface of slope was zero, due to the free boundary. Also, there was a small tensile stress zone with the 100m width and 50m depth on the top of slope at the corner of model, the value was 0.36 Mpa, other part was compressive stress zone. For the minimum principal stress as shown in figure 9, it also had the same law with the maximum principal stress, except, there is not tensile stress zone all over the slope model.

In order to obtain the detail information of the damage, typical profiles of plastic failure zone were necessary, which were extracted from the simulation model, as shown in figure 14 and 15.

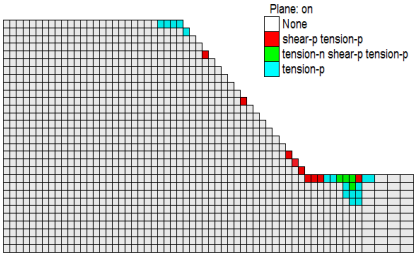

Fig. 14 Typical profile at the corner

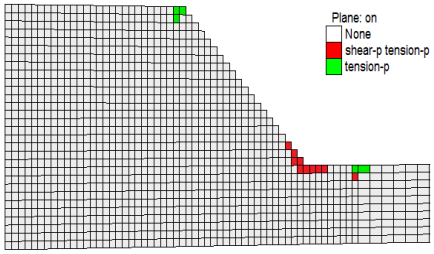

Fig. 15 Typical profile at X=-150m

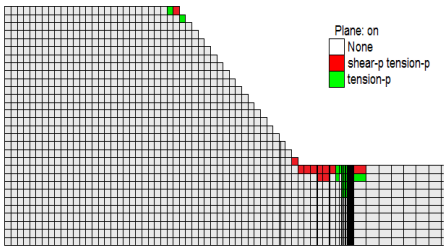

Fig. 14 Typical profile at X=-110m

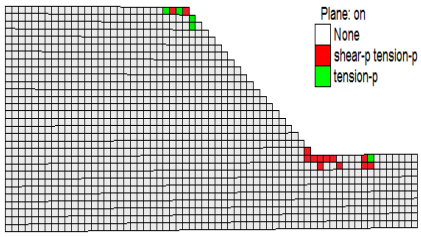

Fig. 15 Typical profile at X=-70m

As shown in the above typical profile, because, the larger tensile stress and weaker strength of the soil, there was a tension failure zone with 50m to100m width on the top of the slope closing to slope surface. And there was a shear damage zone at the foot of slope, due to the excavation, to lead the geostress was redistributed, the range was about 200m width and 50m depth.

Summary

(1) In order to analyze the stabilty of slope, it is important to monitor the accurate geostress in mining area, which are the necessary precondition for determining the remaining ore mining scheme and the slope stability.

(2) Based on the displacement analysis, the miscellaneous filled soil and the sandstone at the location of top slope closing to slope surface, should be support by a reinforcement measure. And at the foot of slope, there also had some rock falls off phenomenon, which was caused by the stress redistribution and springback.

(3) As shown in foregoing contour of stress, the maximum principal stress and the minimum principal stress both were following the basic law, which was diminishing form bottom to top. The stress on the surface of slope was zero, due to the free boundary. And there was a small tensile stress zone in the superficial layer of slope, which would lead to some partial tensile failure, the force would be easy to cause the rock falling off, hence, it is necessary to pay attention to fallen stones which would threaten

the safety of people and equipment working under this area but this tensile could not produce enough impact on the stability of the whole slope.
(4) Based on the foregoing analysis of typical profile of plastic failure zone, in detail, there also was a tension failure zone with the width 100m scope on the top of the slope in every figure. And there was a shear damage zone at the foot of slope with 200m width, which given a detailed analysis of the slope stability.

Keywords: high-rise building, static pushover, improved capacity spectrum method.

Abstract. In this paper, a new analysis model to assess the structure seismic capability is established, using improved capacity spectrum method. The model can solve the problem of many unknown and big computation workload in the process of conventional Pushover analysis. Conventional Pushover is very complex when use in the analysis of structure dynamic problem and nonlinear problem, the new model can solve these problem.

Introduction

Static elasto-plastic seismic analysis of Pushover method to evaluation of the structure of the anti-seismic ability, mainly have the following steps: Firstly make the base shear-top floor displacement curve and translated into power spectrum; then determine the demand spectrum under the action of earthquake, according to the seismic intensity, site classification, structure period and damping ratio; the capacity spectrum and demand spectrum will be drawing in the same coordinate system, and get the intersection point, which called performance point; at last the displacement of performance point is transfer into the target displacement of structure, and comparing with the permissible value. So we can evaluate aseismic deformation capacity of structure.

Basic principles

Spline discretization. Discrete the plane projection of the structure under the bidirectional spline node, using spline basis function and the orthogonal polynomial linear combination structure to product the overall displacement field, the displacement function is:

$$
\begin{aligned}
u &= \sum_{m=1}^{R}\sum_{i=0}^{N}\sum_{j=0}^{M}\phi_i(x)\psi_j(y)a_{ijm}X_m(z) = \sum_{m=1}^{R}\left[\phi(x)\right]\otimes\left[\psi(y)\right]\left\{a\right\}_m X_m(z)\\
v &= \sum_{m=1}^{R}\sum_{i=0}^{N}\sum_{j=0}^{M}\phi_i(x)\psi_j(y)b_{ijm}Y_m(z) = \sum_{m=1}^{R}\left[\phi(x)\right]\otimes\left[\psi(y)\right]\left\{b\right\}_m Y_m(z)\\
w &= \sum_{m=1}^{R}\sum_{i=0}^{N}\sum_{j=0}^{M}\phi_i(x)\psi_j(y)c_{ijm}H_m(z) = \sum_{m=1}^{R}\left[\phi(x)\right]\otimes\left[\psi(y)\right]\left\{c\right\}_m H_m(z)\\
\theta_x &= \sum_{m=1}^{R}\sum_{i=0}^{N}\sum_{j=0}^{M}\phi_i(x)\psi_j(y)d_{ijm}\Theta_m(z) = \sum_{m=1}^{R}\left[\phi(x)\right]\otimes\left[\psi(y)\right]\left\{d\right\}_m \Theta_m(z)\\
\theta_y &= \sum_{m=1}^{R}\sum_{i=0}^{N}\sum_{j=0}^{M}\phi_i(x)\psi_j(y)e_{ijm}S_m(z) = \sum_{m=1}^{R}\left[\phi(x)\right]\otimes\left[\psi(y)\right]\left\{e\right\}_m S_m(z)\\
\theta_z &= \sum_{m=1}^{R}\sum_{i=0}^{N}\sum_{j=0}^{M}\phi_i(x)\psi_j(y)f_{ijm}T_m(z) = \sum_{m=1}^{R}\left[\phi(x)\right]\otimes\left[\psi(y)\right]\left\{f\right\}_m T_m(z)
\end{aligned}
\tag{1}
$$

$\phi_i(x)$, $\psi_j(y)$ is the discrete spline function of x,y direction respectively, $X_m(z)$, $Y_m(z)$, $H_m(z)$, $\Theta_m(z)$, $S_m(z)$ and $T_m(z)$ is the orthogonal polynomial of structure along the height.

$$X_m(z) = \sum_{n=1}^{m} (-1)^{n-1} \frac{(m+n)!}{(m-n)!(n+1)!(n-1)!} \left(\frac{z}{H}\right)^n$$
$$Y_m(z) = H_m(z) = \Theta_m(z) = S_m(z) = T_m(z) = X_m(z) \tag{2}$$

Type (1) written in matrix :

$$\{V\} = [N]\{\delta\} \tag{3}$$

The dynamic equations of structures. The whole structure is divided into p unit, total potential energy functional for the structure is:

$$\Pi = \sum_{e=1}^{p} \Pi_e = \sum_{e=1}^{p} \frac{1}{2} \{V\}^{eT} [k]^e \{V\}^e - \{V\}^{eT} \{f\}^e - [\mathrm{c}]^e \{\dot{V}\}^e - [\mathrm{m}]^e \{\ddot{V}\}^e \tag{4}$$

Formula(3) into (4):

$$\Pi = \frac{1}{2} \{\delta\}^T [K] \{\delta\} - \{\delta\}^T \{F\} - [C] \{\dot{\delta}\} - [M] \{\ddot{\delta}\} \tag{5}$$

$[K]$ is the total stiffness matrix, $[M]$ is the total mass matrix, $[C]$ is the total damping matrix, $\{F\}$ is The total load vector:

$$[K] = \sum_{e=1}^{p} [K]^e \quad \{F\} = \sum_{e=1}^{p} \{F\}^e \quad [M] = \sum_{e=1}^{p} [M]^e \quad [C] = \sum_{e=1}^{p} [C]^e$$
$$[K]^e = [N]_e^T [T]^{eT} [k]^e [T]^e [N]_e \quad [M]^e = [N]_e^T [T]^{eT} [m]^e [T]^e [N]_e \tag{6}$$
$$[C]^e = [N]_e^T [T]^{eT} [c]^e [T]^e [N]_e \quad \{F\}^e = [N]_e^T [T]^{eT} \{f\}^e$$

Using the Hamilton variational principle, The variation of the total potential energy functional (5) , and have the spline discretization dynamic equation of high-rise hybrid building structure system:

$$\mathbf{M}\ddot{\mathbf{X}} + \mathbf{C}\dot{\mathbf{X}} + \mathbf{K}\mathbf{X} = F(t) \tag{8}$$

Improved capacity spectrum method. Using general capacity spectrum method [1, 2] to calculate the target displacement needs to calculate and adjusted demand spectrum according to different equivalent damping values. The convergence performance is poor. Improved capacity spectrum method use elastic-plastic response spectrum as the earthquake demand spectrum. Take superposition calculation for different ductility coefficient of elastic-plastic response spectrum and the structure of power spectrum, and determine the structure of the target displacement. The results have good precision. Principle see paper [3,4].

Examples

As shown in Fig. 1, a steel frame - shear wall hybrid structure, story height 5m, 5 layers. Size of the rectangle steel tube columns is 400mm×400mm, size of beam is 450 mm×200 mm×8 mm×14 mm, thickness of shear wall is 200mm, floor is 100mm concrete slab. Each beam is under vertical load by 10kN/m. Design seismic intensity of 7 degrees, site for the class II, classification of design earthquake1. Analyzed the seismic performance of structures, and compared with the results of finite element analysis software MIDAS/GEN.

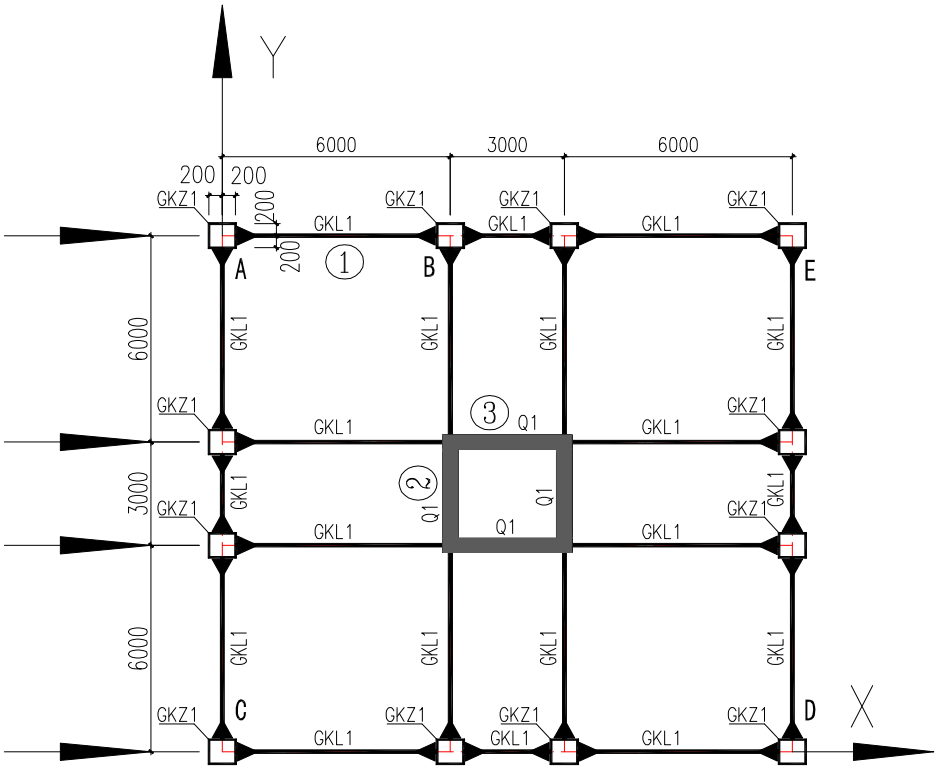

Fig. 1 The layout plane of spatial frame-shear wall structure

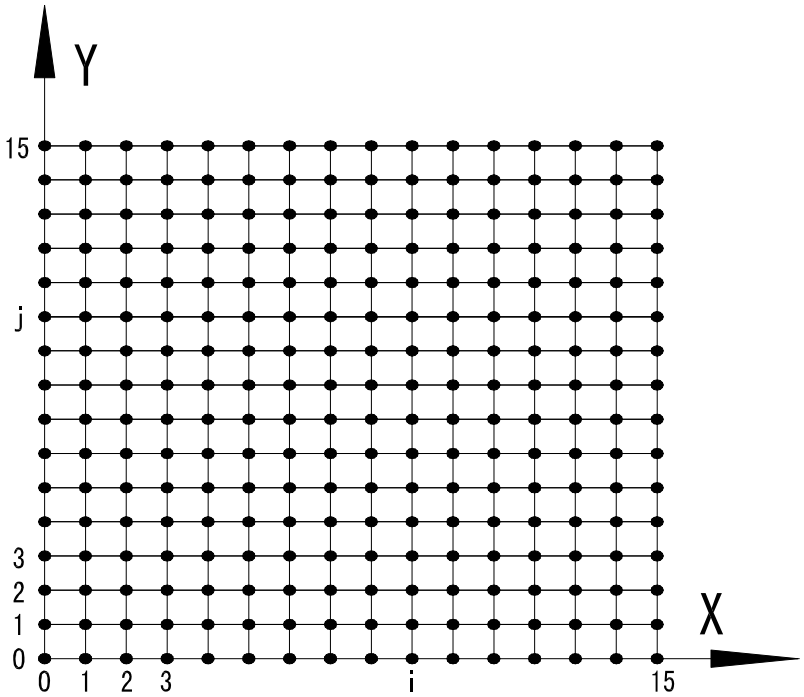

Fig. 2 Spline discrete planar graph

In this paper, discrete the structure by 1m finite element mesh (FIG.2), convergent series R = 5. Based on the first level of vibration mode loading method [5,6], The direction of vibration mode is according to the horizontal force loading direction, using inverted triangle loading mode. Get the displacement and shear force of structure(Table.1).

Table 1 Displacement and shear force of the first vibration mode

Observation Point	The first vibration mode	
	MIDAS	New method
Displacement（mm）	48.21	47.84
shear force（KN）	1663	1785

Conclusion

The improved pushover analysis method introduced in this paper considered the influence of high modes when choose the load mode and target displacement. When structure into elastic-plastic state, number of unknown quantity given no increase, do not need to enlarge stiffness matrix, and the total stiffness matrix form is uncomplicated. Using the overall displacement field function can reflect the whole failure process of the structure better. It can be seen from the results the example that the new method is feasible.

Dynamics Analysis of Manipulator in the Hot Line

Dandan Zhang

College of Mechanical Engineering, Inner Mongolia University for the Nationalities, TongLiao 028000, China

Wangzai8402@163.com

Keywords: high-voltage transmission line, manipulator, dynamics analysis

Abstract. The high voltage transmission lines exposed for a long time are often broken down, thus, The manipulator arm of robot in the hot line was designed, The design is reasonable through kinematical analysis. First, make sure of the connecting rod coordinates and the connecting rod's D-H parameters. Matlab was used to draw 3D model of manipulator. Use functions in the Robotics Toolbox to solve kinematics analysis.

Introduction

Currently the length of EHV line is more than 230,000 kilometers. For the power sector high-voltage transmission lines, towers and its dependencies require regular maintenance, to ensure safe and efficient operation of high voltage transmission lines. Research on inspection robot starts later in our country than abroad.[1] [2] There are mainly Shenyang Institute of Automation, Wuhan University, Inner Mongolia University and other national research units in the field to carry out the research. The high-voltage transmission line maintenance robot which Robotics Institute, Inner Mongolia University for Nationalities developed can solve the problem of high-voltage transmission line maintenance well.

Based on the above, we proposed the studies of high-voltage special operations robot [3]. 500KV six-split transmission lines are usually using six LGJ-240.30 ACSR per phase with tower spanning between 400 ~ 1300m and wire slope <45 °. The robot not only can walk along the EHV transmission lines autonomously with a certain speed, but also intelligently stride across obstacles, which can detect towers, wires, etc by portable detection equipment and sent back the signal to the base station. High-pressure special operations manipulator plays an important role in the patrol line repair process for high-pressure special operations robot [4]. It is focused on the study of dynamic analysis for high-pressure special operations manipulator in the paper.

Analysis on the kinematics modeling of high-voltage transmission line maintenance manipulator

In the program high-pressure special operations manipulator is a more complex multi-drive space mechanism and a multi-variable nonlinear system. The kinematic equations used to describe them is necessarily complex and large. To derive these equations needs heavy workload and it can be error prone. Mathematical models which are created using a computer can be easily to solve these problems. When the constituting of mechanism make some changes, you just need to change some parameters. All the joints are rotational joints. The structural parameters and parameters of joint movement between the lever in manipulator model are shown in Figure 1.

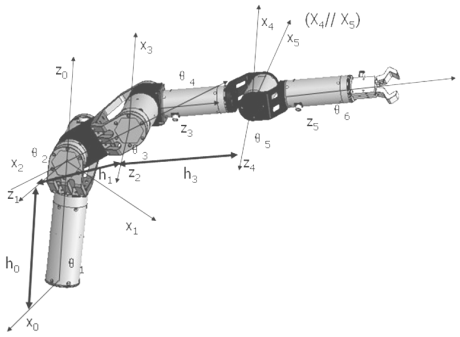

Fig.1 Arm structure mechanical model

1.1 link parameters of maintenance manipulator with D-H transformation

A coordinate system is established. The relationship between the two coordinate systems can be determined by four parameters hi, di, αi, θi from Figure 1.

hi — Along xi axis, the public perpendicular length from zi axis to zi+1 axis, which is called the link length.

αi — Around xi-1 axis, the angle form zi axis to zi+1 axis, which is called the twist angle.

di — Along zi axis，the length form xi-1 axis to xi axis, which is called offset distance or joint displacement.

θi — Around zi-1 axis, the angle from xi-1 axis to xi axis, which is called joint angle or deflection angle.

All the joints of robotic arm are rotated joints which are rotated around the Z axis. The joint angle θi is variable, while hi, di, αi are constant. structure parameters d, h, and the joint variables of the robotic arm are shown in Table

1.2 kinematics equation of high-voltage transmission line maintenance manipulator

Relative position and attitude between the coordinate system of each link is described with the D-H method. The homogeneous transformation to describe a relative relationship with a link to next link is called matrix A. In fact, a matrix A is the homogeneous transformation to describe the relative translational and rotational between coordinates of link. If A1 represents position and attitude from the first link to the base line and A2 represents relative position and the attitude from the second link to the first link. Then the position and posture of the second link in the base system is given by the multiplication of following matrices: $T_2 = A_1 A_2$. Similarly, if A3 represents relative position and the attitude from the third link to the second link, there are $T_3 = A_1 A_2 A_3$. The multiplication of these matrices is known as T matrix. For six degrees of freedom manipulator, there is the following matrix $T_6 = A_1 A_2 A_3 A_4 A_5 A_6$. expresses the kinematic equations between posture and joint variables of the end of link.

1.3 kinematic analysis of manipulator with Robotics Toolbox

Using Matlab Robotics Toolbox modules build a model of three-dimensional manipulator movement. we need to build motion parameters of each joint, and then build the entire manipulator object through a combination of joints [5] [6]. Building a complete manipulator objects means that binding DH parameters, kinematics, joint quality, Coulomb friction, viscous friction and gear ratio, using Matlab Robotic toolbox to build a three-dimensional model of manipulator motion. It needs to use the commands such as link, robot, plot in the Robotic toolbox. For example, we define a base coordinate origin of six degrees of freedom manipulator model, named "Robot-v1".

In practice, the key to control mechanical arm is the inverse position equation, geometric parameters of mechanical arm rod is known, given a specific gesture at the end point, the values of the variables of joint. The inverse kinematics problem can also use the Matlab toolbox in robotics toolbox q = ikine (robot, T) solution. T for the end effector poses matrix, mechanical arm for the 3D model of robot, Q as the variable parameters of each joint values.

The mechanical arm is in a reset state, the definition of each joint variable parameters for the q=[0 0 0 0 0 0], T=fkine (robot, q) positive solution, can get the end effector T at this time.

```
T =
1.0000         0         0    3.0000
     0    0.0000   -1.0000         0
     0    1.0000    0.0000         0
     0         0         0    1.0000
```

The end effector position in space coordinates is (3, 0, 0 for). Then the manipulator inverse solution, Q =ikine (robot, T), each joint parameter q:

q = 0 0 0 0 0 0.

The forward kinematics analysis:

Displacement given by bar and the geometrical parameters of the joints, solving the end effect coordinates relative to the base coordinate position. The forward kinematics problem can use the matlab function T = fkine (robot, q) solution, robot manipulator D-H model. Q is homogeneous transformation matrix pose of the end effecter given, if q is a vector, homogeneous transformation matrix fkine returns the tail end of the connecting rod, and if the q is a matrix will be used as the state vector of a joint, then fkine returns a matrix. For example: set the joint coordinate q = [-pi/4 00 -pi/4 0 0]; it can be used to solve by forward kinematics of fkine. With the trajectory of end joint as an example, Figure 2 is its trajectory.

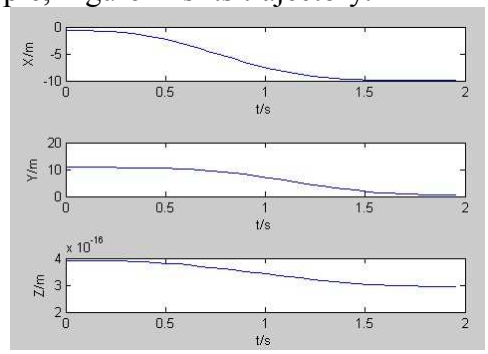

Fig.2 The track of the end joint

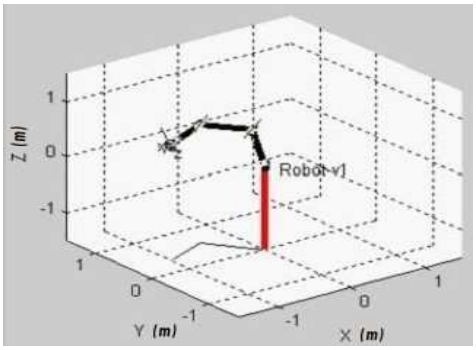

Fig.3 End joint simulation diagram

Inverse kinematics analysis:

Similarly, high pressure special robot manipulator inverse kinematics problem can also use the Matlab toolbox of robotics function in the toolbox q = ikine (robot, T) solution. T given above is 18.1362 1.0607 -0.6113 18.8496 18.9216 -32.2013.

Thus by homogeneous transformation matrix for each joint variable to get the value of . Figure 3 is the end joint simulation diagram.

Through the kinematics of manipulator is analyzed, fully demonstrated the high pressure special robot arm movement can meet the usual free telescopic movement, which verifies the rationality of design parameters of the mechanical arm, and the arm after the three joint motion can make the end joints with different attitude.

2 motion control analysis of maintenance manipulator

2.1 introduce of remote control interface

Combined with Robotics Toolbox in MATLAB plug, Simulink, GUIDE, a visual interface man-machine interface is produced. It mainly consists of three parts: a control operation area, workspace diagram, 3D operating status of manipulator .

Manipulator moves in a trajectory of a straight line. Control operating area can set the sampling interval time. The size of the interval time determines the linear distance of manipulator operation. The current space state parameter of the manipulator can be stored in order to restore the manipulator gesture when it runs next time. The data of each sampling time interval points of each joint can be stored in a document which is self-named to help user call in the controller. Serial operating area can set the parameters of the control interface and controller communication. And

then through downloading computer serial port emulation parameters of the six joints to the controller, it controls manipulator to make corresponding action.

During operation manipulator, by way of video detection, we can artificially predict the position of the target point and input the spatial position where the end of the manipulator will reach in the window, and then it moves to the target position by the manipulator trajectory.

2.2 trajectory control of high-voltage transmission line maintenance manipulator

Using Robotics Toolbox of MATLAB plugin a motion analysis on manipulator is made to build a manipulator motion trajectory control chart.

From Figure 4, we can see that by solving equations of motion with the three manually input position information in1, in2, in3 to the motion controller,, the value of the rotational angle of each joint is obtained. The variables are stored in the six angles which can be used for external manipulator to create a three-dimensional model of manipulator Robot-v1. The value of the joint angle in each of the time interval sample point changes until the desired position, and then the model outputs the manipulator motion trajectory which is drawn in the three-dimensional coordinates. This track is the whole process of the movement from the initial position of manipulator to the target position. The spatial coordinates of the target position point is (0.55, 0,2).

2.3 achievement of motion track

The motion trajectory of maintenance manipulator is always a straight line. The length of straight line is the distance from the expected target point to the current position point, and then the trajectory is divided into aliquots of the time interval sample point which is 0.02s. Each manipulator walking distance is one of aliquot times. Each section of the track must solve the equation of arm reverse movement to calculate the amount of a series of joints. Then the joint is driven by the controller to reach the next target point. Until finishing all of the lines, it reaches a desired point in space. In a given time all the joints and the joint variable parameters under different sampling time points (/ joint angle, unit: radian) are depicted which is shown in Figure 4.

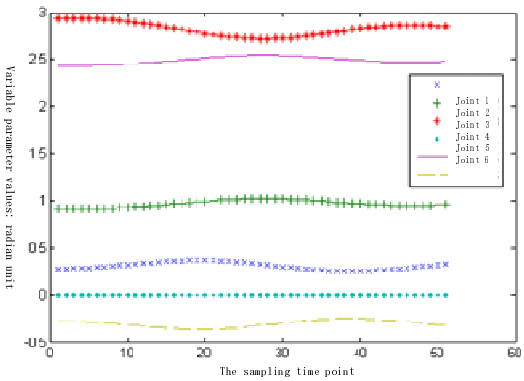

Fig. 4 The joint variables parameter variation chart

3 Conclusions

Denavit-Hartenberg (DH) method is used to establish a kinematic model of the robot manipulator which is used for maintenance of high-voltage transmission lines, and then the manipulator system simulation is achieved by using Robotics Toolbox and GUIDE programming in the MATLAB plugin. Based on analysis of kinematics direct and inverse problems and trajectory planning and the analysis on manipulator motion components and end position of each relationship in the space, an analytical method is provided to control the movement of the robot arm and manipulator kinematics simulation is made to ensure that the robotic arm controllers achieve intended function. Also, through interactive way and program, we make this module software to achieve the motion control of the manipulator track.

Through the analysis of the project shows that the movement of high-pressure special operations robot manipulator joint meet the requirements of the free expansion movement, which further validates the design of geometric parameters of the high-pressure special robot manipulator operations is reasonable.

Keywords: Software, Data stream, Parallel processing

Abstract. According to the signal processing unit in aerospace measurement and control system between the flow of water features, this paper proposes a software suitable for aerospace measurement and control system of driving mechanism. This paper first introduces the basic structure of aerospace measurement and control system software, having studied the static and dynamic data stream driving mechanism on the basis of detailed discusses the design and implementation process of this kind of driving mechanism of data stream. It adopts the method of message control, according to the dynamic data flow driven mechanism, realize the process of the signal processing unit and each signal processing unit between the data flow between the internal thread. Compared the same sort of dynamic data stream driving mechanism, the drive mechanism possesses the advantages of flexibility and easy to implement.

Introduction

With the continuous development of digital signal processing technology and the rapid improvement in general computer performance, the signal processing method in aerospace measurement and control system in has experienced from traditional hardware processing of the analog signal to digital processing based on software radio platform shift, pure software is beginning to change the direction of development. Abroad has been software radar (software radar) and software GPS receiver (GPS software receiver).The software here is different from the software radio, it is out of the programmable DSP and FPGA in software radio platform mainly dedicated hardware platform, the signal after A/D directly with general computer cluster as A platform to build, to complete signal real-time processing software processing way.[1][2] In recent years, computer cluster has been used in the field of large-scale complex data calculation (such as seismic data processing, the forecast calculation).As general, therefore, the continuous improvement of computer performance and network transmission speed, can use computer cluster as a control signal processing hardware platform, software processing way to complete the measurement and control signal of the real-time processing, the realization of software measurement and control system, and make future aerospace measurement and control system by the antenna + general computer cluster signal processing software system structure, software and generalization to measurement and control equipment.

1 System overview

Software is the essence of the aerospace measurement and control system using computer cluster of high-speed data processing ability of measurement and control signal real-time processing, the system structure are shown in figure 1 below. Are connected by a high-speed network and the whole system in high-speed network on the various processing units (including the system master control unit, signal input unit, signal processing unit and terminal processing unit).

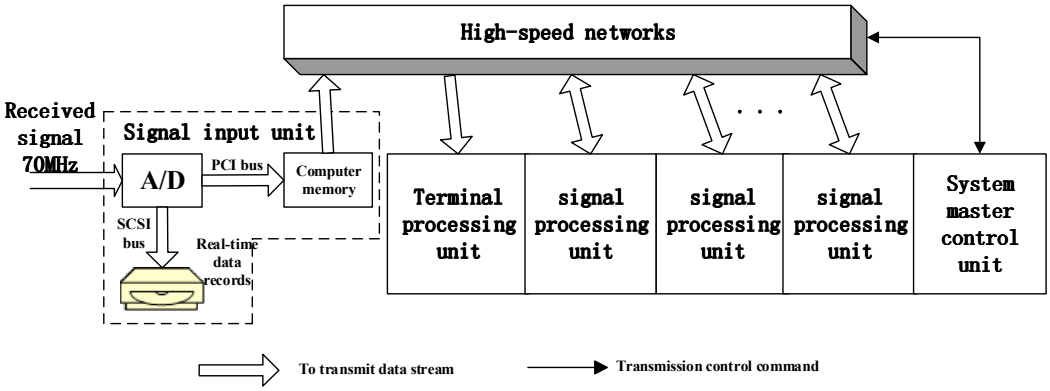

Fig1 System structure

High-speed network used to implement the interconnection between the various processing units. Currently used high-speed network construction of computer cluster has a Gigabit Ethernet, Gigabit Ethernet), high performance parallel interface (HiPPI) and scalable parallel interface (SCI), etc. In terms of network transmission performance, gigabit Ethernet is not the best, but compared with other high-speed network, it has good compatibility, the equipment system the characteristics of easy maintenance and low cost. At present, based on Windows NT operating system and TCP/IP protocol, gigabit Ethernet bandwidth effectively to 85 MB/S (680 MB/S).For USB measurement and control system, transmission code rate is low (maximum 2 MBPS), is BPSK and QPSK modulation way, so the intermediate frequency information is less than 5 MHZ bandwidth. Using bandpass sample solution (sampling frequency 20 installed base, 14 bit quantization) the intermediate frequency signal A/D transformation, get 40 MB/S data flow per second. So using gigabit Ethernet as computer cluster interconnection network can meet the requirements of data transmission. In order to improve the network transmission rate, based on the port must be used together switchboard star network topology structure, make the system work in full duplex mode, send and receive data at the same time.[3] For multiple input multiple output signal processing unit, by installing multiple network card connected to the switch, improve the rate of data exchange.

Each signal processing unit is a high-performance general-purpose computer. In order to improve the system capacity, should choose high frequency, double CPU, large memory capacity of computer as a signal processing nodes. Distribution of each signal processing unit independent of the input and output data buffer, adopted the structure of the table tennis, speaking, reading and writing. Input and output data buffer is divided into two equal, when one piece of data input operation, another piece of data read operations. To receive instruction message with the method of the water treatment, the processor to perform the current instruction at the next higher level to send and receive instruction, and open a thread, distribution computing resources (for input and output buffering), perform new operations, multithreading implementation instructions water treatment.

2 Data flow driven concept

Traditional Von Neumann computer adopts control flow drive mechanism, is through the program counter to determine the program of instruction execution sequence, the program counter sequencing by instructions flowing water. Because is essentially a sequential machine, at the same time, with the method of Shared memory, instructions and data between various correlation and operation control of complicated work may limit the flow of control mode in the development of computational parallelism. Data flow driven mechanism allows any instruction to be driven by data availability. In a data stream driving mode, the data directly in the form of data token passing between the instructions, once all the operands of a operating instructions here, will perform the operation, the operating results have token and then send to wait for these data the operation of the token. According to different tokens for data handling, data stream driving mode can be divided into: static data and dynamic data flows.

Driving mechanism of static data flow is: only when all input data and output the token here token is no output data, the operation can be performed. Token no tags, its main characteristic is data at the given moment when the input or output colleagues appear two or more data token, node will not be able to distinguish between them, which belong to the same data in control must be established in which the token to identify data token from one node to another node. So the static data stream processing efficiency is not high.

Dynamic data flow mechanism is the most important characteristics of the token with an ability to identify the token time successively relationship tag, as long as when the token of the same tag on each input, this operation can be performed. It overcame the shortcoming of static data flow driving mechanism, is currently the most in the world is often driven by the flow of data for data flow machine. However, due to mark the use of token, require specialized hardware to complete additional tags and tags for matching work.

3 Data flow based on message drive mechanism

Software signal processing software in aerospace measurement and control system is based on computer operating system, software system on the current computer operating system is widely adopted message mechanism, by the user to trigger messages, send messages and processing management and control, the realization of the convenient capture and recognition of various kinds of information. Measurement and control signal processing is the feature of the process of water type, a complete process of signal processing is divided into several functional modules, including the output of one or several function modules as the input of one or several function modules. When a module of the input data are in a state of mood, the data processing module began. Therefore, messages can be combination of mechanism and dynamic data flow driven mechanism, using the data in the sending messages as dynamic data flow mechanism tokens, the message in the message queue discharge sequence as to distinguish the token has the identity of the time, so you can according to the dynamic data flow mechanism drive software of aerospace measurement and control system run efficiently.

Processing unit is a software for signal processing in the measurement and control system of the core, in each processing unit contains a separate process, implement a feature in the process of signal processing. Through the process flow of data between drive, realize the measurement and control system of all functions. The data flow between the processing unit to drive the process is as follows:

First step, in the process of signal processing, the output of the signal processing unit at the next higher level after the data preparation, to send the data of the message to the signal processing unit. If the current signal processing unit of input data buffer is available, depending on the received message contained in the data area reads the input data, and send a confirmation message at the next higher level of the signal processing unit, the output data buffer is available at the next higher level. If the current processing unit of the input buffer is unavailable (i.e., cannot write data), at this time will decide whether is the number of data processing threads has reached optimal value (1.2 ~ 1.5 times of cpus). If not reached, then open a new data processing threads, the distribution of input and output data buffer, then according to the received message contained in the data area address complete data read, and at the next higher level node sends a confirmation message. If the current processing unit of data processing threads has reached the maximum value, will receive the message to join to the current processing unit of the message queue, waiting to be processed.

The second step, the current processing unit after completion of the required input data read, if the output data area is available (output data is be read from a lower level), the processing unit for data processing.If the current output data buffer is unavailable (namely cannot write operation data, the main reason is caused by the next level of data processing speed is lower than the speed of data processing), the current processing unit is in the ready state, until the output data buffer is available, the running state of the processor converts the ready state, for data processing.

Third step, the current processing unit will output the result written to the output data buffer, read the data message sent to the next level of processing units, by the lower level circulation in turn perform all operation of the process, data flow between processing units.

Within each signal processing unit consists of a signal processing process, each process includes input control, signal processing and output control three threads. Input control thread receives at the next higher level processing unit to read data sent messages, and will at the next higher level data is read in the input buffer to the current processing unit; Signal processing thread to handle the data in the input buffer, and the data processing results stored in the output buffer, Output control thread data updated in the output buffer, reading messages sent down primary treatment unit. In order to improve the operation efficiency of each signal processing unit, the unit adopts water structure of the data processing method, within each thread given a ping-pong structure of input and output buffering. Through the way of sending a message to achieve input data read, signal processing and data output work in parallel mode.

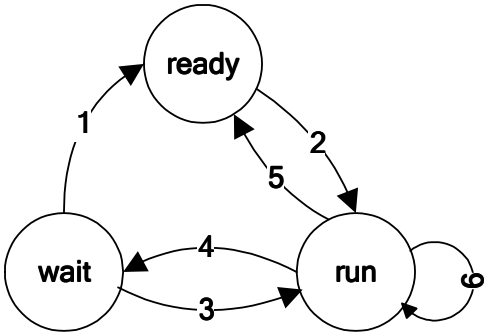

Fig2 Work process state transitions

When input control thread receives the processing unit at the next higher level after reading data from the news, will be done according to the information contained in the data area identification of input data to read. If the output data buffer is unavailable at this time state (that is, the output buffering any a cached data in the table structure was not at the next lower level processing unit finished reading), then this process by "wait" state transition for the "ready" state (1) in figure 2 curve, signal processing threads wait for output control thread sends the message. Output data in the buffer after the data is read by a next level node, the output control thread sends a message to the signal processing thread, in the "ready" state of the process into a state of "run", started the data processing (curve 2 in figure 2).For the process of "waiting" status, if the input the data in the buffer zone is updated, all at the same time in this thread output data buffer data read by the next level processing unit has been finished, the process of converting "waiting" status "running" state (curve 3 in figure 2).When signal processing thread processing has been completed, the input control thread state of data buffer is not available, the process for "waiting" by "running" state transition curve (FIG. 2 (4).If the data has been updated in the input buffer, and the data in the output data buffer is not the primary treatment unit reads (state) is not available, the process by "running" state transition for the "ready" (curve in figure 2. 5).If the input data buffer and output data buffer is available at the same time, the process to continue in a state of "run" (6) curve in figure 2.

Through the message transfer between three threads, control signal processing unit conversion process in working state. Ideally, the signal processing process should be in a state of continuous "run" (6) curve in figure 2.But in the actual cases, due to the different processing units before and after the operation load and processing time delay will be different. So, a signal processing process working condition will be in three different status (i.e., waiting, ready and running) conversion between.

Summary

Proposed in this paper, based on the message control data flow driven mechanism, give full consideration to the characteristics of the current computer operating system platform and stream processing structure of measurement and control signal itself, is suitable for the aerospace measurement and control system software design and implementation, to improve the parallel performance of the system. Compared to the same sort of data flow driving mechanism, the drive mechanism possesses the advantages of flexibility and easy to implement, and by dynamically adjusting the number of data processing threads and processes of work status, make full use of computer resources.

Keywords: SLP algorithm, workshop layout, Witness simulation, logistics optimization

Abstract. In the paper, the connecting rod production line in one workshop is taken as the research object. The workshop layout is designed by SLP algorithm. The specific work includes dividing the operating units, quantifying logistics relations and non-logistics relations, determining the importance of proportion and the integrated relationship of activities that based on the actual situation of the workshop, and then getting the plan finally. The Witness simulation is applied to simulate the theoretical analysis results and imitate the production logistics situation of the factory. Finally, the optimization scheme is determined by the comparison of several schemes in the aspects of logistics and the number of back flow.

Introduction

According to the research, the real time of materials being processed which from raw materials into the plant to the finished products accounts for 5%～10% of the production cycle, however the time of warehouse and transport state accounts for 90%～95% [1]. So production logistics is a key part of corporate logistics. Therefore, only reasonable layout of the production plant, optimized production and logistics systems can enhance the competitiveness of enterprises. The most representative method of the factory layout—System Layout Planning (SLP) which proposed by Richard Muther is applied to the workshop facilities planning [2].Then created a system model with computer simulation technology and simulated the real running. At last, the overall layout of the workshop is improved. So an excellent selection program is presented.

Overview of Layout Methods

The first step of application of SLP method is conducting material flow analysis and activity relationship analysis. Secondly, the space relationship diagram is set up. According to the actual area which each activity needed to decide each area of activities and the actual area instead of relational graph nodes, forming the space relationship diagram. Thirdly, several layout schemes are established based on the actually usable areas, then they are evaluated and preferred. This article set up an improved plant layout design method by combining SLP method with Witness (system simulation software), so that the planning and management personnel can understand the workshop layout scheme intuitively by the Witness. It contributes to the testing, analysis and evaluation of system, so as to achieve the goal of low cost and high efficiency. It can reduce unnecessary materials transport, improve logistics efficiency and cut down logistics cost [3].

Instance

According to the demand of the market, some measures are taken in order to make the construction of workshop meeting the requirements of lean production. For example, solving the exiting problems of the workshop, reducing production cost, maximizing space utilization and optimizing logistics processes. Connecting rod production line is taken as the research object. The workshop mainly

products the models of 265, 240 and 280.The model of 265 of engine connecting bar production line is taken as an example to carry on the analysis.

Division of activity. First of all, we need to divide the activities, the Z represents the set of activity :

Z = （Z1，Z2，…，Zi，…，Zj，…，Zn）

Where n is the number of activity. The logistics quantity of raw materials, accessories and finished products in the manufacturing plant is huge, so the logistics relations and non-logistics relations of the activity all can be evaluated and analyzed by the activity relationship chart. We divide the production line into 24 activities based on the production process of the connecting bar, sort as follows, parts turnover zone, polishing zone , inspection zone, coupling zone, layout block, planer-type milling machine, CNC boring machine, sawing machine, horizontal milling machine, vertical milling machine, CNC rough boring machine, CNC machine center, CNC grinding machine, ABA connecting bar grinding machine, connecting bar grinding machine, horizontal machine center, numerical control vertical milling, radial drill. Draw the initial layout of the workshop and the path of the logistics, as shown in figure 1.

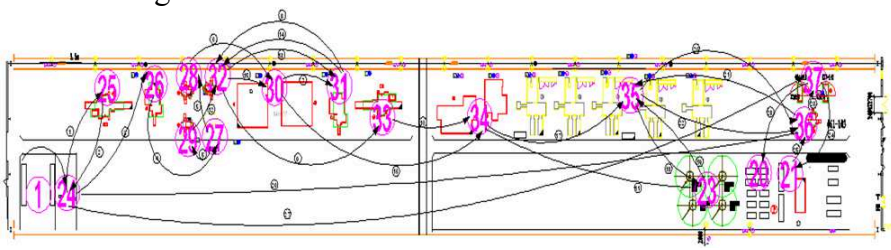

Fig. 1 Workshop initial logistics path graph

Activity's Integrated Relationships Analysis. The placement of the activity Z_j in the workshop is determined by the calculation in the workshop. First, the logistics strength levels of each activity are analyzed. The logistics strength can be converted into five levels which are A, E, I, O and U. Their logistics strength is gradually reduced. These grades are ultra-high, particularly high, higher, general and negligible logistics strength correspondingly. According to the actual situation, the logistics strength level is converted into five levels based on equivalent flow capacity. So the logistics volume in the range of 890-1870 is designated as A level, 210-890 as E, 170~210 as I, 40-170 as O.

As to the analysis of non-logistics relations of activity, 8 main factors is selected which are frequent mergers of materials handing, adapting to requirements of the Tatk Time, operation similarity, common public facilities, the same model of processing equipments, coordination environment of the activity, work safety, urgent degree of service as the main reference factors of the non-logistics. The levels of A,E,I,O,U are determined in the same form of logistics relationship diagram. Then the relationship diagram of activity's non-logistics is set up, as shown in figure 2.

Then the activity's integrated relationships are analyzed. The steps are as follows：

1) It can determine the weighted ratio of relative importance between logistics and non-logistics of the production line as 1:1 in accordance with the production processes of connecting bar and the similar influence between the logistics and other factors.

2) After quantifying the logistics strength grade and the non-logistics close degree level, A is equivalent to4（A=4），E is equivalent to 3，I is equivalent to 2，O is equivalent to 1,U is equivalent to 0,X is equivalent to -1. Then the comprehensive relationship of all the activities that have been quantified is calculated. The total number of activity pair is determined by the formula which is P=N（N-1）/2.In this article, the N is 18, so the P is equivalent to 153(The following lists only list A,E,I,O) .We default the others which are not listed as grade U. So there are 127 pairs of activities of U.

3) Classification of the integrated relationship grade. When merging the correlation table of the logistics and the non-logistics, we should pay attention to the processing of X level because the result of the merging between any level of logistics relationship with the X level of non-logistics relationship should not exceed O level. After the adjustment, we establish the integrated relationship diagram [4], as shown in figure 3.

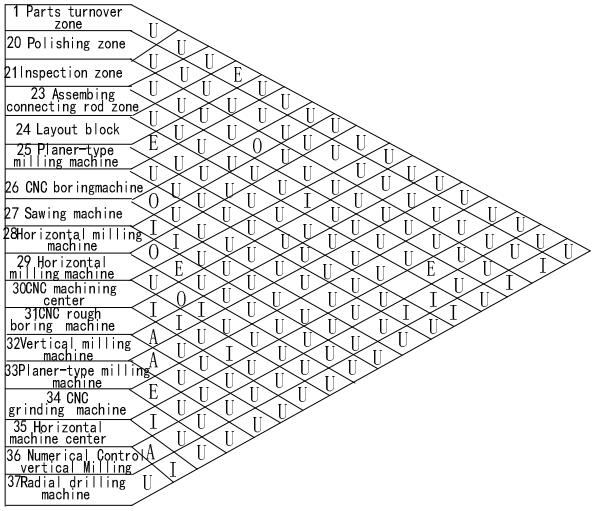

Fig. 2 Non-logistics relationship diagram

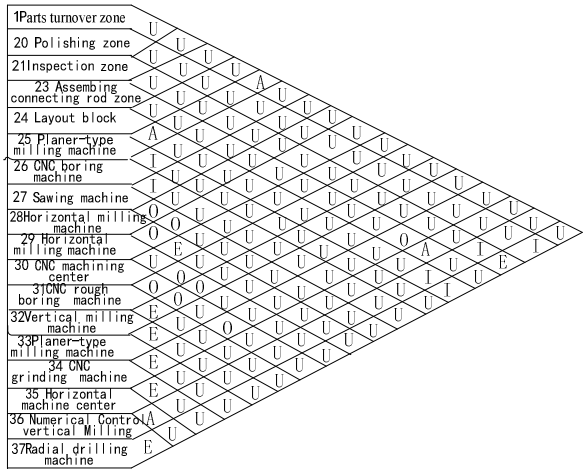

Fig. 3 Integrated relationship diagram

4) The locations of activities are adjusted by area related chart, as shown in figure 4. It can form several layout programs by considering the limitation and effective of all the factors. Then 2-3 feasible schemes can be chose after removing the unrealistic program. At last, the feasible schemes are simulated by the Witness software.

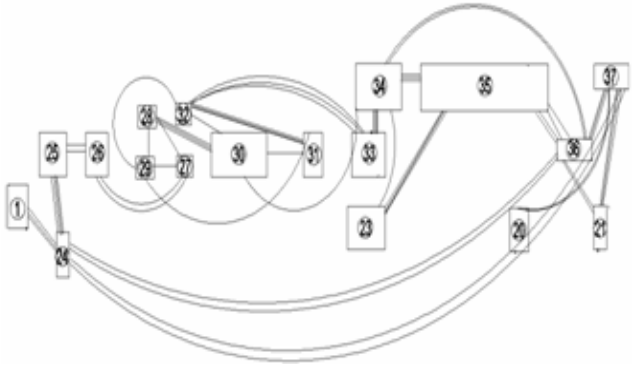

Fig. 4 Area related chart

Simulation

In the paper, the workshop layout is simulated by the software of the Witness. At present, the number of the processes of the model of 265 which is the study object is up to 50 and the entire production line appears that the connecting bar body and cover are placed respectively in different coupling zone. In the workshop, it is easy to emerge a lot of repeated processes and the cross logistics [5].

The first step, the workshop layout is imported into the simulation software of the Witness. Then the entity element's properties of each activity are defined. Through the visual setting of the elements that adjusting the properties of the Text, Icon, Rectangle in the Display box, it can realize flow conditions of the materials between the pairs of the activities in the workshop. So the scheme A and B of the workshop layout simulation modeling are shown in figure 5 and 6. We do some statistics of the size of the workshop logistics by setting the parameters of variable. Specific analysis is shown in table 1.

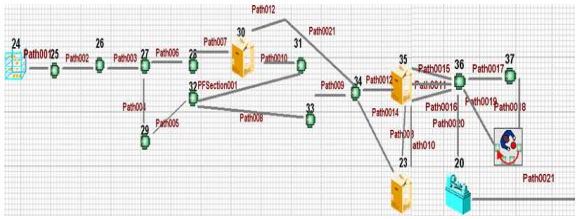

Fig.5 Scheme A

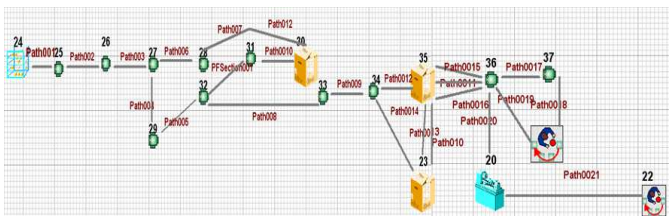

Fig.6 Scheme B

The cost variance that generates from different materials of per unit transportation in different routes is ignored. The cost of material handing is proportional to the distance of handing, that is to say the total cost of material handing is proportional to general distance of handing. The total cost of material handing C is recorded as(1):

$$C = \mathrm{w}\sum_{i=1}^{n} w_i \qquad (1)$$

W—total flow distance

Wi—flow distance between the pair of the i activity

The comparison of the layout of the scheme A, B and the original scheme is shown in table1.

Table 1 Comparison

Layout Scheme	Handing Distance	Flow Distance	Cross Path	Back Flow
Original Scheme	9153.09	4424039	16	7
Scheme A	9311.34	3905807	12	3
Scheme B	8259.55	3908379	12	4

After comparison, the distance, the cost, the number of cross path and backflow of materials handing of scheme B is reduced by 9.76%, 11.66%, 42.86%, 25% compared with original scheme. Above all, scheme B is better than scheme A because the blocking rate of logistics path, the distance, the cost of materials handing and the number of cross path of scheme B get a great improvement while scheme A appeared a phenomenon that the physical distance increases and the total cost reduces. Because the distance of the route which has a large quantity of logistics is reduced .And the distance of the route which has a small quantity of logistics is increased slightly. Then the flow distance of scheme A is less than original scheme. Although the total flow distance is decreased, it is not much more desirable than scheme B. But in manufacturing, 20%～50% of the total operation cost is used by materials handing, so the saving of the cost of materials handing considered preferentially in the layout optimization design. Compared scheme A with scheme B, it can be concluded that B is much better than A.

Summary

In view of the character of bulk production of workshop within the mechanical processing workshop, the system simulation software of Witness combined with the SLP method, it can make up for the shortcomings that SLP method application in the production line is lack of dynamic flexibility and mobility analysis. Through the simulation of the production logistics system with Witness, the layout can be evaluated intuitively and quantitatively. At last, the accuracy and rationality of the workshop layout design can be improved.

Keywords: Battery Manage System, Lithium-ion Battery, Electric Vehicle, Battery.

Abstract. This paper presents an implementation of voltage measuring system in a battery manage system, which is based on micro-controller AT90CAN32 and LTC6802 integrated circuit chips. The design for hardware and software is mentioned in the first, and then an experiment platform is set up for the function test. The test is successful and the result shows that the implementation is valuable and practicable.

Introduction

Many applications, such as plug-in hybrid electric vehicles (PHEV) and fully electric vehicles (EV), have a need for substantially battery pack used as its primary energy storage device [1, 2]. Since one cell voltage is low, a lithium-ion battery usually comprises several cells that are connected in series and/or in parallel to provide the high voltage, current and capacity [3]. It is the weakest cell that determines the performance for the battery that the lowest capacity cell will cause the battery conditions to trip [4]. Therefore, it's essential to have a battery management system (BMS) to monitor the voltages [5, 6].

However, in a BMS of battery stack, cell monitoring and balancing is critical. The voltages of the individual cells will start to drift away from each other throughout the operation of the pack, which will result in a lower efficiency for the operation of the pack. Moreover, when the number of cells grows, its high common mode voltage may be up to several hundreds of volts in modern EV applications, which makes the measurement harder. A possible solution is to use optical isolation between the cells and the measuring unit. Initially, the circuits of measurement for voltage are made from discrete components or special-driving integrated circuits(IC). A multi-winded transformer method is discussed in [7], which requires a transformer for each cell and a set of switches to choose a cell to measure. A differential amplifiers concept is presented in [8], where, high common mode voltage is not a problem since each module has its own ground reference. There're some ICs launched by chip makers, as shown in Table1.

Table 1 List of integrated circuit chips for cell measurement.

Chip maker	Elithion	Linear	AD	TI	Maxim	Atmel

This combination made it difficult to find a suitable IC, but the task finally fell on LTC6802-2. The chip is a complete battery monitoring IC, which includes a 12-bit digital to analogue converter (ADC), a precision voltage reference, and each chip can measure up to 12 series connected battery cells, with a total voltage up to 60V. Each LTC6802-2 has an individually addressable serial interface, which allows up to 16 LTC6802-2 devices interface to one control processor and operate simultaneously [9].

The purpose of this work is to find an efficient, simple and cheap way to keep cells in a battery stack monitored. Since this is one task of the battery management system, the BMS should be mention in this paper. While the field of BMS is quite big, therefore, there are some limits in the thesis.

1. Topology of Voltage Measurement System

The Voltage Measurement System is a component of a BMS, in which a master control chip unit is essential as well as the Voltage Measurement circuit. The master control IC in this paper is AVR AT90CAN32, while LTC®6802 is used as the slave for monitoring the cells in stack. A high-speed serial peripheral interface (SPI) communication links both the terminals together in the topology based on the iCoupler technology, which is shown as Fig.1.

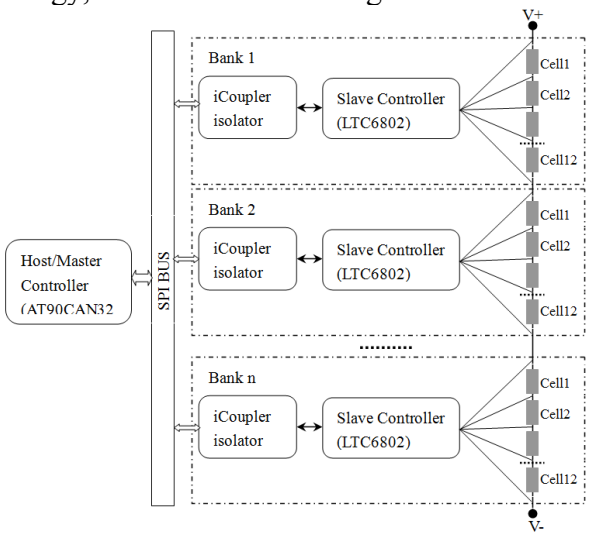

Fig. 1 Topology of voltage measurement system

2. Design of Hardware

The logic of the LTC®6802-2 is generated by its interior circuit, the logic level for the chip are taken out by the Pin VREG and V–. In a Multiple LTC®6802-2 devices application, each of the chips can monitor 12 cells in a bank. To address the proper bank, LTC®6802-2 chip supply its A0, A1, A2, A3 inputs. Although Linear Technology Corporation supplies a daisy-chain topology for applications, there are some drawbacks for this mode [10]. Since all modules have different ground potentials, there some kind of digital isolation between the master and the slave is needed. An Analog Devices has come up with a digital isolator called ADUM1411, which uses the iCoupler® technology. Its block diagram is shown in Fig.2, and Fig.3 is the schematic diagram for measurement circuit.

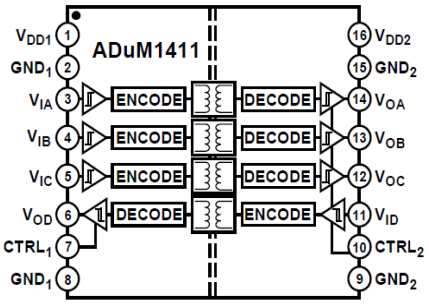

Fig.2 Functional block diagram of ADuM1411

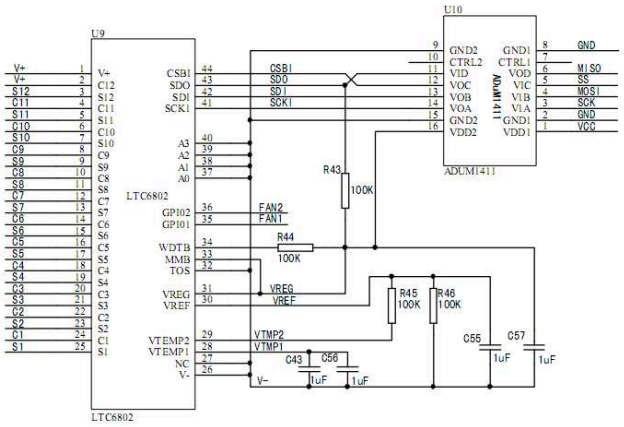

Fig.3 Schematic diagram for measurement circuit

The schematic diagram and Topology are embedded in the BMS printed circuit board (PCB), the layout of the PCB is shown in Fig.4. The voltage measuring circuit is just in the centre of the PCB, where, a car icon is printed, and a LTC®6802-2 is routed. On the right of the board, there are plug-in sockets for linking the cells in the bank, while on the left there are 15 SPI interfaces for other banks. Based on the PCB, an Assembly is finished; the photograph of the BMS is shown in Fig.5.

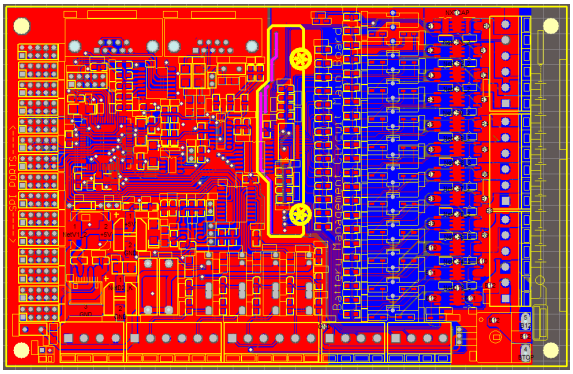

Fig.4 The final version layout of the PCB

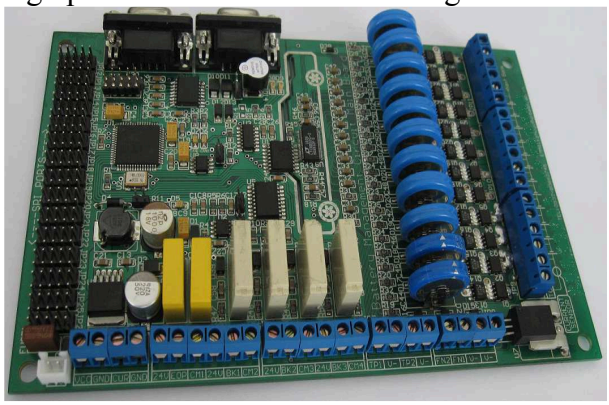

Fig.5 The photograph of the BMS

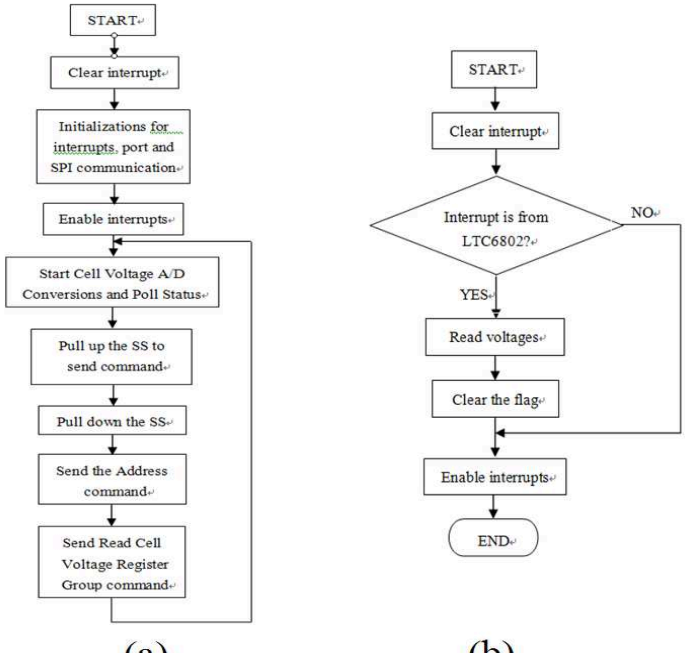
3. Design of Software

The master must accommodate itself to the slave in the communication. Both of them prepare the data to be sent in their respective shift registers, and the Master generates the clock pulses for SCK. Data are shifted from the master to the slave on MOSI, while from the slave to the master on the MISO. After data are packed, the AT90CAN32 will synchronize the LTC6802 by pulling the CSBI down. When exchanging data, the most significant bit (MSB) of the word is transferred first. Where an external oscillator is used as the system clock input, its frequency is $f_{cklio} = 8$ MHZ, so $f_{sck} = f_{cklio}/8 = 1$ MHz. The program flow chart is shown in Fig.6. Fig.6 (a) is the main program chart for the BMS, at first which initializes the BMS, and then enters an endless loop to acquire the voltages from the slave. Fig.6 (b) is the interrupt routine. When the start command reaches LTC6802, it starts an ADC for cell voltage measurement. If the conversion is finished, the slave may feedback data to the master by SPI communication. The arrival of the data in master buffers will trigger the interrupt routine as Fig.6 (b). Thus, an interaction loop mechanism is made, and it goes well in the test platform.



(a) (b)

Fig.6 The program flow chart

4. Test and results

A test platform is set up in this work, which includes a 12-cell-in-stack battery and some voltmeters linked to each of them. The battery voltage measuring system works with the platform. The result is shown in the Table2.

Table 2 Result comparison between the data measured by LTC6802 and detected by voltmeters.

Number for Cell	1	2	3	4	5	6	7	8	9	10	11	12
Measure Data(V)	3.54	3.81	3.97	3.62	3.99	3.56	3.34	3.39	3.94	3.57	3.67	3.33
Detected Data(V)	3.52	3.80	3.94	3.60	3.98	3.56	3.32	3.46	3.91	3.56	3.70	3.32
Absolute Error(V)	0.02	0.01	0.03	0.02	0.01	0	0.02	-0.07	0.03	0.01	-0.03	0.01

5. Conclusions

This paper presents an implementation of a voltage measuring system based on LTC6802 in a BMS. As one of the most important part in the BMS, the demonstration of voltage measuring is carried out on the latest BMS PCB assembly which includes the circuit in this paper. The experimental results indicated that the voltage measurement is achieved with a very accurate circuit as well as it provides up to 12 measurements per module to reduce the cost. Moreover, the topology of the voltage measurement system is stackable and expandable for monitoring large Li-Ion battery packs, with its voltage up to 800 V. Although it is only the first step for a perfect BMS construction, there is some significative work for the further study.

Keywords: horizontal well, low damage fracturing fluid, multistage.

Abstract. Sulige gas field had been developed for a long term, but the yield is hard to keep a high value. How to improve the daily production is a key problem. In the past, we usually fracture horizontal well in single section. In this paper, we talk about horizontal well fracturing in multistage. And meanwhile, introduce some low damage fracturing fluids. Finally, fracturing evaluation shows horizontal well multistage fracturing can improve the yield effectively. This experience can be popularized in similar gas field.

Gas reservoir characteristics

Sulige gas field is located in the Ordos basin in the west of YiShan slope, is a Large lithologic trap gas reservoir develop from Carboniferous - Permian coal measures. The main gas-bearing section is dyas sandstone reservoir of Shihezi formation He8 section and Shanxi formation Shan1 section[1]. Shihezi formation thickness is between 260m and 340m, and better than Shanxi formation in terms of size and connectivity. It is the most favorable reservoir in this area. Shanxi formation stickness is between 70m and 80m, according to the sedimentary sequence, from bottom to top, is Shan1 section and Shan2 section respectively. Shan2 section is the main hydrocarbon source rocks of Sulige gas field He8 section, and Shan1 section is the important auxiliary reservoir of He8 section [2].

The reservoir porosity of He8 section ranges from 4.0% to 13.0%, and mean value is 8.9%; permeability is $(0.03\sim2.0)\times10^{-3}$ μm^2, and mean value is 0.5425×10^{-3} μm^2. The reservoir porosity of Shan1 section ranges from 4.0% to 13.0%, and mean value is 8.5314%; permeability is $(0.04\sim1.0)\times10^{-3}\mu m^2$, and mean value is 0.3566×10^{-3} μm^2. It can be viewed as low porosity low permeability sandstone reservoir. It is hard to develop the gas field based on poor pore structure characteristics. Hence, fracturing is necessary if wish a high yield.

Fracturing technical analysis

Principle. Hydrofracturing is a mining technique in which a liquid (in most cases water) is mixed with sand and chemicals and the resultant mixture injected at high pressure into a wellbore. This creates small fractures in the deep rock formations, typically less than 1mm wide, along which gas, petroleum and brine may migrate to the well. Hydraulic pressure is removed from the well, and then small grains of proppant hold these fractures open once the rock achieves equilibrium [3].

Multistage horizontal well fracturing technology. To Sulige gas field, yield-increasing effect is not obvious after normal fracturing. Therefore, this method is not suitable to Sulige gas field.

Sedimentary system, temperature, pressure and reservoir physical properties of He1 section are similar with Shan1 section. Exploiting reservoirs together are recommended because of thin gas reservoirs and low reserves. Horizontal section length is becoming longer and longer, in order to increase the yield, we should try to increase the number of crack.

Stress characteristics. Sandstone stress is 50.43MPa. Stress difference of sand shale and mudstone is 4.47MPa, and the stress difference of mudstone and sandstone is 6.19MPa. In Sulige gas field the stress difference of He8 up section and down section is 3-10MPa, Physical property difference and heterogeneity are strong. The stress difference of Shan1 section is 6-12MPa, the stress shielding is better.

Matching technology. Depending on reservoir characteristics, to decrease formation damage, we test three kinds of low damage fracturing fluid. They are carboxymethyl, anion and low concentrations of guanidine gum. And we test 300 wells.

Table 1 Compare three kinds of fracturing fluids system with general fracturing fluid system

System types	Surface tension （mN/m）	Sludge content （mg/L）	Gel breaking liquid viscosity （mP.s ）		Ratio of core sample permeability，%	System characteristics
			Lab tests	Theater tests		
General	33.82	510	＜10	7.6	27.06	High thickner concentration, Good theologic property, High residue content
carboxymethyl	31.53	88	＜5	3.3	19.1	Break easily, Flowback easily
anion	28.21	0	＜5	3.2	18.3	No residue, Flowback easily
low concentrations	26.70	290	＜5	3.6	20.0	Low thickner concentration, Gel breaking completely, Flowback easily

Table 1 shows that compare with general fracturing fluid, the advantages of three kinds of fracturing fluids system are low surface tension, low residue content, low ratio of core sample permeability, break easily and flowback easily.

Instance analysis

With the development of horizontal well fracturing technology, the chance of drilling to effective reservoir is becoming higher and higher. During gas testing, the average open-flow capacity improved significantly.

Figure1 shows horizontal well fracturing message from 2010 to 2012. For each year there are three information, they are well number, section number and open-flow capacity from left to right. We can know that the fracturing well number and fracturing section number are becoming more and more, and at the same time open-flow capacity is increasing. These mean multistage fracturing can increase yield effectively.

From table 2 we know that we test 19 wells by low damage fracturing fluids, including 15 wells by low concentration fracturing fluid, average open-flow capacity is 29.3875×104m3/d,4 wells by carboxymethyl fracturing fluid, average open-flow capacity is 17.6011×104m3/d. Compare with general guanidine gum fracturing fluid, Single well output has increased by 4.6 times, Implementation effect is better.

At the same time, we test different kinds of fracturing fluid. The production information is shown in Table 3. From Table 3, we know that the effect of 0.35% carboxymethyl is the best in 3 testing

fracturing fluids. The cumulative production for 100 days is 413.4×104m3. Meanwhile, the cumulative production is 102.4×104m3when using 0.4% carboxymethyl.

Fluid type	V1	V2	V3 (Mpa)	V4 (10^4m^3/d)	V5 (Mpa)	V6 (10^4m^3/d)	V7 (10^4m^3)	V8 (10^4m^3/Mpa)	V9 (10^4m^3/Mpa)
0.50-0.55% guanidine gum	6	6	18.2	1.57	9.6	1.2	113.4	13.2	18.9
0.4% guanidine gum	7	6	21.1	4.78	17.1	3.1	228.6	56.3	38.1
0.35% carboxymethyl	2	5	22.1	4.83	15.8	4.7	413.4	65.9	82.7
0.4% carboxymethyl	2	6.5	19.9	1.55	17.1	0.6	102.4	36.1	15.7

Summary

Three kinds of low damage fracturing fluid can meet multisections of a tight sandstone gas reservoir fracturing needs. Average open-flow capacity can be improved to above 20%. And carboxymethyl and low concentration guanidine gum fracturing fluid have advantage in price and implementation.

Multistage fracturing can raise the yield of gas field, should be extended in other areas and further tests.

In the future, we should try to carry out after fracturing effect evaluation and long-term production of dynamic tracking. To fracturing effect, evaluation method is relatively single. Recommend that increasing crack monitoring, zonal testing, well testing and so on. These works can provide strong support for fracturing effect evaluation.

Numerical Analysis of Heat and Mass Transfer Performance of the Packed-type Parallel Flow Dehumidifier

Zhang Ruihang Wang Ziye Niu runping [a, *]

School of Environment and Energy Engineering, Beijing University of Civil Engineering and Architecture, Beijing 100044, China

[a] niurunping@bucea.edu.cn

Keywords: Heat and mass transfer, dehumidifier; parallel flow

Abstract. TA mathematical model describing heat and mass transfer performance of packed-type parallel flow dehumidifier was set up. The numerical solution of differential equations was derived. Taking the heat and mass transfer coefficients obtained by experiments as the input parameters of the model, the impact of solution inlet parameters on outlet parameter of air was described. The simulation results indicated that the mathematical model could be used to predict the performance of liquid dehumidification. The results showed that the mathematical model can be of great value in the design and improvement of dehumidifier.

Introduction

Solution dehumidifier is a device which the desiccant directly contacts with moistair.It's a device of air dewetting. It's a vital unit of liquid desiccantsystem. Toagreatextent, the whole property of desiccant system depends on desiccant property of dehumidifier. As a result, the research of desiccant property of dehumidifier is particularly important. Wenzhong Gao etc al. [1] devote to improving dehumidifying effect of desiccant solution. They advised adding nano-Cu in the solution to enhancing its heat transfer performance. Zhijia Huang [2] reached a conclusion .That is the bigger padding of specificarea is ,the better dehumidifying effect is in the solutiondesiccant process by using industrial waste heat as heatsource of actified solution. Yaodong Hu, etc al. [3] built model of solution desiccant air-conditioner and applied it into dehumidificationsystem in order to numerical simulation. The deviation of reckoning and experimental results is very small from that model. When liquid desiccant applies into comfortable AC system, author is studying the impact of inlet air and solution parameter on outlet air temperature and humidity. Then draw the influence curve.

The establishment and solving of dehumidifier mathematical model

Establishment of model. In this paper, the parallel adiabatic dehumidifier is adopted, and the stuff we choose to use is metallic padding. The desiccant solution (LiCl) is sprayed from the top of the dehumidifier vertically. On the surface of the filler, an electrolyte film comes into being. There is a saturated air film between air and liquid membrane, and the temperature of it is identified as the same as the one on the solution surface of the saturated air layer. The passing of substances and energy between gas and liquid is through the saturated air layer. Now the mathematical model of the desiccant solution and the forward flow of air are set up, and then we make the following assumptions:

1) Air and solution is an ideal parallel flow, and the flow is stable;

2) There is no heat and moisture exchange between the internal and external environment of the dehumidifier, and the process is adiabatic;

3) The mass transfer resistance is mainly on the side of the air, and the mass transfer resistance on the surface of the solution absorbing the water vapor is neglected;

4) The surface of the stuffing is fully wet, and the interface of heat and mass transfer are the same;

5) The heat and mass transfer only exist in the Z direction ignoring the transfer in the X and Y direction.

According the assumptions below, there is no heat and mass transfer along the length and width direction of the dehumidifier only existing in the direction of height (Z direction). It becomes a one-dimensional heat and mass transfer problem. An infinitesimal body is chosen from the entire dehumidifier to analyze the exchange process between the solution and air. The exchange process of air and liquid complies by the conservation of mass and energy. Analyze an infinitesimal body in the length of dz from figure 2.2 and establish the mathematical model of downstream flow in the following:

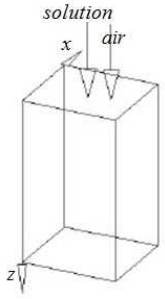

Figure2.1 Physical model of dehumidifier

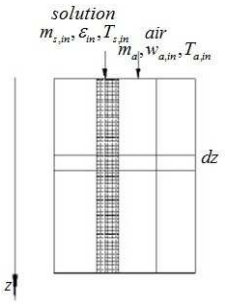

Figure2.2 Schematic plot of downstream

According to conservation of mass, the increment of air humidity equals to the quality change of solution, and that is the mass balanced equation of water vapor in the control volume:

$$m_a \frac{\partial w_a}{\partial z} + \frac{\partial m_{sol}}{\partial z} = 0 \tag{2-1}$$

Where m_a is mass air flow, kg/s ; m_{sol} is mass flow rate of solution, kg/s; w_a is air humidity , g/kg .

According to conservation of energy, the changing of liquid film heat equals to the change of heat-absorption of air, and that is the energy balanced equation in the control volume:

$$\frac{m_{sol}}{DY} dy \cdot \frac{\partial h_{sol}}{\partial z} dz = -\frac{m_a}{DY} dy \cdot \frac{\partial h_a}{\partial z} dz \tag{2-2}$$

Where DZ is the height of padding, mm; DY is the length of padding, mm; h_{sol} is specific enthalpy of solution, kJ/kg ; h_a is specific enthalpy of air, kJ/kg.

Eq. (2-2) can be arranged and simplified:

$$\frac{\partial (h_{sol} \cdot m_{sol})}{\partial z} = -m_a \frac{\partial h_a}{\partial z}$$

Mass transfer equation of air and solution in the control volume:

$$\frac{m_a}{DY} dy \cdot \frac{\partial w_a}{\partial z} dz = -\frac{\alpha_{ad} F_a}{DY \cdot DZ} (w_a - w_{sols}) dydz \tag{2-3}$$

Where F_a is the gas-liquid interfacial area of mass transfer, m^2; α_{ad} is the mass transfer coefficient , kg/m^2s ; w_{sols} is the humidity of solution surface , g/kg.

Make $NTU_{am} = \frac{\alpha_{ad} F_a}{m_a}$, then Eq.(2-3) is simplify:

$$\frac{\partial w_a}{\partial z} = \frac{NTU_{am}}{DZ} (w_a - w_{sols}) \tag{2-4}$$

The change of solution:

$$\frac{\partial m_{sol}}{\partial z} = \frac{m_a NTU_{am}}{DZ} (w_a - w_{sols}) \tag{2-5}$$

Heat transfer equation of air and solution in the control volume:

$$\frac{m_a}{DY} dy \cdot \frac{\partial h_a}{\partial z} dz = -\frac{\alpha_{ac} F_a}{DY \cdot DZ} (t_{sols} - t_a) dydz - \frac{r \alpha_{ad} F_a}{DY \cdot DZ} (w_{sols} - w_a) dydz \tag{2-6}$$

Simplify:

$$\frac{\partial h_a}{\partial z}=-\frac{\alpha_{ac}F_a}{m_a DZ c_{pm}}\left[c_{pm}\left(t_{sols}-t_a\right)+r\left(w_{sols}-w_a\right)c_{pm}\frac{\alpha_{ad}F_a}{m_a DZ}\cdot\frac{m_a DZ}{\alpha_{ac}F_a}\right] \tag{2-7}$$

$$\frac{\partial h_a}{\partial z}=-\frac{NTU_a}{DZ}\left[\left(h_{sols}-h_a\right)+\left(\frac{1}{Le}-1\right)r\left(w_{sols}-w_a\right)\right] \tag{2-8}$$

$$\text{where: } Le=\frac{\alpha_{ac}c_{pm}}{\alpha_{ad}}\ ,\ NTU_a=\frac{\alpha_{ac}F_a}{m_a c_{pm}} \tag{2-9}$$

Heat transfer equation of air and solution:

$$\frac{m_{sol}}{DY}dy\cdot\frac{\partial h_{sol}}{\partial z}dz=-\frac{\alpha_{ac}F_a}{DY\cdot DZ}\left(t_{sols}-t_a\right)dydz-\frac{r\alpha_{ad}F_a}{DY\cdot DZ}\left(w_{sols}-w_a\right)dydz \tag{2-10}$$

Simplify:

$$\frac{\partial h_{sol}}{\partial z}=-\frac{m_a NTU_a}{m_{sol}DZ}\left[\left(h_{sols}-h_a\right)+\left(\frac{1}{Le}-1\right)r\left(w_{sols}-w_a\right)\right] \tag{2-11}$$

Boundary condition:

$$z=0\ ,\ t_a=t_{a,in}\ ,\ h_a=h_{a,in}\ ,\ t_{sol}=t_{sol,in}\ ,\ w_{sols}=w_{sols,in} \tag{2-12}$$

Mass transfer coefficient: adopt the empirical formula [7] in the document.

Formula (2-4),the discrete equation of air humidity can be reached because of using difference equation instead of differential equation:

$$w_a\left(i+1\right)=\frac{NTU_{am}}{DZ}\left(w_a\left(i\right)-w_{sols}\left(i\right)+w_a\left(i\right)\right) \tag{2-13}$$

The change of solution flow rate can be obtained because of the discretization ofdifferential equation (2-5):

$$m_{sol}\left(i+1\right)=m_{sol}\left(i\right)-m_a\left(w_a\left(i+1\right)-w_a\left(i\right)\right) \tag{2-14}$$

The discrete equation of air enthalpy comes from differential equation(2-8):

$$h_a\left(i+1\right)=-\frac{NTU_a}{DZ}\left(h_{sols}\left(i\right)-h_a\left(i\right)\right)+\left(\frac{1}{Le}-1\right)r\left(w_a\left(i\right)-w_{sols}\left(i\right)\right)+h_a\left(i\right) \tag{2-15}$$

The change of solution enthalpy the discretization of differential equation(2-12):

$$h_{sol}\left(i+1\right)=-\frac{m_a NTU_a}{m_{sol}\left(i\right)DZ}\left(h_{sol}\left(i\right)-h_a\left(i\right)+\left(\frac{1}{Le}-1\right)r\left(w_{sols}\left(i\right)-w_a\left(i\right)\right)\right)+h_{sol}\left(i\right) \tag{2-16}$$

According to the equations(2-13)～(2-16)below, easy solved discrete equations are made up.

Solution of Model. The parallel adiabatic dehumidifier is selected, and the form we choose to use is packed tower whose size is 0.4m×0.4m×0.4m,.Metallic perforated &corrugated plate padding is adopted, whose specific surface is 500m^2/m^3.

Table 1 Range of entrance parameter

Inlet parameter Range of LiCl solution			Inlet parameter Range of air		
Concentration	Temperature	Flow rate	Humidity	Temperature	Flow rate
25-35%	25-35˚C	0.3-0.9 kg/s	16-24 g/kg	26-36˚C	0.2-0.9 kg/s

The inlet moist air enthalpy can be received through looking up the enthalpy-humidity diagram by using inlet air temperature and inlet air humidity or from the formula below:

$$h=C_{pg}\cdot t_{sol,in}+(2500+C_{pq}\cdot t)\frac{w}{1000} \tag{2-17}$$

C_{pg} is specific heat at constant pressure of dry air, 1.005kJ/kg·˚C; C_{pq} is specific heat at constant pressure of water vapor, 1.84 kJ/kg·˚C. Mass specific heat of water is 4.19 kJ/kg·˚C

The vapor pressure value of the solution surface can be reached though looking up vapor pressure diagram [6] of LiCl solution by using solution concentration and inlet temperature of solution.

The humidity of solution surface comes from $w = 0.622\dfrac{P_q}{B - P_q}$.

Where B is overall pressure of air; P_q is saturated vapor pressure of wet light bulb temperature.

The air humidity h_{sols} of the solution surface can be reached from (2-17) though looking up specific enthalpy data table of LiCl.

Regarding the parameters below as the initial value, it means that we can receive the value of the first node. The value of the second node can be received by using differential equations(2-14)——(2-16).Each parameter which contains the value of every node in the dehumidifier can be got by operating the MATLAB program written before. As a result, the last value of node is outlet parameter of the dehumidifier.

Analysis and discussion

Our research discusses the impact of inlet parameter on the outlet parameter through making use of numerical simulation method and control variable method. Firstly, choose a standard operating condition.

Table 2 Standard operating condition

Inlet parameter Range of LiCl solution			Inlet parameter Range of air		
Concentration	Temperature	Flow rate	Humidity	Temperature	Flow rate
30%	28˚C	0.6kg/s	20g/kg	34˚C	0.3kg/s

The impact of inlet solution concentration on the outlet parameter of air. When the solution concentration ranges from 25% to 35% and other parameters remain the same, the outlet humidity of air ranges from 14.5g/kg to 12.5g/kg. It means that the humidity removal is increasing because of the rising of concentration of desiccant solution, but the effect is not obvious.

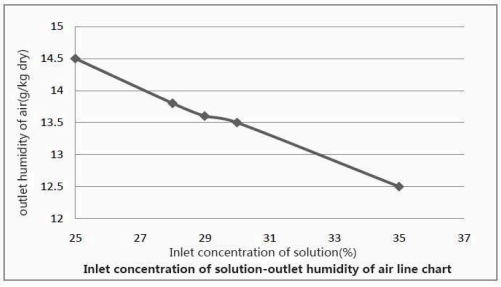

Figure3.1 The impact of inlet solution

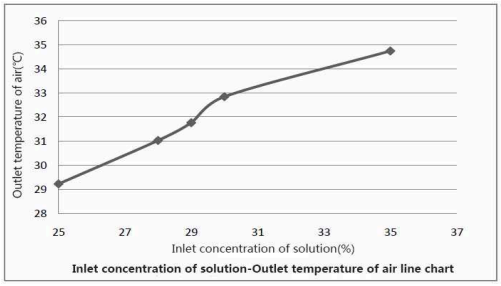

Figure3.2 The impact of solution temperature

It can be seen from figure3.2, the air temperature at the outlet is increasing. Because of the rise of entrance concentration of solution, partial pressure of water vapor on the surface is decreasing. That means the increasing partial pressure of water vapor makes dehumidification improve. So there is more condensed water vapor in the air. Water vapor gives out more latent heat of phase change due to condensing.

The impact of solution temperature on outlet parameter of air. As seen from Figure3.3,air moisture content at the outlet greatly ranges from 11 g/kg to 16g/kg. Air moisture content at the outlet is increasing by the rise of inlet solution temperature. This is due to the increasing solution temperature at the inlet making surface vapor pressure increase. That means partial pressure difference of water vapor is decreasing. It's bad for solution absorbing moisture in the air.

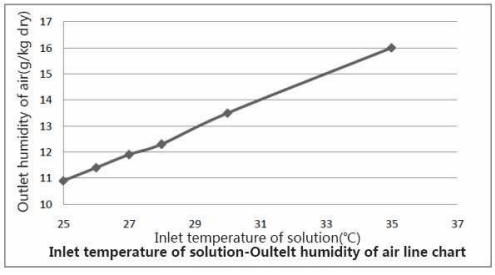

Figure3.3

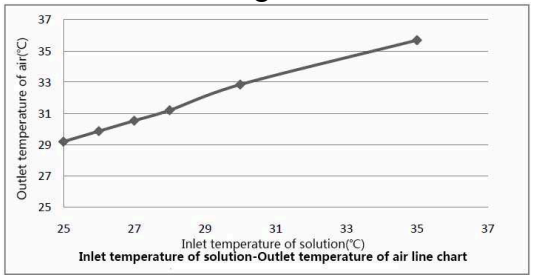

Figure3.4 Air temperature at the outlet rises

Figure3.4 shows that air temperature at the outlet rises from 29℃to 35 ℃. There are the same trend of Figure3.3 and Figure3.4. This is due to the decreasing heat transfer difference between air and solution. And then the outlet air temperature is increasing.

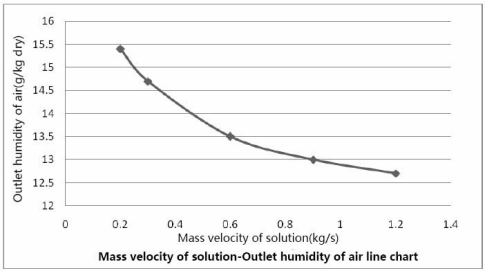

Figure3.5 The temperature of air

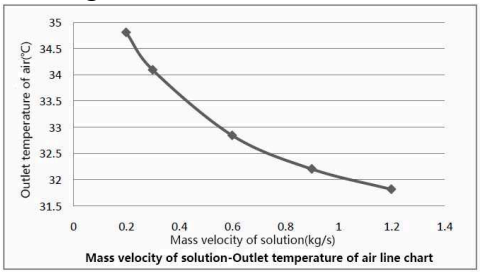

Figure3.6 The temperature of air

The impact of solution mass flow rate on outlet parameter of air. It can be seen from the Figure3.5 that the solution mass flow rate increases 1.0kg/s, and the air moisture content reduces to 12.7g/kg. The air moisture content at the outlet reduces as the solution mass flow rate increases. All of this is because that the increase of solution mass flow rate can promote the mass transfer between solution and air.

As seen from figure 3.6, the temperature of air at the outlet reduces from 34.8℃ to 31.8℃ . This temperature reduces with the increase of solution mass flow rate at the inlet. Because with the increase of solution mass flow rate, heat transfer coefficient increases , which then increases the heat transferring between air and solution.

4 Conclusions

Based on the simulation results, the following conclusions are concluded.

1)Referring to the energy balance and mass balance equation, A mathematical model describing heat and mass transfer performance of packed-type parallel flow dehumidifier was developed.

2)The effects of air flow rate, solution flow rate and inlet parameters of air and solution on the outlet parameters were also investigated.The outlet air moisture content is increasing with inlet air mass velocity, however it is decreasing with increasing of solution mass velocity. The outlet air moisture content is decreasing with increasing of inlet solution concentration.

Abstract. This paper deals with the design and theoretical analysis on a novel vertical lift machine which can vertically lift above 700 kg load up to 3.2 meters above the floor and located the load with high accuracy of position and orientation. Firstly the design model based on the installment demands of line-replaceable units (LRUs) is constructed. Then theoretical analysis including the number of degree of freedom of the lift machine, the inverse kinematic, the control principle, the lift platform pose error and the precise pose control method are conducted in the article. The validity of the design model and the effectiveness of the precise pose control system are confirmed by experiments using a prototype lift machine.

1. Introduction

Our laser facility which use over 2000 large optics of 26 different types to focus up to 48 laser beams on a dime-size target, currently under design and construction, will be the China's largest laser facility when completed [1]. As shown in Fig.1 the optics are held in large optic-mechanical assemblies called line-replaceable units (LRU) supported by a frame assembly unit (FAU) which is suspended 3.2 meters above the floor. The assembled LRUs which weigh up to 700 kilograms, and are about the size of a phone booth have strict specifications with respect to cleanliness, alignment, vibration, and wave-front so that once activated, each beam which must be enclosed in a stringently controlled environment will meet their performance requirements [2].Due to precision alignment requirements of the LRUs, LRUs in canister which mainly supports clean environment itself must be precisely located in 0.1mm position accuracy and 0.1° orientation accuracy relative to the FAU. Some traditional lift equipments such as the scissors lift platform [3], the forklift [4] can meet lifting demands of LRUs installment, but scissors lift platform is always unsteady and the forklift brings a lot errors. This paper deals with the design and theoretical analysis on a novel vertical lift machine which is capable to fulfill the tasks of LRUs installment. The machine primarily adopts 4-*SHS*-1*H* mechanism and a pose error compensation system, Herein, *S* and *H* represent spherical joint and helical joint respectively.

2. Vertical Lift Machine Description

As shown in Fig.1, the vertical lift machine is composed of four primary components: cleanness canister, four jacks leveling mechanism, vertical lift mechanism and electrical control system. Herein the four jacks and lift mechanism are extracted to construct a mechanical transmission model of vertical lift machine as shown in Fig.2. The four jacks leveling mechanism is composed of a fixed base, a moving platform and four identical *SHS* motion chains, which will be used to derive inverse kinematic equations. The 1-*H* mechanism is composed of a fixed base, a moving platform and only one *H* motion chain. The fixed base of leveling mechanism is attached to the earth, but the fixed base of the latter is the moving platform of leveling mechanism. The moving platform of the latter will be

used to lift LRUs as vertical lift machine's end manipulator. Theoretically the LRUs which are aligned with the entrance of FAU can install into the FAU easily when the lift platform and the FAU are paralleled with the same floor. But actually the mission is hardly realized because a lot of error such as fabrication error, measure error and installation error are concurrent. In order to install the LRUs quickly and precisely, the lift platform must be keep level during lifting in case of FAU paralleled with the same floor. The kinematic analysis of the lift machine is conducted in order to realize how to keep the platform level.

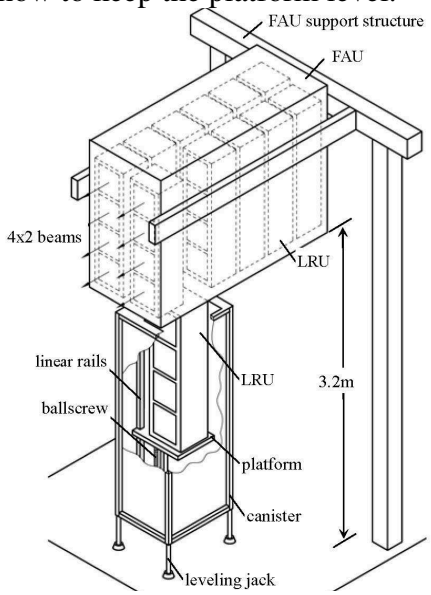

Fig. 1 Arrangement of LRUs in laser facility

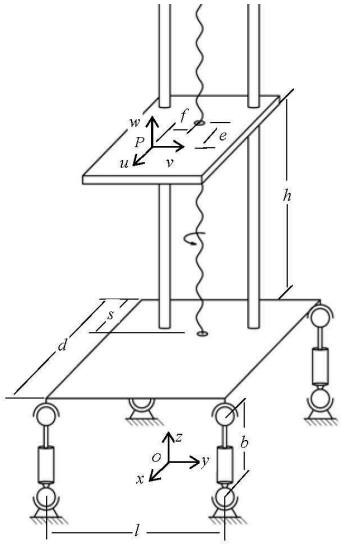

Fig. 2 Mechanical transmission model

The degree of freedom of the 4-*SHS* mechanisms can be solved through the traditional *G-K* formula [5] as follows easily:

$$M = 6(n-g-1)+\sum_{i=1}^{g} f_i + \nu - \varsigma = 6\times(8-9-1)+21-6 = 3$$

Where n is the number of the bar of mechanism, g is the number of kinematic joints of mechanism, f_i is degrees of freedom of i kinematic joints, v is the number of the virtual constraint of mechanism, ζ is the partial freedom of mechanism. It is well known that leveling the platform can be realized by three jacks but one chain of 4-SHS is a redundant motion chain, like door hinges, which is merely designed to reinforce structure rigidity and stability. So the 4-SHS mechanism has three degrees of freedom, which are a rotation about x axis, a rotation about y axis and a translation along z axis.

3. Inverse kinematic analysis

In this section, kinematics of the simplified model is derived and used for the output of precise pose control system. The pose of the load supporting place (LSP) of the lift platform in the machine is represented by the 4x4 matrix operator

$$\begin{bmatrix} {}^{O}S_{\mathrm{i}}{}^{\mathrm{u}} \\ 1 \end{bmatrix} = \begin{bmatrix} {}^{O}_{P}R & {}^{O}P \\ 0 & 1 \end{bmatrix} \begin{bmatrix} {}^{P}S_{\mathrm{i}}{}^{\mathrm{u}} \\ 1 \end{bmatrix} \text{ (i=1}\sim\text{4)} \quad (1)$$

Where ${}^{O}S_{\mathrm{i}}{}^{\mathrm{U}}$ and ${}^{P}S_{\mathrm{i}}{}^{\mathrm{U}}$ are respectively position vector of the upper spherical joint in floor frame $\{O\}$ and platform frame $\{P\}$. ${}^{o}_{P}R$ is the rotation matrix of frame $\{P\}$ related to frame $\{O\}$, and so on. The definition about matrix ${}^{o}_{P}R$ as follows [6]: Start with the frame coincident with a known frame $\{O\}$. Rotate $\{P\}$ first about x-$\{O\}$ by an angle γ, then about y-$\{O\}$ by an angle β, and finally, about z-$\{O\}$ by an angle α. The rotation matrix is

$$ {}^{o}_{p}R = \begin{pmatrix} c\alpha c\beta & c\alpha s\beta s\gamma - s\alpha c\gamma & c\alpha s\beta c\gamma + s\alpha s\gamma \\ s\alpha c\beta & s\alpha s\beta s\gamma + c\alpha c\gamma & s\alpha s\beta c\gamma - c\alpha s\gamma \\ -s\beta & c\beta s\gamma & c\beta c\gamma \end{pmatrix} \tag{2} $$

Where $c\alpha = \cos\alpha$, $s\alpha = \sin\alpha$, α, β, γ are the *X-Y-Z* fixed angles and so on. The inverse displacement problem of this machine can be stated as follows: given the pose (position and orientation) of moving platform and structural parameters, determine four strokes of helical input joints. Suppose the pose of moving platform is given, the rotation matrix as shown in Eq. (2) and ${}^{O}S_{\mathrm{i}}{}^{\mathrm{U}}$ as shown in Eq. (1) are determined When

$$ {}^{O}P = [s+e-d/2,\ f-l/2,\ h+b]^{\mathrm{T}};{}^{o}S_{1}^{U} = [d/2,\ -l/2,\ b]^{\mathrm{T}};{}^{O}o = [0,\ 0,\ 0]^{\mathrm{T}} $$

There are the solutions about ${}^{O}S_{\mathrm{i}}{}^{\mathrm{U}}$ as follows:

$$ \begin{cases} {}^{O}S_{1\mathrm{x}}{}^{\mathrm{U}} = d/2 + h(\sin\alpha\sin\gamma + \cos\alpha\sin\beta\cos\gamma) + (f-l/2)(\sin\alpha\cos\gamma - \cos\alpha\sin\beta\sin\gamma) + (e-d+s)\cos\alpha\cos\beta; \\ {}^{O}S_{1\mathrm{y}}{}^{\mathrm{U}} = (\mathrm{e}-d+s)\sin\alpha\cos\beta - \mathrm{h}(\cos\alpha\sin\gamma - \sin\alpha\sin\beta\cos\gamma) - (f-l/2)(\cos\alpha\cos\gamma + \sin\alpha\sin\beta\sin\gamma) - 1/2; \\ {}^{O}S_{1\mathrm{z}}{}^{\mathrm{U}} = b - (f-l/2)\cos\beta\sin\gamma - (e-d+s)\sin\beta + h\cos\beta\cos\gamma. \end{cases} \tag{3} $$

Suppose α, β and γ equal zero, namely the load platform is absolutely parallel with the floor. According to mechanism theory, ${}^{O}S_{1\mathrm{x}}{}^{\mathrm{U}*}$, ${}^{O}S_{1\mathrm{y}}{}^{\mathrm{U}*}$ and ${}^{O}S_{1\mathrm{x}}{}^{\mathrm{U}*}$ which are coordinate of theoretical level point must be existed in Eq. (2). Thus the stroke of the first helical input joint is obtained as follows:

$$ \Delta H_1 = \sqrt{({}^{O}S_{1\mathrm{x}}{}^{\mathrm{U}} - {}^{O}S_{1\mathrm{x}}{}^{\mathrm{U}*})^2 + ({}^{O}S_{1\mathrm{y}}{}^{\mathrm{U}} - {}^{O}S_{1\mathrm{y}}{}^{\mathrm{U}*})^2 + ({}^{O}S_{1\mathrm{x}}{}^{\mathrm{U}})^2} \tag{4} $$

ΔH_2, ΔH_3 and ΔH_4 are obtained easily in this way.

4. Control Principle

It is well konwn that the cantilever structure which is bearing the load always exists the bench deformation. So these LRUs which are put in the load platform are impossible to be lifted at the required height without any help due to these deformations existed. The offset of pose of the lift platform detected by a level sensor which is located in the platform is then fed to the vertical lift machine's pose error compensation system which drives the four helical legs to determine their respective strokes in Eq. (4). The pose of LRU during Its installment will be real-timely corrected until gaining designed lift position and orientation. The control principle diagram of the lift machine is constructed as shown in Fig.3. β and γ which are the misalignment of the platform from its intended docking orientation are detected by the 2-axis orientation sensor whose precision is superior to fractions of a degree. The mass of LRU is detected by three load sensors, and the lift height is detected by the lift actuator's encoder once the pitch of ball screws and gear speed is given. Of course these parameters have been calibrated with the aid of level instrument, scale, calipers and gravity platform before the lift machine is put to use.

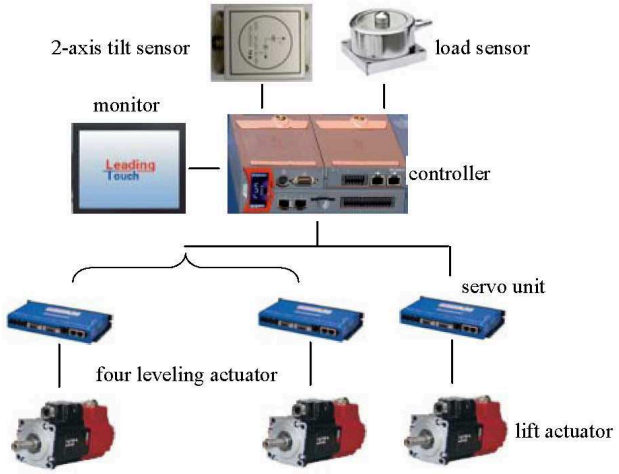

Figure.3 Control principle diagram of lift machine

5. Experiments

In this section, some experiments, such as load capacity, positioning accuracy, orientation accuracy, velocity test were provided to justify validity of the design model and the effectiveness of the precise pose control system. The model parameters of experiment are given in Table 1. The prototype of the vertical lift machine has been fabricated as shown in Fig 4.

Table 1 Parameters of the lift machine

F (Kg)	l (m)	d(m)	b(m)	h(m)	s(m)	e(m)	f(m)
750	1.15	1.1	0.25 ~ 0.58	0.35 ~ 2.80	0.2	0.1	0.1

At last the vertical lift machine obtains a 750Kg LRU positioning accuracy of 0.1 mm and orientation accuracy of 0.1 degree detected by Leica TCA1800 laser ranging equipment (made in Switzerland) at the place where is designed to locate the LRU in FAU. Experimental results state the vertical lift machine meets the demand of the LRUs installment.

(b) LRU lift test

Figure.4 Prototype and test process of the lift machine

6. Conclusion

A novel vertical lift machine which is primarily composed of the 4-SHS-1Hmechanism and pose error compensation system to precisely vertical lift heavy load at large stroke is proposed in this article. At last the linear error less-than 0.1mm and angular error less-than 0.1^{o} are received with the aid of the vertical lift machine. The analysis including the number of degree of freedom of the lift machine, inverse displacement, control principle and the lift platform pose error caused by gravity of load merely during lifting are conducted in the article. The contributions of this study are proposing a kind of vertical lift machines that meets these demands such as heavy load, large stroke, high precision and cleanness. Above all the lift platform pose offset can be compensated real-timely by the kind of vertical lift machine during load-lifting.

Keywords: Flat Wheel, Aspheric Grinding Process, Errors Compensation.

Abstract. The paper mainly studied flat wheel's surface precision, through envelope method, the wheel is used for grinding large aperture axial symmetry aspherical surface. With non-contact measuring method, designed and developed measuring system for wheel in-suit inspection. Aimed at wheel radius errors, proposed the compensation method, so it has certain value to enhance the surface precision.

Introduction

Aspheric method is used for grinding large aperture aspherical surface ,in the process of precision grinding, the diamond plat wheel occured wear, it would influence shape precision. in order to ensure the aspheric surface precision. Lan Shan-chao studied the influence law of the grain size for grinding wheel wear. using the DEFORM, analyzed the wear regularity of single CBN grain. Liu Jia studied the influence law of the processing parameters for corrected surface roughness and grinding force, under the process that diamond roller dressed cup CBN wheel. Got the best corrected parameter[1]~[5].

The paper aimed at plat wheel used for grinding aspherical surface, designed the measuring equipment for wheel in-suit inspection. It could detect the wheel shape error. Build the mathematical model. It was used to analyze the wheel's surface precision. measured the wheel radial error and carried out the compensation grinding test for 330~330mm square axial symmetry aspheric surface.

Envelope grinding theory for aspheric surface

When the generation line rotates about its rotational axis, the surface of revolution will form. This is structural feature of the axial symmetry aspheric surface. The aspheric surface meridional transversal is the rotational generation, the mathematical expression of curvilinear equation is:

$$Z(x)=\frac{cx^2}{1+\sqrt{1-c^2(k+1)x^2}}+dx^4+fx^6+gx^8+..... \quad (1)$$

c---------- surface vertex curvature, $c=1/R_0$;

R_0----------surface vertex curvature radius;

k----------quadric surface eccentricity function;

d,f,g--------higher term coefficientof the equation;

z---------- rotational axis of the axial symmetry aspheric surface.

When k<-1,the shape is hyperbola; when k=-1,the shape is ellipse;when -1<k<0,the shape is circle; when k>0,the shape is oblate ellipsoid. When the rotational generation rotates about Z axis, secondary rotational surface will take shape.

The envelope grinding theory for aspheric surface was shown in the Fig.1.In grinding processing, along the aspheric surface optical element meridian,the X,Y,C axis achieved interpolation motion. It

ensured that grinding point was always tangent to the aspheric optical elementsurface.Through the work piece rotary motion,wheel feed movement and rotational motion of wheel spindle turntable, the aspheric optical could be grinded out. According to the envelope grinding theory, Each axis equations of motion are:

$$X = x_i - R_w \times Sin(\arctan(f'(x_i)))$$
$$Z = f(x_i) + R_w \times Cos(\arctan(f'(x_i))) \quad (2)$$
$$C = \arctan(f'(x_i))$$

X, Z, C ——control center coordinatesof the machine tool;

x_i ——interpolate Point x position of the axial symmetry aspheric surface generation;

$f(x_i)$ ——the axial symmetry aspheric surface generation function;

R_w ——plat wheel radius;

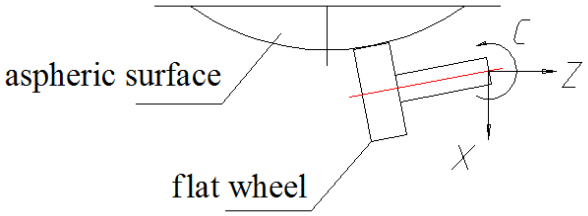

Fig.1. The theory of the plat wheel grinding the aspheric surface

Design of the wheel measuring system

The diamond particles form diamond wheel by cementation. So the wheel is a kind of porous object. According to different shapes, the diamond wheel includes plat wheel ,arc wheel and Spherical wheel. The plat wheel is often used to grind convex aspheric surface, as shown in the Fig.2;But the wear caused by long-term use will change the surface shape accuracy, then influence grinding performance and profile accuracy, therefore, before grinding the aspheric surface, must measure the wheel profile error, choose appropriate wheel radius, and achieve surface error compensation during grinding.

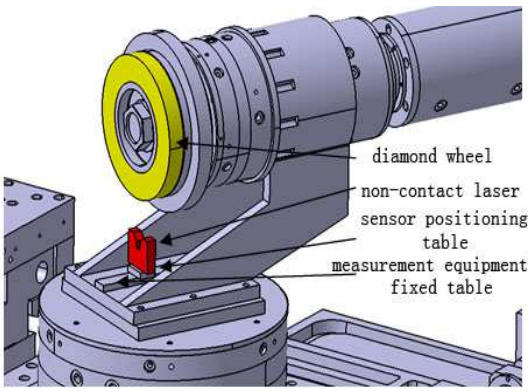

Fig.2. Measuring system for flat wheel in-suit inspection

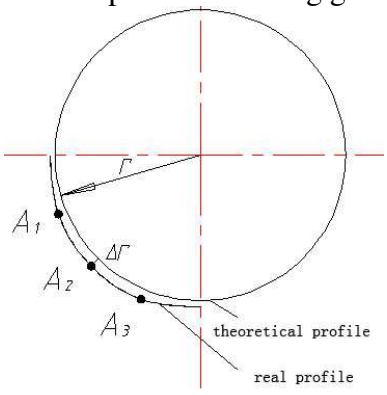

Fig.3. Plat wheel measuring point

In this paper,designed and developed measuring system for wheel profile in-suit inspection,the system included non-contact laser displacement measurement sensor,sensor positioning table,measurement equipment fixed table and measurement software.The measurement range was ±1mm,beam diameter was 1mm×20μm,resolution ratio was 0.02μm,measurement accuracy was ±0.1μm,and sampling period is 110μs.As shown in the figure 3,when measuring,the non-contact laser pointed at width midpoint of the plat wheel,when the wheel rotated a circle,the shape precision of circular cross section could be measured,then figured out the wheel radius, profile accuracy and radial error.

Wheel shape error compensation method

As shown in the figure 3, the wheel surface existed non-collinear three points:A_1 (x_1, y_1), A_2 (x_2, y_2), A_3 (x_3, y_3).the outer circle equation was:

$$x^2 + y^2 + Dx + Ey + F = 0 \tag{3}$$

plugged A_1 , A_2 , A_3 into equation(3):

$$\begin{cases} x_1 D + y_1 E + F = -(x_1^{\,2} + y_1^{\,2}) \\ x_2 D + y_2 E + F = -(x_2^{\,2} + y_2^{\,2}) \\ x_3 D + y_3 E + F = -(x_3^{\,2} + y_3^{\,2}) \end{cases} \tag{4}$$

according to Cramer's rule:

$$D = \frac{\begin{vmatrix} -(x_1^{\,2}+y_1^{\,2}) & y_1 & 1 \\ -(x_2^{\,2}+y_2^{\,2}) & y_2 & 1 \\ -(x_3^{\,2}+y_3^{\,2}) & y_3 & 1 \end{vmatrix}}{\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}} = \frac{\begin{vmatrix} -(x_1^{\,2}+y_1^{\,2}) & y_1 & 1 \\ (x_1^{\,2}+y_1^{\,2})-(x_2^{\,2}+y_2^{\,2}) & y_2-y_1 & 0 \\ (x_1^{\,2}+y_1^{\,2})-(x_3^{\,2}+y_3^{\,2}) & y_3-y_1 & 0 \end{vmatrix}}{\begin{vmatrix} x_1 & y_1 & 1 \\ x_2-x_1 & y_2-y_1 & 0 \\ x_3-x_1 & y_3-y_1 & 0 \end{vmatrix}}$$

$$E = \frac{\begin{vmatrix} x_1 & -(x_1^{\,2}+y_1^{\,2}) & 1 \\ x_2 & -(x_2^{\,2}+y_2^{\,2}) & 1 \\ x_3 & -(x_3^{\,2}+y_3^{\,2}) & 1 \end{vmatrix}}{\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}} = \frac{\begin{vmatrix} x_1 & -(x_1^{\,2}+y_1^{\,2}) & 1 \\ x_2-x_1 & (x_1^{\,2}+y_1^{\,2})-(x_2^{\,2}+y_2^{\,2}) & 0 \\ x_3-x_1 & (x_1^{\,2}+y_1^{\,2})-(x_3^{\,2}+y_3^{\,2}) & 0 \end{vmatrix}}{\begin{vmatrix} x_1 & y_1 & 1 \\ x_2-x_1 & y_2-y_1 & 0 \\ x_3-x_1 & y_3-y_1 & 0 \end{vmatrix}}$$

plugged D, E into original equation,got the $O(x_0, y_0)$ expression：

$$\begin{aligned} x_0 &= -\frac{D}{2} = -\frac{1}{2}\frac{(y_3-y_1)(x_1^{\,2}+y_1^{\,2}-x_2^{\,2}-y_2^{\,2})-(y_2-y_1)(x_1^{\,2}+y_1^{\,2}-x_3^{\,2}-y_3^{\,2})}{(x_2-x_1)(y_3-y_1)-(x_3-x_1)(y_2-y_1)} \\ y_0 &= -\frac{E}{2} = -\frac{1}{2}\cdot\frac{(x_2-x_1)(x_1^{\,2}+y_1^{\,2}-x_3^{\,2}-y_3^{\,2})-(x_3-x_1)(x_1^{\,2}+y_1^{\,2}-x_2^{\,2}-y_2^{\,2})}{(x_2-x_1)(y_3-y_1)-(x_3-x_1)(y_2-y_1)} \end{aligned} \tag{5}$$

Actual measurement wheel radial error was:

$$\Delta r = r - R_w = \sqrt{(x_1-x_0)^2+(y_1-y_0)^2} - R_w \tag{6}$$

Considering the actual measurement wheel radial error,the actual grinding control equation was:

$$\begin{aligned} X &= x_i - (R_w + \Delta r)\times Sin\left(\arctan(f'(x_i))\right) \\ Z &= f(x_i) + (R_w + \Delta r)\times Cos\left(\arctan(f'(x_i))\right) \\ C &= \arctan(f'(x_i)) \end{aligned} \tag{7}$$

Compensation grinding test

The aspheric surface accurate grinding tool adopted linear interpolation method and could achieve the grinding test.The wheel revolving speed was 1100rpm,workpiece rotational speed was 81rpm,the grinding feed was 0.5μm, the feed speed was 10mm/min.The tool could grind 330~330mm square axial symmetry aspheric surface, the inductance type micrometer with 0.01μm resolution could

measure the first grinding aspheric surface and measured surface error was 12μm,the result was shown in figure 4.

After measuring ,should compensated the wheel radius.When compensation grind completed with the same parameter,the measurement aspheric surfaceerror PV was less than 3μm,the result was shown in figure 5.

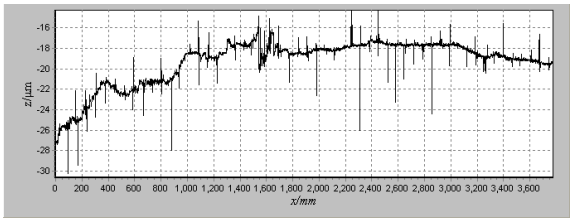

Fig.4. The initial grinding diagonal error

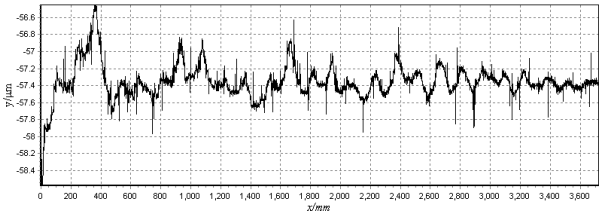

Fig.5. The compensation grinding diagonal error

Conclusion

The paper mainly studied flat wheel's wear problem,through envelope method,the wheel is used for grinding large aperture axial symmetry aspherical surface.With non-contact measuring method,designed and developed measuring system for wheel in-suit inspection. Proposed the wheel radius errors compensation method and carried out the compensation grinding test for 330~330mm square axial symmetry aspheric surface.It was observed that developed wheel measurement device could achieve the wheel on-machine measurement request,its measurement accuracy was ±0.1μm and speed was very fast.The compensation grinding test showed that the wheel radial compensation method could satisfy the aspheric surface grinding request,the accuracy was improved by 9μm,So it has certain value to grind the aspheric surface.

Abstract. In this paper, functions of intelligent fault monitoring system of hydraulic excavator are analyzed. Architecture of the fault monitoring system is presented. Key technologies of the monitoring system are discussed detailed. Key parts of the fault monitoring system such as inspection controller, travel controller and programmable monitor, remote monitoring system is developed. As a result, the intelligent monitoring system is of great useful for monitoring the faults of hydraulic excavator.

Introduction

Fault is one of the main factures which affect the hydraulic excavators' working efficiency. Two methods can be used to decrease the faults. One is improving the reliability the machine's design and manufacturing process. The other is to detect and eliminate the fault in time. Due to the severe working condition, faults of hydraulic excavator cannot be eliminated completely through the design and manufacturing process. Using the fault monitoring system, fault of the construction machines can be detected and eliminated rapidly. In the monitoring system, faults are detected by the sensors set on the fault parts. Fault monitoring system is seen as one of the key parts of modern construction machines by the construction machine manufactures such as Caterpillar, Kamatsu, Volvo, Hitachi , Xugong, Shantui[1-4], etc. Caterpillar's monitoring system named as EMS and Advisor. Kamatsu's monitoring system is KOMTRAX. Both of the monitoring systems of caterpillar and Kamatsu have the following functions[1,2]: monitoring the temperature of motor cooling water, oil temperature of hydraulic system, transmission system, oil pressure, fuel level, air piper temperature, cooling water flux, electric system's working condition, etc. The application of the monitoring system greatly improved the constructions' quality.

Obvious progress have made in the area of monitoring systems' research and development, however, most of domestic hydraulic excavator manufacturer have not developed a useful fault monitoring system for hydraulic excavators. Therefore, this paper proposed a hydraulic excavator's fault monitoring system. The system can meet the requirements of fault monitoring and intelligent diagnostics of modern hydraulic excavator.

Architecture of the Fault Monitoring System

To execute the monitoring function, the monitoring system is designed to be composed of sensors, system controller, motor electrical control unit, traveling controller, detection controller, GPS terminal device, data base server and user interface, etc. System controller is used to receive and display the inspection data. The controller can be divided into programmable controller, programmable monitor and CAN bus. Traveling controller is used to control the machine's movement. Functions of the detection controller are dealing with detection data. Sensors are used to monitoring the parts' status and collecting state data. GPS terminal device is used to send the monitoring data to the remote monitoring system (center) and receive the orders from the monitoring system. The remote monitoring system is applied to remote monitoring the machining working status and displays the monitoring data on its screen. When necessary, the monitoring center can send out instructions to control the hydraulic excavator. Construction of the system is shown in Fig.1.

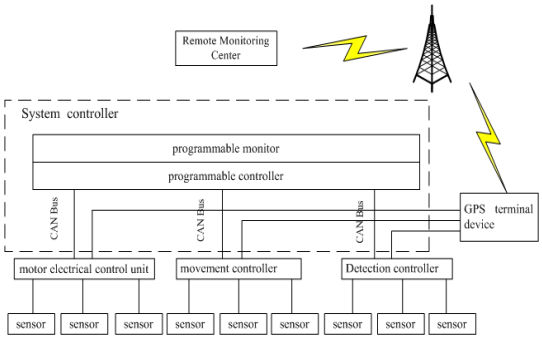

Figure 1. Construction of the Fault Monitoring System

Key parts of the Fault Monitoring System

1. Detection controller

Detection controller is connected with air cleaner sensor, working oil cleaner sensor, traveling oil cleaner sensor, fuel level sensor, hydraulic oil temperature sensor, travel brake solenoid valve, start the system battery relay, start battery relay, safety battery relay, and start motor. The controller real time detects the sensors and analysis the collected data. Using the CAN bus, the analyzed data is transferred to the monitor. The data is further analyzed by the monitor. If the abnormal signal is found, the fault message will be informed to the hydraulic excavator diver through the words displayed on the monitor's screen. The displayed message contains air cleaner clogging, movement oil cleaner clogging, movement brake magnetic valve fault, hydraulic oil temperature, etc.

2. Traveling controller

Traveling controller is connected with traveling systems handle, solenoid valves, travel motor and motor speed sensors. Using the data transferred from the sensors, the controller can make the judgments of the handle potentiometer's working status, CAN bus's communication status, solenoid valve's working status, travel motor's working status, etc. The judgments accompanied with handle resistance value and motor speed values are transferred to the monitor. The received signals classified and processed by the monitor, and then informed to the driver.

3. Programmable monitor

The programmable monitor is composed of ARM series CPU, 2M memories FLASH, real-time clock chip, memories for the parameters storage, monitor control chip, LED light control chip, etc. The whole system runs under the control of the ARM CPU. The monitor communicate with engine and controllers through CAN bus. Monitor received the monitoring information through the CAN bus, judge and displays the analogs (such as engine cooling water temperature, oil pressure, fuel quantity, and so on), switch information and alarm messages.

4. Remote monitoring system

Remote monitoring system is composed of GPS device, computer hardware and software.GPS device contains GPS module, communication module, control module. Main function of the control module is processing the received information. GPS module is used to positioning the hydraulic excavator. Communication module is used to send and receive the wireless signal. A user interface is developed to display the monitoring information of hydraulic excavators. Using the interface, information of the hydraulic excavator (Fig.2) working status (Fig.3), and monitoring parameters (Fig.4) can be displayed.

Keywords: Machine Tool, Feed Drive Vibration, Trajectory Profiles

Abstract. The motion commands to feed drives constitute a major source for excitation of the vibrations. In this paper the vibration of feed drive caused by the motion commands is simulated by using a mathematic method. The mechanical transmission system is modeled as a dual inertia system. Three typical trajectories are used to analyze the effect of motion profiles on feed drive vibration by using a simulation model of feed drive controller.

Introduction

The motion commands to feed drives constitute a major source for excitation of the vibrations [1]. In order to push the speed and accuracy boundaries of present systems further, current research focus on the vibration reduction and avoidance of the feed drives. Additional damping modules or structures are integrated in the control loops to achieve this goal, such as semi-active damping system and set point filtering etc. Active damping system reacts only when a vibration is present and set point filtering can lead to path deformation [2, 3, 4]. Another way to solve this problem is generate a smoother trajectory. For this purpose, numbers of trajectory algorithms are found out and the frequency contents of the trajectory orders are discussed and compared [5, 6]. The vibration caused by the trajectory is difficult to analyze on hardware because of the coupling factor of various excitation sources.

In this paper the vibration of feed drive caused by the motion commands is simulated by using a mathematic method. The mechanical transmission system is modeled as a dual inertia system. Three typical trajectories are used to analyze the effect of motion profiles on feed drive vibration by using a simulation model of feed drive controller.

Structural dynamic model of feed drive

The typical structure of ball screw drive system consists of servo-motor, lead screw coupling, ball screw with nut and table, as shown in Fig. 1. Ball screw drives exhibit torsional flexibilities at the motor shaft-screw coupling, screw itself, and nut. Currently the structural flexibility of the machine tool reflected to the drive is not explicitly considered in rigid body based controllers. Rigid body transfer function can't describe the vibrations of the ball screw feed drive. Thus the flexible body model of the feed drive is needed to illustrate the vibrations of the ball screw feed drive.

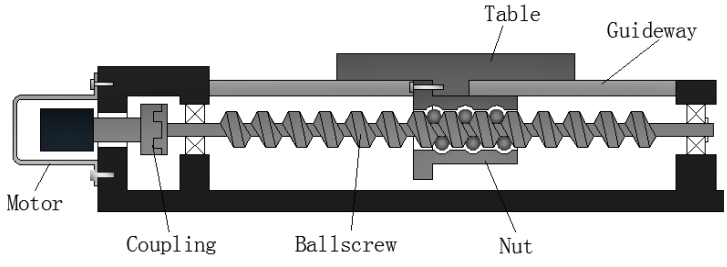

Fig. 1 Typical structure of ball screw drive system

A simple structural dynamic model of the ball screw drive system can be approximated by the reflected inertias at the motor (JM) and lead screw (JL) connected by a torsional spring (k) and damping (c) elements as shown in Fig. 2. The relative vibration of the dual inertia system can be denoted as $\theta_M - \theta_L$.

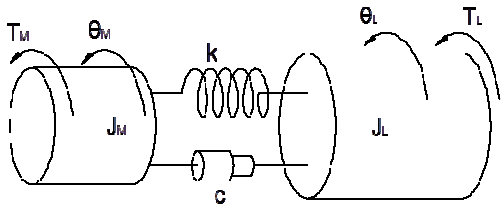

Fig. 2 Dual inertia system model of feed drive

According to D' Alember's principle we have:

$$\left.\begin{aligned} J_M\ddot{\theta}_M + c(\dot{\theta}_M - \dot{\theta}_L) + k(\theta_M - \theta_L) = T_M \\ J_L\ddot{\theta}_L + c(\dot{\theta}_L - \dot{\theta}_M) + k(\theta_L - \theta_M) = T_L \end{aligned}\right\} \tag{1}$$

Where θ_M, T_M are the angle motion and torque of the motor shaft. θ_L and T_L are the angle motion and torque of the lead screw. The structural dynamics of the ball-screw system can be expressed by:

$$\left(s^2\begin{bmatrix} J_M & 0 \\ 0 & J_L \end{bmatrix} + s\begin{bmatrix} c & -c \\ -c & c \end{bmatrix} + \begin{bmatrix} k & -k \\ -k & k \end{bmatrix}\right)\begin{Bmatrix} \theta_M \\ \theta_L \end{Bmatrix} = \begin{Bmatrix} T_M \\ T_L \end{Bmatrix} \tag{2}$$

The transfer function of the system can be leaded as:

$$[G(s)] = \frac{\begin{bmatrix} J_L s^2 + cs + k & cs + k \\ cs + k & J_M s^2 + cs + k \end{bmatrix}}{s^2\left[J_M J_L s^2 + c(J_M + J_L)s + k\left(J_M + J_L\right)\right]} \tag{3}$$

The system has the torsional natural frequency:

$$w_n = \sqrt{\frac{k(J_M + J_L)}{J_M J_L}} \tag{4}$$

The block diagram of the dual inertia system is as Fig. 3:

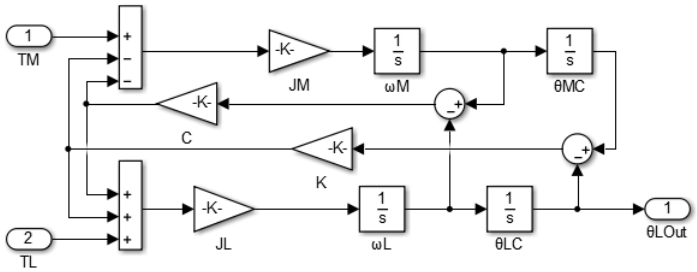

Fig. 3 Block diagram of transmission mechanisms

Dual inertia system based simulation of the feed drive system

Trajectory generation. The present CNC systems use linear acceleration motion profiles, trapezoidal acceleration motion profiles and sine-squared acceleration motion profiles. The acceleration functions are as function (5), (6), (7). Where $A_{L(t)}$, $A_{T(t)}$ and $A_{S(t)}$ are the acceleration profiles of linear acceleration profiles, trapezoidal acceleration profiles and sine-squared acceleration profiles. V_m, A_m and J_m are the maximum velocity, the maximum acceleration and the maximum jerk of the trajectory profiles.

$$A_{L(t)}=\begin{cases} A_m,(t\in[0,t_1)) \\ 0,(t\in[t_1,t_2)) \\ -A_m,(t\in[t_2,t_3)) \end{cases} \tag{5}$$

$$A_{T(t)}=\begin{cases} J_m t,(t\in[0,t_1)) \\ A_m,(t\in[t_1,t_2)) \\ -J_m(t-t_2),(t\in[t_2,t_3)) \\ 0,(t\in[t_3,t_4)) \\ -J_m(t-t_4),(t\in[t_4,t_5)) \\ -A_m,(t\in[t_5,t_6)) \\ J_m(t-t_6)),(t\in[t_6,t_7]) \end{cases} \tag{6}$$

$$A_{S(t)}=\begin{cases} A_m\sin^2(kt),(t\in[0,t_1)) \\ A_m,(t\in[t_1,t_2)) \\ A_m\cos^2(k(t-t_2)),(t\in[t_2,t_3)) \\ 0,(t\in[t_3,t_4)) \\ -A_m\sin^2(k(t-t_4),(t\in[t_4,t_5)) \\ A_m,(t\in[t_5,t_6)) \\ -A_m\cos^2(k(t-t_6)),(t\in[t_6,t_7]) \end{cases},k=\frac{J_m}{A_m} \tag{7}$$

Typically feed drive has a physical limitation on torque and velocity. And the parameter J_m should be given to generate trapezoidal acceleration motion profiles and sine-squared acceleration motion profiles. Here the three typical trajectory algorithms are used to generate a 50-rad-motion profiles with the parameters as follows：

$$V_m=120rad/s;A_m=2000rad/s^2;J_m=55000rad/s^3 \tag{8}$$

The position, velocity, and acceleration profiles and the frequency contents of the acceleration profiles are compared in Fig. 4. In trapezoidal and sine-squared acceleration profiles the high frequency contents are significantly reduced.

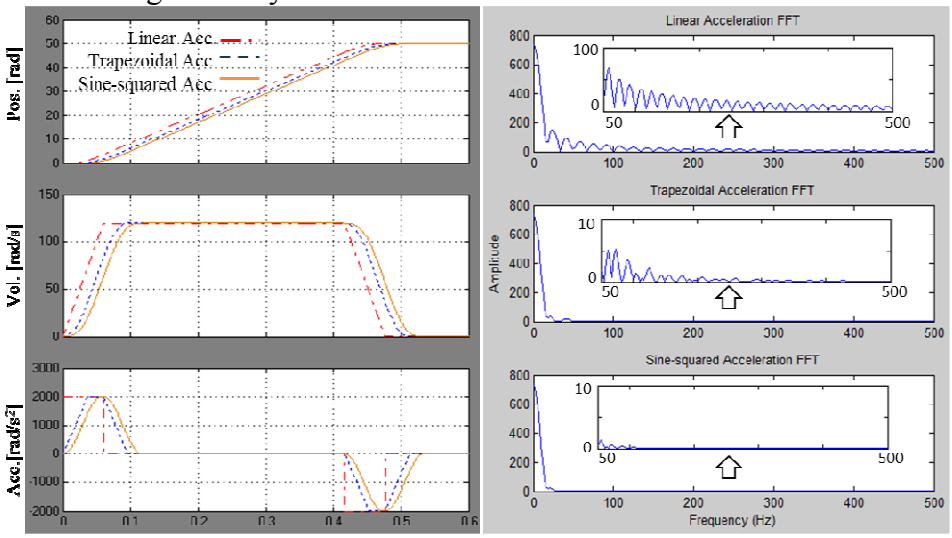

Fig. 4 Comparison of the three trajectories

Modeling and simulation of the feed drive system. Fig. 5 illustrates a Simulink model built according to the typical architecture of most feed drive control systems. Where K_{pp}, K_{vp}, k_{vi} and T_{rg} are the positional proportional gain, the velocity proportional gain, the velocity integral gain and torque command gain [7].The mechanical transmission system is set up as a dual inertia system as in fig.3. The nature frequency of the mechanical system can be calculated through Equation (4). T_L is set

as constant 0 to eliminate the effect of load on the system vibrations. The trajectory profiles in fig. 4 are added to the Simulink model with a nature frequency of 150 Hz of the mechanical system as motion command. The Comparison of the vibration and error of the simulation result are as Fig.6.

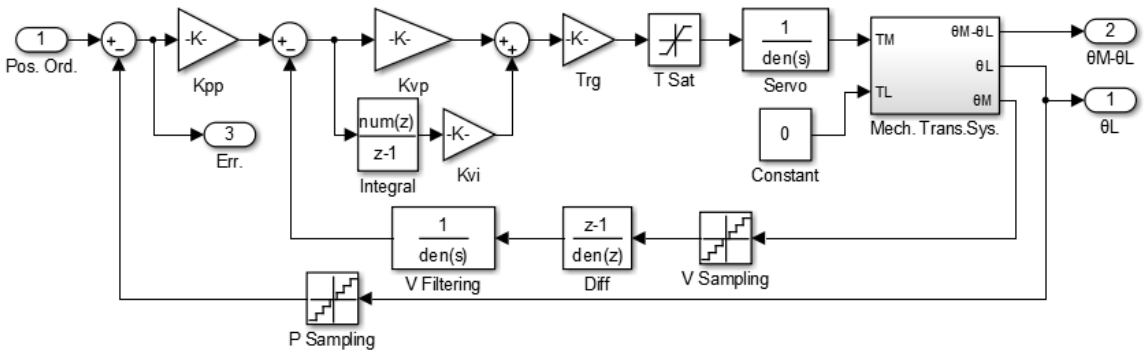

Fig. 5 Simulink model of the feed drive system

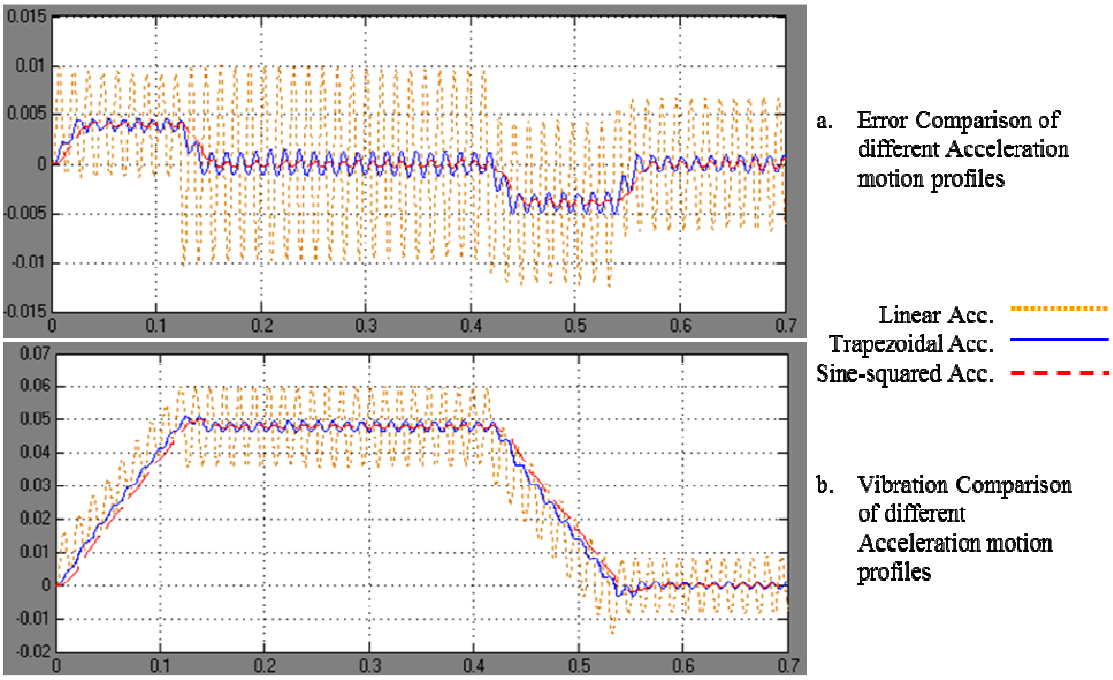

Fig. 6 Comparison of the vibration and error

Vibrations exist in all typical trajectories motions, but the motion of trapezoidal acceleration profiles and sine-squared acceleration profiles have much smaller vibration amplitude, and therefore the control error is significantly reduced.

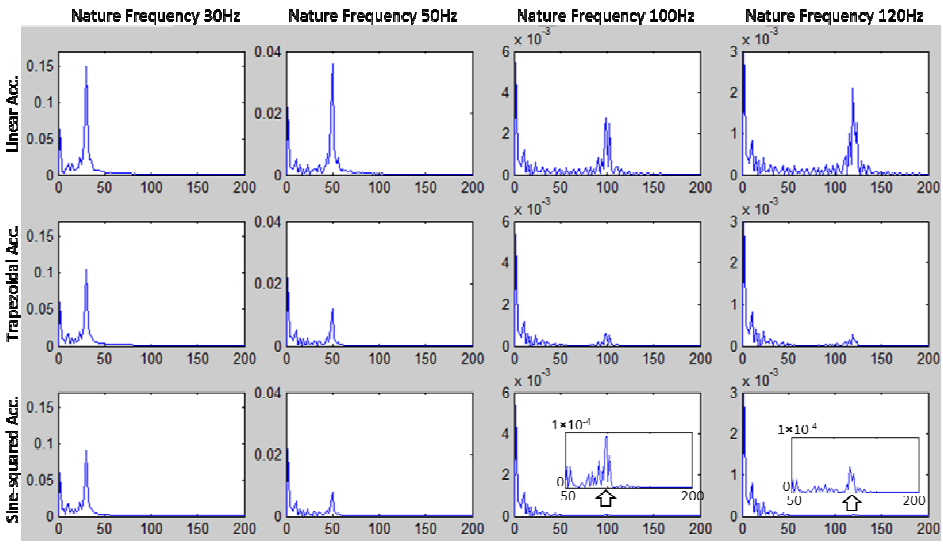

Fig. 7 Response spectrum analysis

Response spectrum analysis. The three typical trajectory motion profiles are given to the mechanical transmission system with nature frequency 30 Hz, 50 Hz, 100 Hz and 120 Hz as position orders. Fig .7 illustrates the frequency contents of the vibration $\theta_M - \theta_L$.

It's easy to find out that, vibrations of mechanical transmission system with nature frequency 30 Hz is excited by all the trajectory motion profiles but the vibrations are difficult to be excited when mechanical system has higher nature frequency and trajectory has smoother profiles. This means low nature frequencies of mechanical transmission systems must be avoided in order to keep the feed drive stable. The vibrations of mechanical system with high nature frequency can be avoided by using smoother trajectory profiles.

Summary

In this paper the vibration of feed drive is simulated by using a mathematic method. The mechanical transmission system is modeled as a dual inertia system. Three typical trajectories are used to analyze the effect of motion profiles on feed drive vibrations by using a simulation model of feed drive controller. Come to the conclusion that lower nature frequencies of mechanical transmission systems are easy to be excited to vibrations and must be avoided to keep the feed drive stable. The vibration of mechanical system with high nature frequency can be avoided by using smoother trajectory profiles.

Keywords: Moving target detection, moving target tracking.

Abstract. This paper compares two kinds of moving target analysis systems, which are the motion history image system and the moving object tracking system. Each system includes two parts which are moving target detection and tracking, achieving respectively detection of the direction of moving targets or representation of motion trajectory. Through experiment analysis of moving human and vehicles, each system is determined which situation it is suitable for.

Introduction

Target detection and tracking in image sequences has been a very popular issue in computer vision, image processing, pattern recognition and other fields. Target detection and tracking in image sequences means to detect every independent moving target in each frame image, or the area that users are interested in, and to locate these moving targets or area in the subsequent frames. It organically combines image processing, automatic control and information science. Besides it becomes a kind of technology that can automatically identify target from the image signal in real-time, extract target position information, and track the target movement. It can not only display motion direction and trajectory of the surveilled target, but also provide reliable data source for motion analysis of moving targets in the scene, and scene analysis[1].

Moving target detection is the basis for advanced applications such as target tracking, target classification, target behavior understanding. Its main purpose is to extract moving targets from video images and obtain feature information of moving objects, such as color, shape and contour. The process of moving object extraction is actually a kind of image segmentation. Since only in the continuous image sequences (such as video image sequences) the moving object can be seen, the process of moving object extraction is to find differences in the consecutive image sequences, and to extract the differences showed through object motion.

The subsequent step of target detection is target tracking[2]. Target tracking means while we do not know about the target motion information in advance, we estimate the target motion state in real time by the data from information source, so as to judge the position and movement of target. Moving target tracking is a complex estimation problem. At first it is mainly used for military research, because it is the key technology of precise weapon guidance. At present, with further study of image tracking technology, application of image tracking has penetrated into more and more fields such as visual surveillance and medical diagnosis. Studying a kind of target tracking method with good robustness, high precision, stable performance and powerful applicability is still faced with great challenges, and has important theoretical significance and practical value.

This paper compares two kinds of moving target analysis system, which are the motion history image and the moving object tracking. Each system includes two parts that are moving target detection and tracking. The motion history image system chooses frame difference method[3] as the method of moving target detection and algorithm based on motion template as the tracking algorithm. While the moving object tracking system selects background difference method[4] as the method of moving target detection and algorithm based on blob as the tracking algorithm[5]. Through detection of the motion direction or representation of motion trajectory of human and vehicles, each system is determined which situation it is suitable for.

The Motion History Image System

Frame Difference Method. The frame difference method is a motion detection method based on pixels. The difference operation of two or three adjacent images in a sequence of video images is performed to obtain the contours of the moving objects. From a theoretical point of view, the frame difference algorithm is actually a kind of dynamic edge extraction operation, while from a practical point of view, it can detect parts of contour information of moving objects. The frame difference method is adaptive to the dynamic environment, but in test results, it can not obtain all the feature pixels of moving objects. Besides the moving objects inside can easily cause holes, which is very bad for the subsequent operation.

First of all, use formula (2-1) to calculate the difference between the k image and the k-1 image, then get difference image Dk, and then use image segmentation algorithm formula (2-2) to binarize the difference image Dk. If a pixel value in the difference image is more than the threshold value, the pixel is foreground pixel, otherwise considered the background pixel. After that we can filter the binary image using mathematical morphology, and then get the image Rk. Finally analyze the regional connectivity of image Rk. When a connected area is greater than a given threshold, it is the target and that area of the region is the target minimum outside, so that we can determine the target rectangle.

$$D_k(x,y) = |f_k(x,y) - f_{k-1}(x,y)| \tag{2-1}$$

fk (x, y) and fk-1 (x, y) are the two consecutive frame images; Dk (x, y) is the frame difference image.

$$R_k(x,y) = \begin{cases} 0 & D_k(x,y > T) \\ 1 & D_k(x,y \le T) \end{cases} \tag{2-2}$$

T is the value of the image binaryzation threshold.

Tracking Algorithm Based on Motion Template. Tracking algorithm based on motion template, is on the condition that there is intersection between two adjacent frames of moving target in the screen. Targets in marine radar images and vehicles in crossroads both match the condition. This algorithm can clearly display the trajectory, velocity and direction of the target without extrapolation, correlation analysis and trajectory post-processing. The algorithm is based on moving target foreground image from moving target detection of the previous section. Specific process is described as follows:

1. Save detected foreground image and decrease the gray level of previous frames;
2. Add time stamp to the current frame and save it into historical image;
3. Form gradient image;
4. Segment gradient image to get the position of the target, calculate the gradient to obtain the velocity and direction of the target and add marker.

This algorithm simplifies the target correlation operation, can stably track targets without understanding target movement trend in the initial state, and also has better real-time performance.

Experiment Results.

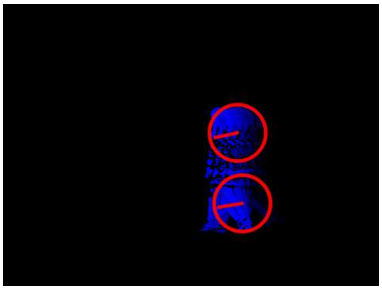

Fig. 1 Result of human tracking based on motion template

As we can see from fig.1, when detecting moving human in video images, tracking algorithm based on motion template has the problem that head and body are separately detected. And in the experiment results, the detected motion direction in most cases is correct, but in the several starting and ending frames of the video the direction is wrong.

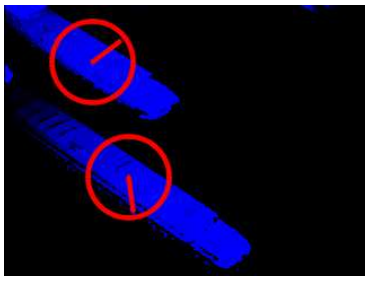

Fig. 2 Result of vehicle tracking based on motion template

As can be seen from fig.2, the detected direction of moving vehicles in video image is wrong in most cases by using tracking algorithm based on motion template. That means tracking algorithm based on motion template is not suitable for detection of targets that move too fast.

The Moving Object Tracking System

Background Difference Method. Background difference method compares the input image and the background image to detect moving targets. Since the background difference method is simple, fast, and can completely detect targets in most cases, it has become the most widely used motion detection method.

In order to solve problems of frame difference method and improve detection effect, the background difference method has been developed.

The principle of background difference method is very simple. Firstly use the formula (3-1) to calculate subtraction of the background image fbk and current frame image, then according to the formula (3-2) binarize the difference image Dk and filter it using mathematical morphology, and analyze regional connectivity of the result Rk. When a connected region area is greater than a given threshold, it is the target and that region is the target area, so we can determine the minimum enclosing rectangle of the target.

$$D_k(x,y) = | f_k(x,y) - f_{bk}(x,y) | \tag{3-1}$$

Fk (x, y) is two consecutive frames, and Dk (x, y) is the frame difference image.

$$R_k(x,y) = \begin{cases} 0 & D_k(x,y > T) \\ 1 & D_k(x,y \le T) \end{cases} \tag{3-2}$$

T is the value of the image binaryzation threshold.

Tracking Algorithm Based on Blob. The basic principle of tracking algorithm based on blob is to segment the candidate pixel, judging whether the pixel belongs to the target, the background or other areas. Tracking algorithm based on blob can also be called tracking method based on image segmentation, because it has the same way with image segmentation, which is to optimize pixel selection, combination and separation according to the given clues, and to gather the pixels with the same feature into a region. It has difference with the traditional image segmentation. Visual object tracking is to locate the target in image sequences. It can be not accurate in pixel classification on a certain degree, because it only needs to segment results to distinguish target from background, while the traditional image segmentation algorithm needs to accurately display the target contour. Segmentation cues generally include target movement characteristics, texture features and image depth information.

In many applications, we hope to detect the moving objects, number them and track them, finally get the motion trajectory. In order to achieve the aforementioned function, based on the knowledge we discussed before, we can subdivide the whole process into the following modules, which are foreground detection module, new blob detection module, blob tracking module, trajectory generation module and trajectory post-processing module.

The foreground detection module of moving objects is to judge whether a pixel is foreground or background. Input data is the current frame image, while output is foreground mask of the current frame. OpenCV can detect completely stationary background. In practical application background is possible translated or rotated, in order to meet the background changes, we need to use the camera calibration. The foreground detection module divides the pixels of current frame into foreground and

background. A moving object is considered as the foreground, while unchanged parts in the video as the background region.

The blob feature detection module of moving objects is to detect blob, a collection of pixels of motion objects in a scene using results of foreground detection. Input data is the mask of current frame and existing blobs, while output data is the blob newly detected. In order to meet the application in radar system, graphic features and motion correlation analysis of blob should be taken into consideration, in addition the operation after fusion among blobs and between blob and background pixels should be considered. This module can detect new blobs according to the current foreground mask, like the objects newly coming into the scene.

The blob tracking module of moving objects includes blob list and a single blob tracking. It uses the results of new blob detection. The input data are the current frame, the mask of current frame and the new blobs, while output data is the blob information of current frame, including ID, position, speed and direction of movement.

The trajectory generation module is to collect position information of all the blobs, establish the trajectory list and deal with the correlation processing. The purpose of this module is to save the whole trajectory into a specified file, and also to calculate some data of each blob (using the original image and the foreground mask) and save them. Input data of trajectory generation module is all the blobs in the current frame, while output data is the trajectory list we have saved.

The trajectory post-processing module is to remove the jitter of position and motion trend when marking moving objects, and smooth the trajectory. Input data of trajectory post-processing module is all the blobs in the current frame, as well as the output data.

This module can be used as glue, because it can bind other sub-modules into a complete process.

Experiment Results. Target tracking algorithm based on blob is aimed at detecting and tracking multiple moving targets in video image. Compared with the tracking algorithm based on motion template it is more complex, and widely used.

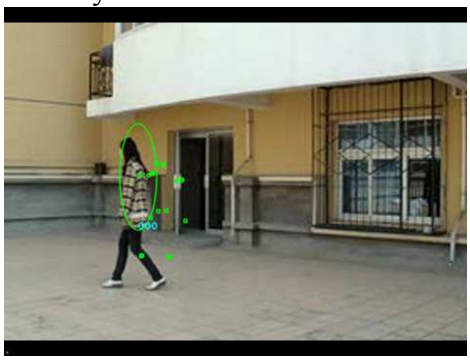

Fig. 3 Result of human tracking based on blob

Fig.3 is the result of human motion tracking by using tracking algorithm based on blob. It is observed that this algorithm on detecting and tracking moving body is basically right, but still has the problem that head and body are separately detected. Small rectangles in picture show the center of detected motion target in several video frames. Due to the above-mentioned problems, tracking algorithm based on blob can not accurately display the motion direction and trajectory of moving body.

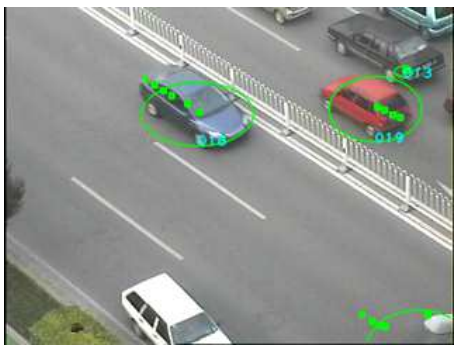

Fig. 4 Result of vehicle tracking based on blob

Fig.4 is the result of vehicle motion tracking by using tracking algorithm based on blob. As can be seen from the picture, the detection and tracking of moving vehicles in video image is correct in most cases, and the algorithm can mark the moving targets. But sometimes the vehicles newly coming into the picture can not be detected and tracked. For the rigidity and integrity of vehicle target, tracking algorithm based on blob can correctly display the motion direction of target and present part of the trajectory in video frame.

Conclusion

With the above discussion of algorithms and experiment results, we can reach the conclusions:

When it comes to the motion history image system, tracking algorithm based on motion template applies to detect and track simple single moving target. Comparing the results of human motion tracking and vehicle motion tracking, the motion history image system is more suitable for detecting and tracking human that moves slowly, and it can correctly display motion direction.

When referring to the moving object tracking system, tracking algorithm based on blob is a little complex and it is suitable for detecting and tracking multiple moving targets in video image sequences. We have introduced each module of tracking algorithm based on blob, realized the detection and tracking of multiple moving objects in video, and shown the motion direction of each moving target, as well as part of the trajectory. This algorithm has some problems on tracking moving body. It can not detect the complete human body, therefore the moving object tracking system is not suitable for detection and tracking of human motion.

Moving target detection and tracking usually is used as a pre-treatment technology of visual object behavior understanding and description, and other advanced processing technologies. In recent years, although scholars have done lots of researches, but due to the complexity of target surroundings, as well as the target itself possible transformation, and the influence of weather, illumination, shadow and other natural conditions and human disturbance, the target detection and tracking technology is still a complex process, and a difficult issue needed further researches.

Keywords: Upper cover of clamshell phone; dual-mode; side gate; inner slider; inclined pushing rod.

Abstract. The design of injection die on the upper cover of clamshell phone is introduced. The dual-plate die has side gate for opposite glue injection, the parts are ejected by ejector pin, the side reversed buckle contains three blocks, the reversed buckle at flip shaft consists of two inner sliders, and all the eight inner reversed buckles are made up of inclined pushing rods, and the cooling system embraces "U" shaped cooling waterway. Its application in practice has proved the reasonable die structure, smooth remolding, and qualified plastic part design.

1. Analysis of plastic part process

The upper cover of clamshell phone is shown in Fig. 1. It is made of polycarbonate PC .This medium-and small plastic part's size: 78.02 mm × 43.22 mm × 8.04 mm (L*W*H). The two outer reversed buckles on the head of plastic part (Fig. 2) consist of sliders; the inner reversed buckle at the shaft of the head (Fig. 3) is made up of inner sliders; the inner reversed buckle on the head (Fig. 4) is composed by inclined pushing rod; the product's two side edges respectively wear two outer reversed buckles (Fig. 5) formed by side sliders and two inner reversed buckles (Fig. 6) formed by inclined pushing rods, and the tail wears two inner reversed buckles (Fig. 7) composed by inclined pushing rods.

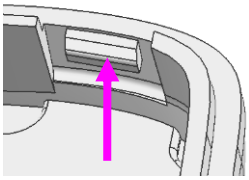

Fig. 7 Inner reversed buckle on the tail

2 Design of the die structure

2.1 Design of gating system and parting surface

The overall structure of the die is shown in Fig. 8. This dual-plate die with 1 cavity has side gate for glue injection, the parts are ejected by ejector pin. When the parts are well modeled, the gate will be sheared. In order to not hinder the assembly by the shearing of gate, a shallow groove is needed for glue injection. The maximum parting line is the maximum contour line; since the product maximum contour is also the product's bottom boundary line, so the maximum parting surface is the bottom surface of the product

2.2 Design of main parts

The main parts of the die include cavity (No. 16), core (No. 17), three side sliders, eight inclined pushing rods and two inner sliders. The cavity (No. 16) is embedded in the cavity plate (No. 7), and the core (No. 17) is inlaid in the core plate (No. 3) This design allows easy processing and die repair, and low cost. The three side slider's glue injection gates and the sliders are relatively small, so integral design is preferred. Due to limited space, the strength of the inner slider's head is weak (Fig. 9), so iron is added at the head's non adhesive position to improve the slider head's strength (Fig. 10). The part's material depends on the amount of products. Large amount of products should be made of good materials, and heat treatment is required; while the medium or small amount of products can be made of cheaper materials. The cavity should be made of harder material than the core, so that the cavity won't be destroyed by the product's surface.

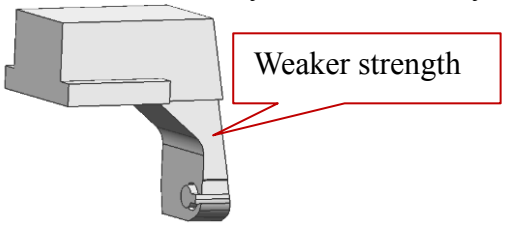

Fig. 9 Inner slider

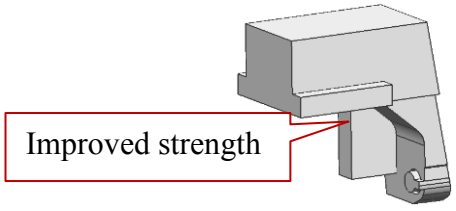

Fig.10 Slider (with improved strengthen)

2.3 Design of inner slider's structure

The design of inner slider's structure is the difficult and key part of the die. The inner slider's structure is shown in Fig. 11.

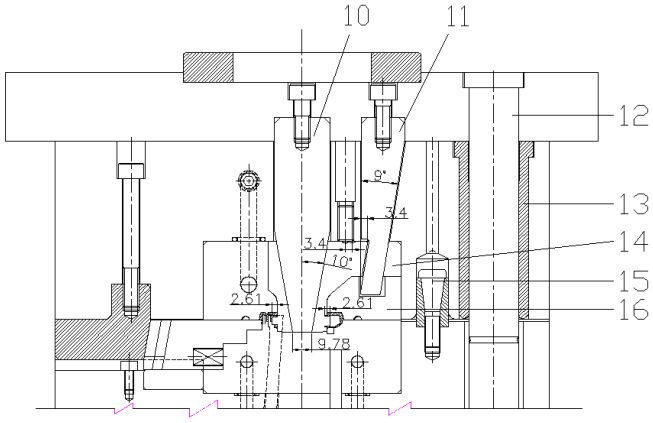

Fig. 11 Inner slider's structure

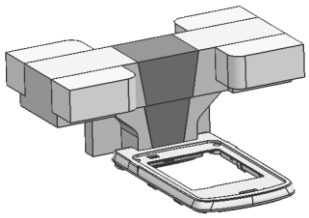

Fig. 12 3D structure of inner slider

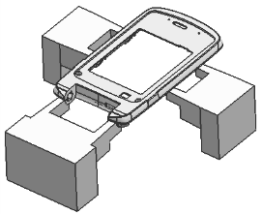

Fig. 13 3D structure of side slider

The size of two reversed buckles of inner slider is 2.61mm. Usually, the slider's backward distance = reversed buckle's size + safety value for 1 ~ 2mm; if the safety value is 2mm, then the inner slide's backward distance should be: 2.61+2=4.61mm, which means the minimum distance between two inner sliders is 9.22mm. In order to avoid the interference between the two inner sliders after demoulding, safe distance should be designed. The thickness of inner slider's weakest part should be 5mm or above, then the two sliders' total backward distance is only 9.78mm, the safe distance between two inner sliders is only: 9.78-9.22=0.5mm. This is not safe or reasonable, so the sliders' backward distance should be properly reduced. When the safe value is 0.8mm, the sliders' backward distance is: 2.6+0.8=3.4mm, the distance between the two inner sliders is: 9.78-3.4*2=2.98mm. This is relatively reasonable. The wedge block's angle (at single side) should be larger than the inner slider's pin's by 1 ~ 2 °. According to the inner slider's height and backward travel, the inner slider's pin's angle is 9 °, the inner slide's wedge block's angle at single side is 10 °. The slider travel is limited by Tsai screw. The 3D structure of inner slider is shown in Fig. 12 (excluding the pin and positioning screw).

2.4Design of side slider's structure

Product head's two outer reversed buckles are respectively formed by a side slider, its two side outer reversed buckles are also respectively formed by a side slider whose 3D structure is shown in Fig. 13 (excluding the side slider seat, pin and inclined guiding pillar).

Design of side slider's structure: (1) The three side sliders contain two reversed buckles, and the slider's backward travel= reversed buckle's size + safety value for 1 ~ 2mm. (2) The side slider's driving mechanism can be inclined guiding pillar or "T" shaped block, and here the latter is adopted. The wedge block is directly processed as "T" shaped block, and slider's seat is processed into "T" slot, with inclined guiding pillar eliminated. This process is complicated. The calculation of parameters of side slider is shown in Fig. 14. $\alpha \leq 25$, S1=S3+1 ~ 2mm, S2=h*tg α =S1, α (Note: α is the inclination angle of "T" slot, S1 is the distance between limited screw and slider, S2 means the slider's backward travel, S3 is the size of reversed buckle, h refers to the height of "T" slot). In order to ensure correct resetting of sliders, S1 =S2. Since the maximum size of all the side sliders' reversed buckle is 1.02mm, so S3=1.02mm, S2 = 3mm, α =10 ° is preferred according to the height of the slider, h=18mm, so as to meet the design requirements. (3) The sliders should be installed with limiting spring, to ensure the correct position of sliders influenced by limiting spring and limiting screw as well as smooth opening and closing demoulding.

2.5 Design of inclined pushing rod

All of the 8 inclined pushing rods' inner reversed buckles can mode the buckles and eject the products. The plane structure of inclined pushing rod is shown in Fig. 15.

Design of inclined pushing rod: (1) If reinforced bar leis behind inclined pushing rod, the inclined pushing rod should be ensured with enough space for backward movement without interference with the reinforced bar, namely S2>S3. (2) The calculation of parameters of inclined pushing rod: S3=S1+1 ~ 1.5mm (safety value), S3=h* tgα, wherein S3 is the backward travel of inclined pushing

rod, S1 is the size of reversed buckles, α is the angle of inclined pushing rod, h is the ejection height of inclined pushing rod. The eight inclined pushing rods allow different inverted values but the same ejection height, thus the design should enable the inclined pushing rod to safely exit from the reversed buckles and ensure normal use.

2.6 Design of exhaust system

Mobile phone shell requires high accurate surface. In order to ensure good surface quality, exhaust system is usually required. The exhaust system of cavity is usually designed into the following forms: (1) In case of the die's plane parting surface, deep exhaust groove can be milled at the position 5-8mm away from the molding position, and then the plane grinding machine grinds the shallow exhaust groove lying between the molding region and the exhaust groove; the grinding depth is less than 0.03mm, the width is less than 10mm (Fig. 16). (2) The gap between inserts can be used for exhaust (3) The gap between the pushing rod and the core can be used for exhaust.

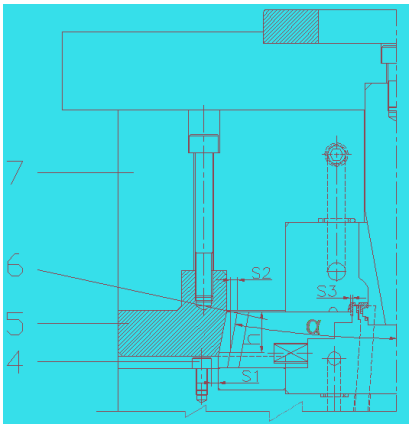

Fig. 14 Plane structure of side slider

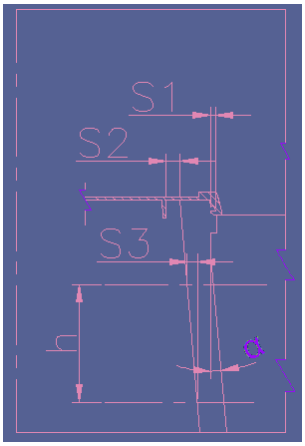

Fig. 15 Inclined pushing rod

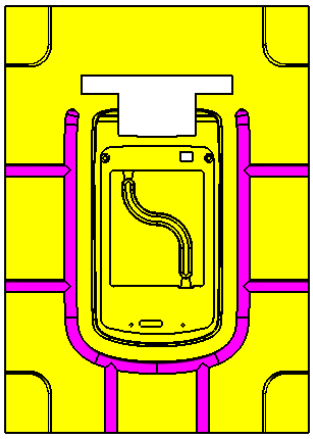

Fig. 16 Exhaust system

2.7 Design of cooling system

In the process of injection for molding, the temperature of melt in the cavity is generally 200 ~ 300 ℃. In order to enable rapid cooling and molding of the melt, the die's temperature shall be cooled to 60 ℃ before the products are taken out. In order to shorten the molding cycle, the die should be cooled.

As is demonstrated by the experiments, of all the heat transferred from plastic parts to the die, about 5% is diffused to the air by radiation and convection, 95% is taken away by cooling medium. The cooling time, pipe's diameter and length of pipe in cooling system can be calculated.

The parameters of cooling system are usually not determined by calculation, but by empirical value. Plastic phone housing requires high quality surface, so cavity and core both require cooling water channels. Since the product is not big, and one die contains only one cavity, the cooling water channel is designed into single "U" shape, and the channel diameter is 8mm. In order to ensure good cooling effect, usually the die's temperature is controlled at around 60℃ by the system of injection molding machine, and the temperature gap between inlet and the outlet should be less than 5℃.

2.8 Design of ejection system

The plastic product is shallow, with many low bars, so ejection rods are preferred for ejection. The main principles for location of pushing rods: (1) They should be placed at the position with thick glue; (2) They should be placed at the high position with more bars and greater holding force; (3) They should be placed in balanced manner, for balanced ejection force; (4) Round pushing rods are preferred, and only flat ones with simple specifications are preferred only at high bar position.

2.9 Design of guide positioning system and resetting mechanism

Guiding and positioning system guarantee the accuracy and life span of the die. The guide components comprise guiding pillar (No.12), guiding sleeve (No.13), side lock (No.25), cavity (No.

14), core's (No.17) positioning mouth. The resetting mechanism consists of resetting spring (No.19) and resetting rod (No.20). These positioning parts and resetting mechanism ensure the precision of die, the quality of products and the service life of die.

3 Opening and closing process of die

The plastic melt is injected into the die's cavity via the nozzle; after the injection, pressure holding, cooling and solidification, the die is opened. In the opening process, under the influence of nylon buckle, the fixed template is firstly separated from the fixed mode's seat plate for the first parting, then the inner slider's wedge block (No.10) is separated from inner slider (No. 14), and the fixing mode's seat plate (No.8) drives the inner slider's pin (No. 11) and the inner slide (No. 14) to demould the reversed buckle; then continue to open the die, under the influence of travel rod (No.24) and screws of the same height (No.23), the fixed template is separated from the movable one, for the second parting; finally, the pushing rod ejects the products. In the closing process, firstly the fixed mode's template (No.7) and fixed mode's seat plate (No.8) are closed, followed by the fixed template and the movable one.

4 Conclusions

The dual-plate die has side gate for opposite glue injection; the two inner sliders' shaft for moulding wear reversed buckles. The outer reversed buckles at the three sides are made up of sliding blocks. The 8 inclined pushing rods wear inverted buckles, and the parts are ejected by pushing rods. The real application has demonstrated the reasonable structure of die, stable production, and qualified plastic part design.

Keywords: 4-DOF manipulator; PMAC; openness

Abstract. To complete the step of pacing bolts more accurate and efficient in factory, This article design the 4-DOF manipulator Based on PMAC motion controller, including hardware architecture, software architecture. This control system combines the IPC strong management and real-time control of PMAC to achieve a 4-axis robot, smooth fast-precision, high efficiency, high reliability, cost-saving design goals.

Introduction

In currently, Placing bolts in the domestic mechanical assembly process step used mainly done manually or three degrees of freedom manipulator controlled by PLC completed. Manual processing could ensure various types of boltscan be placed in any positionin three-dimensional space, but it has low efficiency and high cost. When using three degrees of freedom manipulator processing controlled by PLC, we will get higherefficiency,but lower scrap rates and costs.Due to structural limitations of three degrees of freedom manipulator, boltsinstalled only in the two-dimensional plane limited locations. This design basing on PMAC programmable multi-axis motion control card controls to achieve a 4-DOF manipulator completes bolts placed in anywhere of three-dimensional space, and higher efficiency, lower cost

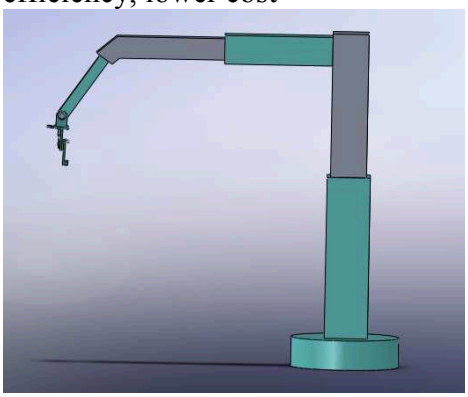

Fig. 1 Manipulator simulation diagram

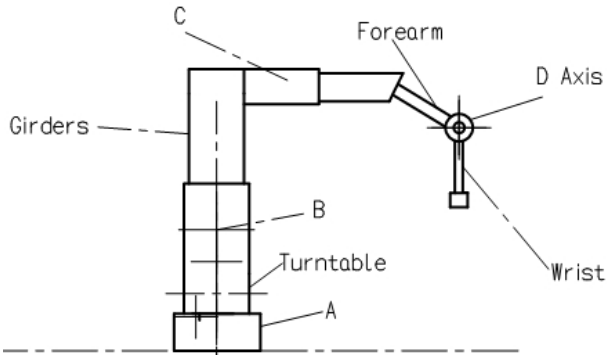

Fig. 2 Manipulator organization chart

4 DOF manipulator mechanical structures

4-DOF manipulator including industrial control computer, PMAC programmable multi-axis motion control card, servo drives, AC servo motor, single-stage small hydraulic cylinders, hydraulic cylinder drives and encoders, rotary devices and other components bearing hardware platform. Manipulators mechanism shown in Figure 2.

Themanipulator and the clamping mechanism are drived by hydraulic cylinder to drive the joints to complete trajectory. The mechanical arm islong, generating larger torque, so we choose a large area of circular base, enhancing the stability of the structure and design the turntable, girders, forearm, wrist and rack and pinion mechanism to achieve a good manipulator work. Throughout themanipulator are installed at the bearing rotary table, slewing achieves 360-degree rotation around the axis A drive by a servo motor through the inner gear .the manipulator equipped with encoder to feedback rotational

speed, angle. The frame, arm and wrist, all driven by hydraulic cylinders, to achieve the B C D three degree of freedom motion, so as to ensure adequate operating range and the accuracy of the movement. Manipulator gripping mechanism shown in Figure3.

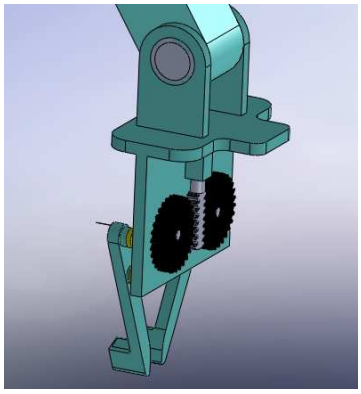

Fig. 3 Rack and pinion clamping mechanism

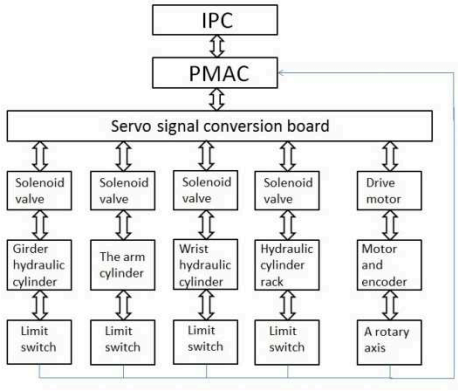

Fig. 4 Control system structure

The clamping mechanism of manipulator use rack and pinion to keep the clamp arm opening or closing .instead of the direct driving by motor available in the market. A double-sided rack rigidly connected to the cylinder, double-sided rack driven by a hydraulic cylinder for reciprocal motion, double-sided rack mesh with two gears respectively, keeping the clamp arm opening or closing. When the cylinder moves to the Bottom, the clamp arm closes to the minimum angle, completing gripping action. When the cylinder block extends to the longest position, two clip arms open to the maximum angle, completing release action.

Manipulator available on the market usually use motor-driven, but the vibration caused by the motor is large, leading the system unstable. Hydraulic cylinder 's vibration is smaller than the motor's , the system also be more stable, In order to reduce the vibration caused by the motor and improve the accuracy of the Manipulator, the Manipulator is driven primarily by hydraulic cylinders driven , keeping smooth the Manipulator operation, quickly. Compared with the motor driving, cylinder driving omitted gear mechanism, getting the simpduce the weight of the body and the required stiffness of the Manipulator. Save manufacturing costs asle mechanism and high reliability of the Manipulator. Omitting the gear unit can re well.

Control system hardware design

The control system uses the upper and lower two control devices, IPC and PMAC programmable multi-axis motion control card. IPC has the computing capacity, stable operation and fast response; while PMAC has the strong ability to handle real-time tasks, controlling motion directly. IPC connects PMAC via a data bus [1]. Upper and lower levels, the control device designed in this paper, can make good use of the advantages of IPC and PMAC to achieve 4-axis joint movement, meet the high precision, fast movement requirements. The system selects Mitsubishi synchronous AC servo motor, and equips with encoder providing speed and position feedback. Small hydraulic cylinder drive beams, arm, adapter. On the same time the gripping arm has a small hydraulic cylinder, driving a rack to achieve the gear operation, so that the clamp arm works smoothly. The structure of the control system shown in Figure 4.

Software designs of control systems

Software system structure. System software can be divided into two categories, the one is IPC as the core management software, the other one is PMAC as the core of motion controlling software, they consist of the host computer and the next crew hierarchical control framework. IPC has these responsibilities for managing system, setting initialization parameter of system, communicating between the PMAC and IPC, monitoring system status, and controlling by man-machine interface to achieve the function of automatic controlling, manual controlling and real-time showing of the state

of motion. PMAC has these responsibilities for the real-time motion controlling system, including the trajectory controlling, speed controlling, servo-loop real-time updating, security procedures. The main function of the Manipulator software system is completing motion controlling tasks to ensure the normal operation of the 4-DOF manipulator grip, through management and real-time control of digital machines PMAC host computer.

IPC software. 4-DOF manipulator IPC software is developed by VC Windows platform + + Prepared, Stored in the IPC (IPC). The IPC calls Pcomm32 achieve system initialization function achieves, real-time monitoring system status, system communication and manual control functions

(1) System initialization module. System initialization module download via dynamic connection Pcomm32 program functions provided from Delta. System initialization files in the IPC hard drive are stored directly to the downloaded to PMAC, initializing the PMAC, and activating the next crew program. We also can set PMAC parameters directly [2].

(2) System monitoring module. This system monitoring module can samples the various parameters of the Manipulator in real time, and reflects in the interface, these parameters include the position of each cylinder, stretching speed, pressure, motor position, speed and Alarm information. The monitoring module is also charged with the task of system communication bus. PMAC communicates with the host computer through dynamic link library PComm32.PComm32 contains all methods of communication with the PMAC, including PMAC.dll, PMAC.says, PMAC.vxd. it also contains more than 250 function. [3.], but we only need grasp the following functions which can achieve most of the communication function, shown in Table 1.

Table 1 PMAC Program function figure

	Function code	Function
1	BOOL OpenPmacDevice(DWORD dw De-vice)	Open communication channel for the program using PMAC
2	BOOL ClosePmacDevice(DWORD dw De-vice)	After the program ran, this function closes the open channel
3	BOOL PmacSetMotor (HWND hwnd,DWORDdw Device)	This function can set PMAC communication with the host computer:buscommunication or serial communication
4	Void PmacSendCommandA(DWORD dw Device, PCHAR command)	This function may send a command to the specified PMAC directly, the parameters of the command are strings

(3) Manual control module. Manual control module function like a conventional manual CNC system control panel, so as to established a human interactive interface. Users can send commands directly to the manipulator module to achieve jogging, precise positioning, reset, suspend sports function. precise positioning means input pinpoint the exact coordinates in the coordinate system,so that the hydraulic cylinders can reach the specified location, while using a feedback signal to the comparator to ensure the positioning accuracy. By changing these PMAC I variables to control the speed.

Manual function achieve its function by calling PComm32 PmacGetResponseA (DeviceNumber, response, 255, "string") to achieve, changing the string to the PMAC. Among them, jog's string is "# n j +" or "# n j-"; precise positioning's string is "# n 172 -> L: $ 082B" [4].

PMAC Control module. PMAC motion programs can be interpreted by the G code interpreter, M code interpreter or T code interpreter,it also can be edited by PEWIN32 software. This design of the manipulator is edited via a PMAC program for editing text editor and a PEWIN32 PMAC serial terminal interface oriented interface. PMAC motion control program is developped and debugged by PEWIN32 executing software, including position control, speed control, servo loop update, security and other real-time tasks.

PMAC can support up to 256 motion programs, arbitrary coordinates can execute at any time any such a program. you first define the coordinate system and the shaft, One or a group of synchronous motors for the same purpose of organizing consisted of the PMAC coordinate system. By definition statement for the motor shaft axis to create a coordinate system assigned. Secondly, according to the requiredmotion, PMAC selects the appropriatemotion commands, and then follows thesyntax for writingPMACmotion programs,downloads toPMACmemory, the last run

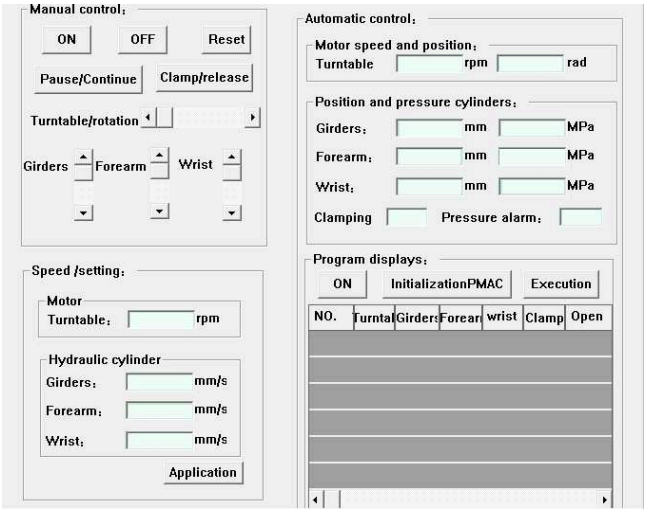

Fig. 5 Interface

Summary

This paper presents a 4-DOF manipulator based on PMAC controller. The Manipulator is driven primarily by hydraulic cylinders driven rather than motor driven, keeping smooth the Manipulator operation, quickly. Cylinder driving omitted gear mechanism, getting the simple mechanism and high reliability of the Manipulator. Omitting the gear unit can reduce the weight of the body and the required stiffness of the Manipulator, save manufacturing costs as well. Control system hardware and software has been designed .The IPC (IPC) as the core of management to manage the host computer system software; The PMAC as the core of components of lower machine to control the real-time motion. They constitute the host computer and the next crew hierarchical management framework so as to combine the dual advantages of IPC and PMAC. Compared with the conventional PLC controlling Manipulator, it improves the response speed, shortens the response time, enhances multi-tasking capabilities. We also design the PMAC interface, write software. After the simulation, the system is running well

Keywords: impregnated diamond bits, specific energy, uniaxial compressive strength, drilling mechanism.

Abstract. Impregnated diamond core bits are often used in core drilling for geological surveys. A tri-state theory is proposed to describe the three states in drilling processes for a diamond particle or a bit. These states are contacting state, cutting state, and ploughing state. Furthermore, the relations among thrust and other mechanical parameters are also summarized. The optimal value of the specific energy is in the cutting state. Several experiment results verified the proposed model. This mechanism is useful for selecting operation parameters in core drilling using impregnated diamond core bits.

Introduction

Geological surveys are important for the purpose of creating a geological map or model in petroleum fields, coal mines, and civil engineering constructions. Although various methods have been proposed for geological surveys in the past decades, core drilling is still the most intuitive and reliable advanced geological forecast technology. For core drilling, impregnated diamond core bits are often used. Therefore, it is important to elucidate drilling mechanism for the selection and design of diamond impregnated bits. In particular, quantitative knowledge related to drilling processes such as penetration rate and resistance forces are indispensible.

Nishimatsu discussed the relations between the penetration speed and operational parameters of the drilling for several types of bits [1]. And, the relation for impregnated diamond bits was summarized as the following:

$$F_t=\mu F_N \tag{1}$$

Herein, F_t is the circumferential force, F_N is the thrust force, *and* μ is the friction coefficient in a broad sense. Meanwhile, we have

$$F_N=\sigma_c u \Delta r, \tag{2}$$

where σ_c is uniaxial compressive strength (UCS), u is penetration per revolution, and Δr is the width of the bit blade.

Eq.(1) shows that a drilling process of an impregnated diamond bit can be regarded as a friction process between the bit and the rock, and the principal force (torque/radius) is proportional to the thrust force. Eq.(2) shows that the thrust force is proportional to the product of UCS and penetration per revolution. These two equations are succinct, and can be applicable to a certain extent. But they cannot describe the complex relations among mechanical parameters and rock strengths precisely. Several studies reported that the proportional relations as shown in Eq.(1) and Eq.(2) are valid only in a limit range of trust forces [2-4], but the bit-rock interaction mechanism for impragnated diamond bits was not illustrated.

Mechanism of Impregnated Diamond Bits

Three States in the Cutting Process of a Diamond Particle. Using small-diameter impregnated diamond bits, several drilling experiments were conducted, and the drilling processes were observed. Based on the results, a bit–rock interaction model for impregnated diamond bits was proposed. According to this model, a cutting motion of a diamond particle is divided into 3 states by the penetration depth as shown in Fig.1. In this figure, *h* is the pop-out height, and *d* is the penetration depth into the rock.

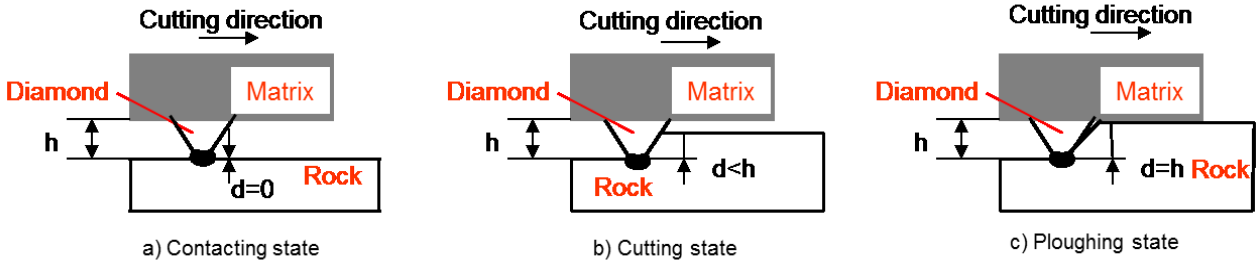

Fig.1 3 states in cutting process of a diamond particle

Contacting state (*d=0*)

In this state, the diamond particle is contacting to the rock lightly. The matrix is separated from the rock. Friction is the main bit-rock interaction pattern while cutting action can be ignored.

Cutting state (*d<h*)

The diamond particle penetrates into the rock. Friction still exists, but cutting becomes the main action. The matrix is separated from the rock.

Ploughing state (*d=h*)

The exposed portion of the diamond particle penetrates into the rock entirely, and the bottom of the matrix around the particle contacts the rock completely. There is ferocious friction between the matrix bottom and the rock. Cutting and friction occur at the same time.

Three states in the cutting process of an impregnated diamond bit. The model is shown as Fig.2.

Contacting state (*d=0*)

Some diamond particles are contacting to the rock lightly while others not. The matrix is separated from the rock completely. Friction is the main bit-rock interaction pattern while cutting action can be ignored.

Cutting state (*d<h*)

Some diamond particles penetrates into the rock while others not. Friction still exists, but cutting is the main action. The mmatrix is separated from the rock.

Ploughing state (*d=h*)

Exposed portion of all diamond particles penetrates into the rock entirely, and the bottom of the matrix around the particle contacts the rock completely. There is ferocious friction between the matrix bottom and the rock. Cutting and friction occur at the same time.

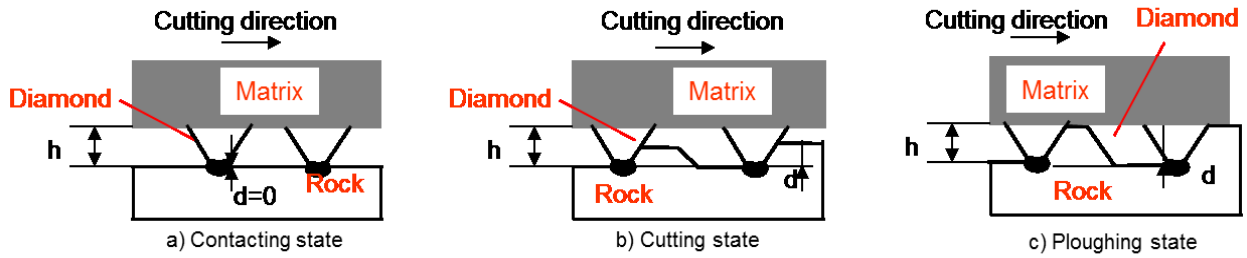

Fig.2 3 states in cutting process of impregnated diamond bit

Relations among Mechanical Parameters in Each State

In above chapter, the definition of the tri-state theory was proposed. For actual processes of drilling, each state may occur depending on the thrust. The exposure degrees of particles vary, hole-bottom surface is irregular, and the states of the particles are different with each other. Therefore, it is impossible to precisely describe the state for each particle. Nevertheless, basic behavior of each state of the bit can be described.

In this paper, drilling parameters discussed are explained as follows.

P: Principal component force, or conferential resistant force, torque / radius (N).

Q: trust, the resistant force in the penetration direction. (N).

u: penetration speed. (mm/s).

d: penetration rate, or penetration depth per revolution. (mm).

SE: specific energy. It is defined as the amount of work necessary for removal of a unit volume of rock. The specific energy can be expressed as shown below [5]. （MPa）

$$SE = \frac{Q}{A} + \frac{2\pi NT}{Au} \tag{3}$$

Therein, *T* is the torque, and *A* is the effective cross-sectional area of the hole. Here, effective cross-sectional area means the area of the circular loop formed by the outer and inner radii of a bit.

Relation Between the Principal Force and Thrust. We propose an equation to express the relation between the principal force and thrust in drilling processes using diamond bits as the following:

$$P = fQ \tag{4}$$

Herein, f is friction coefficient in a broad sense. This equation is the same in shape as Nishimatsu's equation. Meanwhile, we have

$$P = P_c + P_f = P_c + P_{df} + P_{mf} \tag{5}$$

The principal force P consists of cutting force P_c and friction force P_f. The latter includes two parts: the friction force between the bottom of the particle and the rock P_{df}, and that between the matrix and the rock P_{mf}. Furthermore, about friction coefficients, we have

$$f = f(f_c, f_{df}, f_{mf}), \tag{6}$$

Herein, f_{df} is the friction coefficient between particles and rock, f_{mf} is between matrix and rock, and f_c is the ratio of the cutting force and trust. This equation shows that general friction coefficient f is the function of f_c, f_{df}, f_{mf}.

For a contacting state, $P_c=0$, $P_{mf}=0$, the principal force is

$$P = P = P_c + P_f = P_c + P_{df} + P_{mf} = P_{df}$$

Theoretically, there is no cutting action in this state, and the bit removes rock mainly by grinding and friction of diamond particles. Depth of drilling per revolution is near zero. Thus the specific energy is significant.

In a cutting state, with the increasing of thrust, torque and penetration rate also increases proportionally. According to Eq. (3), the specific energy keeps constant.

In a ploughing state, penetration rate reaches its maximum value even though that thrust continues to increase. Torque from friction is increasing while penetration rate is constant, thus the specific energy increases significantly.

Indoor Experiment Results

Experimental devices. To measure mechanical data, several drilling experiments were conducted using a bench drilling machine (HITACHI B13RH) equipped with a displacement sensor, a torque sensor, a tachometer, a load meter, and an electricity meter. Four types of impregnated diamond bits, 5mm, 10mm, 20mm and 30mm in diameter respectively, by Asahi Diamond Industrial Co., Ltd., were used. Rock specimens were taken from sulfide minerals. UCS is in the range of 10-22MPa, the porosity is 20-30%.

Experiment method and process. The rotary speed was set to 580r/min. Thrust was changed from 0 N to 600 N. The hole depths were greater than 80 mm. Water was used as cutting fluid. Signals of these sensors were amplified through an amplifier circuit. They were shown and recorded in a computer with sampling time of 100 ms.

Experimental results. We report the results of verification of the proposed model, by taking the result of 10mm bits as an example. The changing trends of torque, penetration rate, friction coefficient, and the specific energy with the increasing of thrust, are shown in Fig.3

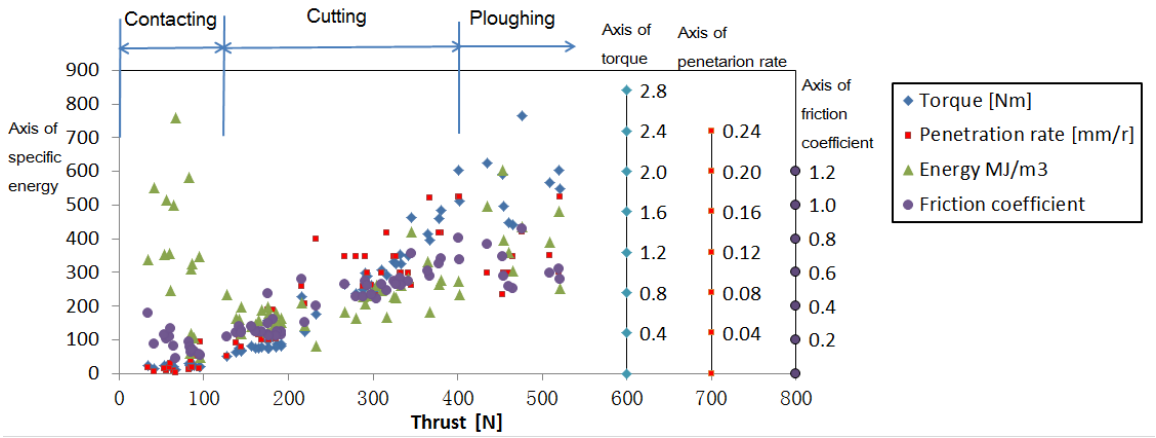

Fig.3 Changing Tendency of the mechanical parameters when the thrust increases

When the thrust changes from 0N to 500N, the torque increases from 0.02Nm to 2Nm. However, the wide-sense friction coefficient is not constant, and it changes in a range of 0.1-0.7. The penetration rate increases with the increasing of the thrust when the thrust is lesser than 400N. When it exceeds 400N, the penetration rate does not increase any more. This penetration thrust is the limit for the drill, bits, and the drilling conditions. The specific energy changes in a low-high-low trend. Above results verified and validated the proposed model.

Conclusions

In this paper, a tri-state theory for drilling processes using diamond impregnated bits was proposed. The relations among some drilling parameters were analyzed. Experiment results verified the correctness of the proposed model and theory.

Keywords: pulsed MIG welding; current waveform control; droplet transfer control

Abstract. The one-droplet-per-pulse transfer is widely considered to ensure the stability of the welding process in pulsed MIG welding; a peak pulse followed by a median pulse in a square wave pulse can effectively enhance droplet transfer controllability and improve weld appearance. The instantaneous current and voltage waveforms, the probability density distributions of current and voltage, and U-I graphs collected by the waveform wavelet analyzer were used to assess the welding quality and weld bead appearance. The 1.2-mm carbon steel welding wire experiments showed that under the same conditions, using a median waveform could significantly improve the welding quality. If the median current was too small or too large, the influence on the welding process was not obvious, and was only representing an increase of the base current or peak current phase. If the median time was too short, the energy accumulated was not enough to control the droplet transfer; conversely, too much median time led to globular droplet transfer. With a backward median current range of 180A-225A and duration range of 8ms-12ms, all experiments resulted in a nice weld effect.

Introduction

The rapid development of electronic and computer technology is making modern welding inverters increasingly intelligent; welding processes using expert systems, neural networks, and fuzzy control methods have achieved some success. For pulsed metal inert gas welding (PMIG), one-droplet-per-pulse transfer is widely considered the best welding process, providing a stable arc voltage, infrequent spatter, and a nice weld. Making a quantitative analysis of droplet transfer is difficult, however, because the process is affected by liquid surface tension, ion current force, gravity, spot pressure, electromagnetic force, as well as welding speed and shielding gas composition and other factors.[1-4] The authors wrote a program to control the output welding current of a self-developed soft switching pulsed MIG welding inverter power based on the DSP2808. Through backward median waveforms experiments, the authors were able to conduct significant research on how current waveform parameters influence droplet transfer.

Characteristics of a Backward Median Waveform

Current strength has an important influence on droplet transfer when the droplet size is small. From the idea of current waveform-controlling droplet transfer, welding researchers have proposed a backward median waveform control method,[5] which is shown in Fig.1. Compared to a single pulse square waveform, a backward waveform adds two parameters: median current, I_m, and median time, t_m. The median phase is designed to enhance droplet transfer controllability. During the welding process, the peak current phase plays the role of droplet growth, the base current phase maintains the stability of the arc burning, and the median phase controls the droplet transfer.

The quality of the welding can be reflected in the stability of the welding process, the amount of splash, arc sound and weld bead appearance, et cetera. Instantaneous current and voltage waveforms can reflect the stability of the welding process; the arc voltage probability density can reflect welding process stability and droplet transfer regularity; the current and UI drawing probability density can show peak energy stability. From the aforementioned methods, we were able to capture the instantaneous current and voltage signals using a Hall sensor and could remove high-frequency interference using wavelet filtering. Then, we studied the optimal parameters of backward median waveform procedure by analyzing the collected data.

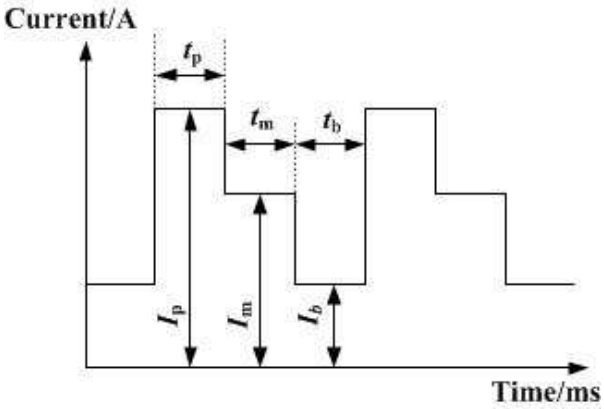

Fig. 1. The backward median waveform

Table 1. Welding experimental data

NO.	Peak current/A	Base current/A	Median current/A	Median time/ms
1	355	82	0	0

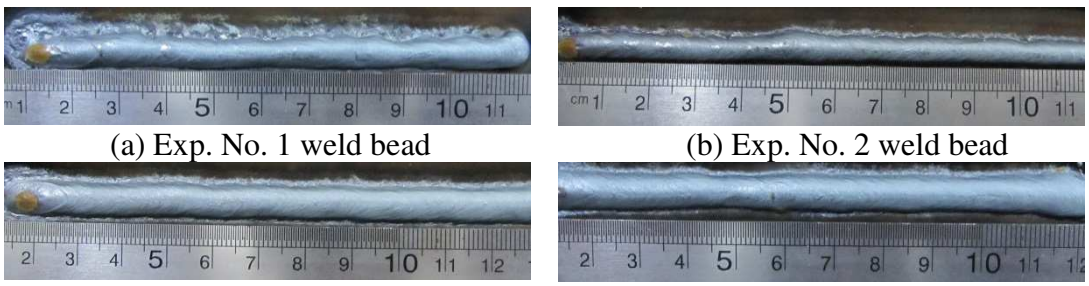
3	355	82	210	8
4	300	65	225	8
5	355	82	210	3
6	355	82	210	12
7	355	82	210	18
8	300	65	180	8
9	300	65	140	8

Experimental Data and Platform

The experimental platform includes the Advantech IPC 610, Advantech PCL1800 signal acquisition card, automatic moving devices, arc dynamic waveform wavelet analyzer, pulsed MIG welding soft switching inverter, and wire feed machine. The experimental conditions are 1.2-mm carbon steel wire, model ER50-6, surface welding on 8mm plate low-carbon steel. The protective gas is 99.99% argon gas with a flowing rate of 17L/min, the wire extension is 18mm, speed of automatic moving devices is 0.35m/min with a constant wire feed speed. Experimental data used as shown in Table 1; the peak current time is 7ms, the base current time is 8ms, and this remained unchanged during the experiment.

Experimental Results Analysis

Effect of the median phase on welding quality. Experiment No. 1 and Experiment No. 2 have no backward median waveform. From comparing these with Experiment No. 3 and Experiment No. 4, we can see a significant difference, as shown in Fig. 2.



(a) Exp. No. 1 weld bead (b) Exp. No. 2 weld bead

(c) Exp. No. 3 weld bead (d) Exp. No. 4 weld bead

Fig. 2. Weld appearance contrast with and without backward median phase

From Fig. 2, we found that Experiments No. 1 and No. 2's weld beads had uneven widths and their welding processes produced "cracking" noises with obvious splashes; Fig.2 (a) had some undercutting. Experiment No.3 and No.4 had nice weld appearances with even, uniform surface ripples, their welding processes were stable, there were no short circuits or breaking arcs, the arcs produced a soft sound, and no splashing occurred.

While analyzing the current and voltage signal acquired, as shown in Fig. 3 and Fig. 4, the arc length was not stable in experiment No. 1; the voltage increased suddenly between 11148ms-11194ms with slight arc breaking. This indicates that the droplet transfer was inconsistent and there was globular transfer behavior. Experiment No. 3's voltage and current waveforms were regular, with a clear droplet transition phase. The process was reproducible and had no short circuits or arc breaking.

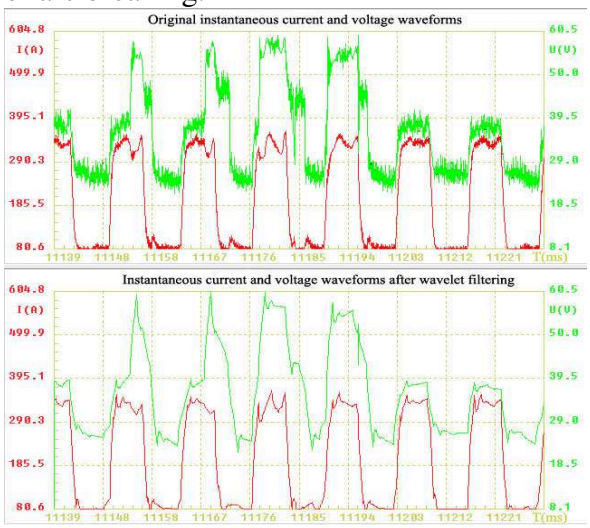


Fig. 3. Exp. No. 1 current and voltage waveforms

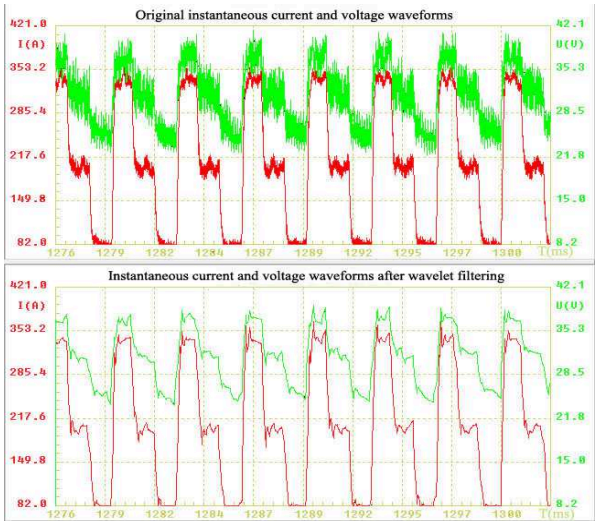

Fig. 4. Exp. No. 3 current and voltage waveforms

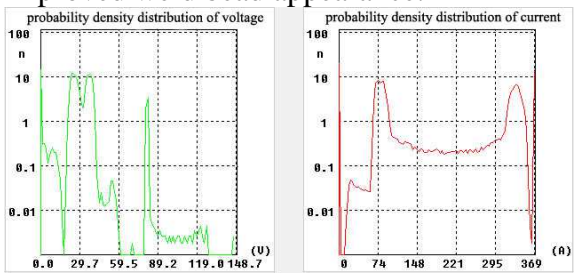
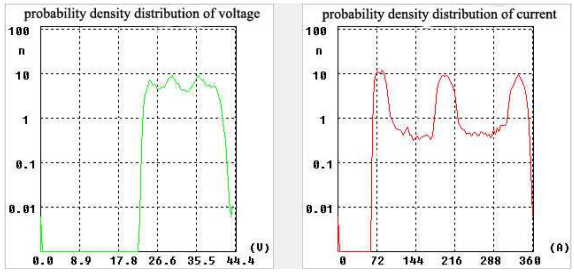
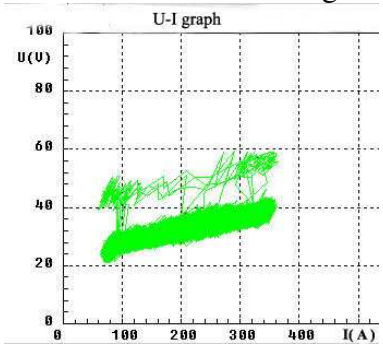
As shown in Fig. 5, Experiment No. 1's voltage signals' probability distribution and U-I graph were more scattered than those found in Experiment No. 3, which indicated that Experiment No. 3's welding process was more stable. In experiment No. 3, droplets were growing during the peak phase; when the current was switched to the median phase, the electromagnetic force made the droplets transfer into a molten pool，so that one-droplet-per-pulse occurred. The droplet transfer process could be controlled by adjusting the parameters of the median current. The experiments detailed above show that backward median currents can effectively control droplet transfer and improved weld bead appearance.



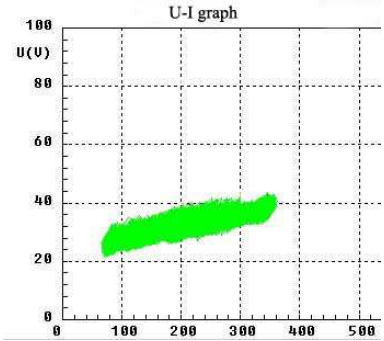
(a) Exp. No. 1 probability density distribution of voltage and current



(b) Exp. No. 3 probability density distribution of voltage and current



(c)Exp. No. 1 U-I graph



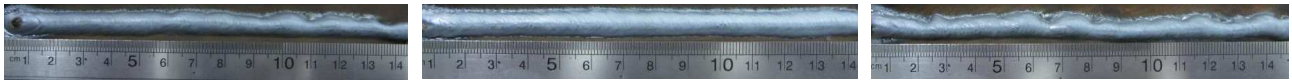
(d) Exp. No. 3 U-I graph

Fig. 5. Signal contrasts with and without backward median phase

Effects of median time on welding quality. As seen in the experiment results shown above, No. 3 had a good weld and a stable welding process. Thus, we set I_m=210A, made t_m different while

keeping other parameters unchanged, and studied the effect of welding when the median time varied.

Fig. 6 showed the weld appearance of different median time, appearance of Fig.6(b) was the best, the weld surface was smooth , surface ripple even and uniform. When t_m was 3ms and t_m was 18ms, the welding process could only be maintained, but the arc sound harsh, splash obvious with short circuit transition behavior, weld width were uneven.



(a) Exp No.5 weld (t_m=3ms) (b) Exp No.6 weld (t_m=12ms) (c) Exp No.7 weld (t_m=18ms)

Fig.6. Weld appearance contrast of different backward median time

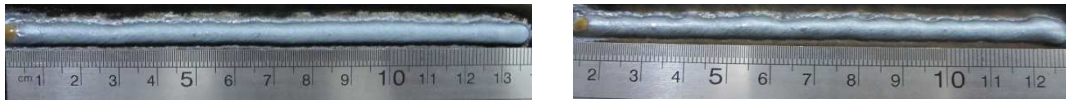
Analyzed weld appearance contrast of different backward median time, when the time was too short, the energy accumulated in median phase was not enough to make droplet transfer, during the next pulse droplet became larger, this led to short circuiting transfer or globular transfer of one-droplet-multi-pulse. In the case of constant wire feed speed, droplet transfer was not regular, so weld width was uneven and welding process was unstable with bad weld bead.

When the median time was appropriate, in the peak phase droplet began to grow up, in the median phase droplet grew up continually with sufficient energy and the electromagnetic force made droplet transfer into molten pool. The welding process was stable and reproducible, arc sound soft, current and voltage waveforms regular, welding quality nice.

When the median time was too long, the median phase energy was large enough to make more than one droplet transferred and grow up, which resulted in droplet transfer irregularities. Droplet transfer happened in peak phase, median phase and base phase, each pulse had varying amounts and sizes of droplets transferred into the molten pool, at this time, arc breaking and short circuit were easy to happen, weld bead as shown in Fig.6 (c).

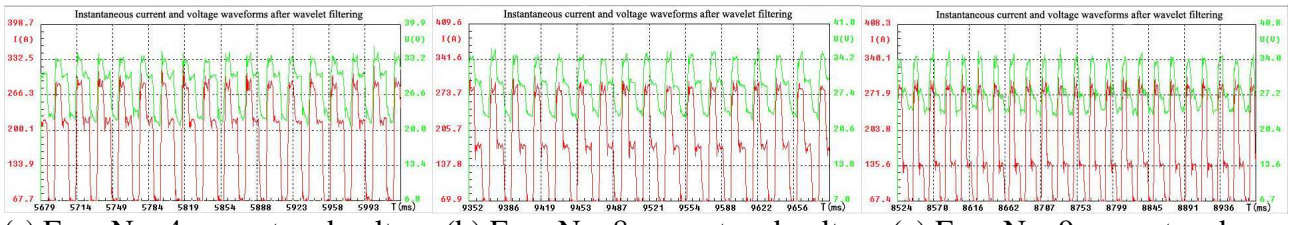
Effect of the median current on welding quality. Based on experiment No.4, we made I_m different while kept other parameters unchanged, studied the effect of welding when median current varied.

From the view of data acquired in experiment No.4, No.8 and No.9, the welding processes were stable when the median current varied from large to small, current and voltage waveforms were regular, no broken arc and short circuit occurred, the arc voice sound soft. As Fig.2(d) and Fig. 7(a) shown, there were smooth weld bead appearance, suitable weld width and penetration and seldom splash when I_m was 225A and I_m was 180A. The welding process was stable but weld appearance began to uneven when I_m was 140A, if it continued to reduce the current, weld effect significantly became worse.



(a) Exp No.8 weld (I_m=180A) (a) Exp No.9 weld (I_m=140A)

Fig.7. Weld appearance contrast of different backward median current



(a) Exp. No. 4 current and voltage waveforms (I_m=225) (b) Exp. No. 8 current and voltage waveforms(I_m=180) (c) Exp. No. 9 current and voltage waveforms(I_m=140)

Fig. 8. Different backward median current and voltage graphs

After analyzing the experimental results, it was found that when the median current was appropriate, droplets were transferred into a molten pool in the median phase, which made the

one-droplet-per-pulse transfer occur. When the median current was small, the accumulated energy was less than the threshold value of the spray transfer. The droplet transfer was not performed at this phase, and the median phase did nothing but allow droplets to grow; the transfer behavior happened at the next pulse through electromagnetic force. If the median current continued to decrease, the median phase would lose effect equivalent to an increase of the base time; this led to a globular transfer multi-pulse with inappropriate peak parameters. The experimental results showed that the value of the median current range was relatively wide, and that welds were better when the median current was more than 140A.

Conclusions

A single pulse followed by a median current waveform could effectively control the droplet transfer process and significantly improve welding quality. The instantaneous current and voltage data acquired from the waveform wavelet analyzer, the U-I graph obtained by analyzing signals, and the voltage and current probability density distribution were effective in the evaluation of the welding process.

The experiments illustrated that the effect of the backwards median time was greater than the current. The welding process was stable and weld bead was better when using 1.2-mm carbon steel welding wire, with the time around 8-12ms and the current between 180A-225A.

Keywords: Oscillation clock, RS 485, MODBUS, PC.

Abstract. In order to greenhouse plants for automatic irrigation operation, was designed based on the soil moisture monitoring system of RS 485 bus system, the oscillation frequency of the clock oscillation circuit, and a main chip count, frequency signal PC software will be the main chip records show, form curve, thus providing the basis of the data for the automatic irrigation, experimentally tested for a long time, the system performance is stable and reliable.

Introduction

In order to be precise on greenhouse soil automatic irrigation operation, monitoring on the need for soil moisture, when monitoring soil moisture did not reach the design threshold start irrigation system requires spray irrigation operation. Soil moisture or humidity is called soil moisture[1], soil moisture is dry and wet soil, the soil water content, available soil moisture percentage of dry soil weight representation. The traditional irrigation mode is the farmer's experience to judge, the artificial irrigation, which will produce the occurrence of irrigation is not timely, irrigation amount of too much or too little, thus affecting the growth of crops. In order to solve this problem, the system research and development of FSD100 soil moisture sensor, and realizes the real-time monitoring of soil moisture with PC software.

The system mainly use RS485 bus to realize the data monitoring soil humidity in the greenhouse, can long distance multi node in soil moisture monitoring greenhouse, and through the monitoring data of graph data, thus for the following automatic soil irrigation to provide information support, through the calibration to perform initial equipment, monitoring tasks can be very good to complete soil humidity, and can be combined with sprinkler irrigation equipment to complete the automatic irrigation operation in the greenhouse. The system mainly includes three parts, one is for the 485 transmission chip for information transmission, the second is the main chip ATTINY13A-SSU, mainly used for frequency counts, the third is the clock oscillation circuit NE555, mainly used for monitoring soil moisture.

The hardware design

The clock oscillator circuit design： Clock oscillation circuit chip is used in this system is NE555, a model in which the chip belongs to the timing of IC 555 series, 555 series IC, pin functions and application are compatible, but the models of different because of the different prices of the oscillation frequency stability, power saving, can produce rate is not the same and the 555 time IC; is a very versatile and widespread, only a few of the resistance and capacitance, can produce a variety of different frequency needed for digital circuit. The system circuit diagram is shown in figure 1.

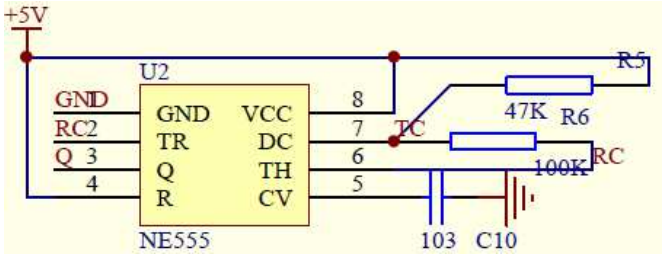

Figure 1. Clock oscillation circuit diagram

Through the combination of NE555 chip resistors and capacitors which clock oscillation circuit simple, by changing the resistance value in the capacitor rated conditions at different oscillating frequencies. The resistance variation of resistance will be accompanied by the change of the soil moisture change.

RS 485 circuit design： In greenhouse humidity monitoring requires a multi node monitoring, namely, a plurality of soil moisture monitoring at the same time, it can be the whole automatic irrigation operation according to the soil moisture in overall greenhouse, multi node communication distance is far, then the signal data using the RS 485 bus for moisture transmission, circuit diagram as shown in Figure 2, the RS 485 is an electrical interface standard, communication interface belongs to the physical layer, there is no uniform communication protocol, but now widely used is the MODBUS protocol, the MODBUS protocol is introduced for.

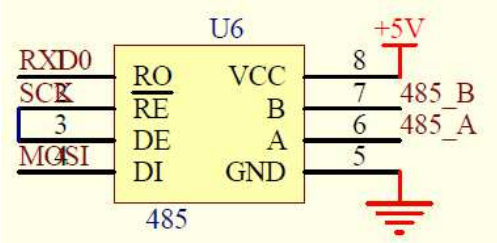

Figure 2. RS 485 circuit diagram

MODBUS was invented in 1979 by Modicon, is the world's first true for bus protocol in industrial field. MODBUS protocol is a common language used in the electronic controller of. Through this agreement, each controller, the controller through the network (such as Ethernet) and other communication devices can be. It has become the industry standard. This protocol defines a controller can use the information to understand the structure, regardless of what they are after the network communication. It describes the process controller requests access to other equipment, how to respond to the request from other equipment, and how to detect errors and records. A common format it set a pattern of information and content domain. When the communication on the MODBUS network, the agreement determines each controller needs to know the device address, recognize the address sent the message, and decide what action. If you need to respond, the controller will generate feedback and issued by the MODBUS protocol. In other networks, including the MODBUS protocol messages into frames or packets used on this network structure. This transformation is extended according to the specific network address, solution section routing path and error detection. The protocol supports the RS-232, RS-422, RS-485 and Ethernet equipment. Many industrial equipment, including PLC, DCS, intelligent instruments are in the use of the MODBUS protocol as the communication standard between them[2].

MODBUS has the following characteristics:

(1) open standard, users can freely, use the MODBUS protocol to safely, do not need to pay a licence fee, does not violate intellectual property rights. At present, support MODBUS manufacturers more than 400, more than 600 kinds of products that support MODBUS.

(2) the MODBUS can support a variety of electrical interfaces, such as RS-232, RS-485 etc, also can be transmitted in a variety of media, such as twisted pair, fiber, wireless.

(3) the MODBUS frame format is simple, compact, easy to understand. The user is easy to use, manufacturers to develop simple.

MODBUS can use RTU or ASCII communication mode, communication in the standard MODBUS. In the configuration of each controller, the user must select the communication of serial port communication mode and parameters. On the MODBUS bus all equipment should adopt the mode of communication and serial communication with the same parameter. Select RTU or ASCII for the MODBUS bus standard, it defines the serial transmission information bus on the meaning of the decision information, packaging and decoding method. The transmission mode used in the project to RTU mode, the following briefly introduced the basic situation of RTU model. The controller in RTU mode on the MODBUS bus communication, information in each of the 8 bits into 2 4 16 hexadecimal characters, the main advantage of this model is its transmission character density is higher than that of ASCII mode in the same baud rate, each information must be continuous transmission.

MODBUS information transmission in frames, each frame has a starting point and end point determination, the receiving device in the beginning of the read address information, and determine to addressing device (broadcast on all equipment, clockwise) and the transmission of information over time, can detect the partial information, false information can also be set as a results. When the communication command is sent to the instrument, with the communication command corresponding address code equipment, and remove the address code, read the information, if there is no error, is to perform their tasks; and then the execution results back to the sender. Send back information including address code, action code, execute the action result data and error checking code. If the error will not send any information.

Address code is the first byte of the information frame (8), from 0 to 255. The byte that host placed in information frame from the machine address code area, and from the machine address. In response, his address in the response information of the address code area, let the host recognition has a response from the machine.

Function code is the information frame to second bytes, 1-225 is a valid code range, when the host to send information from the machine, the function code that should be executed actions to Cong machine. Such as reading a set of register data, read the cluster diagnostic state, when the slave response host, the function code can be explained from the machine normal response or abnormal response, normal, the machine will simply return to the original function of the code, is not normal, returns a code phase equivalent with the original code from the machine, and the most significant bit is set to "1".

The data area includes the need from the machine to execute what action or by the return of information collected from machine. This information can be numerical, reference address etc.. For example, the function code tells the register values from the machine, the data must include the start address register to read and read length. For different from the machine, the address and data information are not the same[3].

MODBUS transmission under RTU mode using parity CRC cyclic code check is redundant, the check code contains 2 bytes, or 16 bits. CRC code from the sending device, tail placed in transmitting information. Receiving information equipment re computing the information received by the CRC code, comparing the calculated CRC code is consistent with the received, if they do not match, then that error. The calculation method of CRC code is, first preset 16 bit register all 1. Then gradually the processing each 8 bit data information. Only in the CRC code for calculating 8 data bits, the start bit and stop bit, such as the parity bit word also comprises the parity bit, do not participate in the calculation of CRC code. In the calculation of CRC code, 8 bit data and register data dissimilarity or, obtained results to the low shift a byte, fill the highest with 0. Check the most low, if the lowest is 1, the register contents and preset number dissimilarity or, if the low of 0, not for xor. This process is repeated 8 times. The eighth shift, the next 8 then and now the contents of register different or, this process is repeated 8 times above. When all the data after the information processing, and finally the contents of register is the CRC code value. Data transmission, CRC codes in the receiving low byte at the front[4].

The main chip circuit design： The main chip used in the design of system is ATTINY13A, the chip is a ATTINY chip produced by ATMEL company integrated with ATMEL's AVR micro controller

and flash memory, including 1KB and 4KB, with 32 KB to 256 KB SRAM. These devices support SPI and TWI communication, provides the high flexibility and the working voltage of 1.8V to 5.5V. ATTINY AVR using ATMEL's patented PicoPower technology, low power consumption. Circuit diagram is shown in Figure 3, the frequency signal in this system is mainly the use of the chip to collect the clock oscillation circuit for counting, and to cooperate with the PC software, generate soil moisture curve, so as to ensure that when soil moisture is lower than a certain value for automatic irrigation operation. Circuit diagram is shown in figure 3.

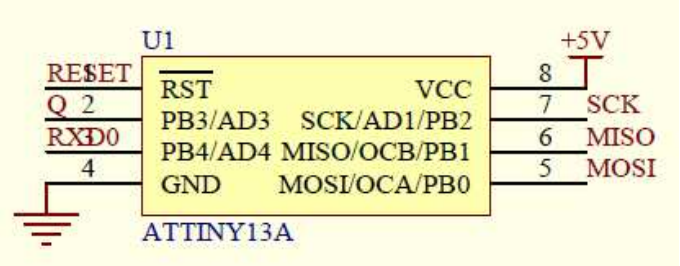

Figure 3. The circuit diagram of the main chip

The PC software design

The sampling system using the oscillating circuit to soil moisture, and the sampling frequency results delivered to the main chip count, the PC has been the main chip to communicate the soil moisture information displayed on the screen, allowing the simultaneous real-time display of the 10 monitoring points in the system design, the test system can monitor 10 use soil moisture conditions, the overall operating normally, curve display effect is obvious, the effect shown in Figure 4 as shown in fig..

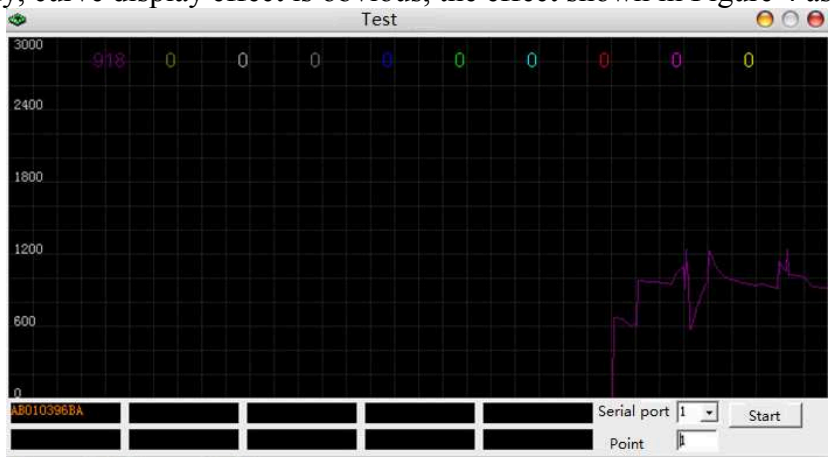

Figure 4. PC software interface

Conclusion

System uses a resistance detection methods of monitoring soil moisture, and the data transmission distance by RS 485 bus interface with PC software, forming the curves of the variation of humidity, automatic irrigation and ultimately for the greenhouse provides data information, through a large number of experiments, the whole system runs normally, for real-time monitoring of soil environmental change, and has a good application prospect and popularization value.

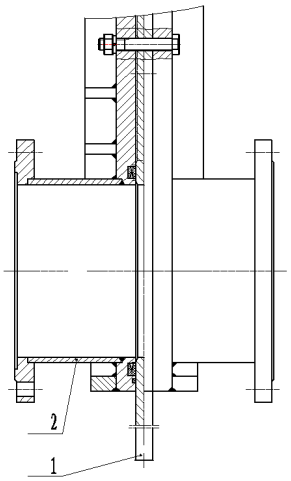
Keywords: Composite Slurry Valve Gate, Large-Diameter, Finite Element Analysis.

Abstract. In a long distance slurry pipeline transport system, pulp valve plays a vital role, which combined the pulp valve application is more, ram is one of the important components of composite slurry valve. This article mainly aims at gate has carried on the design and analysis, finite element modeling, and study the corresponding constraints, in the process of loading method, large diameter combination valve gate stress and strain distribution are obtained, combined with the optimization method and finite element analysis software for its structure optimization research, realize the lightweight of the gate. To reduces the manufacturing cost of the gate, as to provide theoretical basis for design.

Introduction

The slurry valve is one of the important equipment of long distance slurry pipeline transportation. The reliability is an important part of whether the safe operation of the long distance slurry pipeline transport system .Composite slurry valve is used higher on the market now .The valve is a kind of parallel plate type valve [1]. Due to its simple structure, convenient maintenance and disassembly, low cost, long service life, has good abrasion resistance, compression performance. It can realize remote hydraulic control and installation where the operator is not easy to reach. So they are widely used in mines, power plants, metallurgy, chemical industry and other departments of granular material slurry transportation, especially on high pressure slurry in pipeline, is the ideal replacement valve.For a long time, because the problems of bending stiffness caused by valve disc in the elastic deformation are failed to properly solve. To make the problems of valves jammed in the valve gate existing during the work.



1- gate 2- composed of valve body

Fig. 1 Diagrammatic Sketch of Composite Slurry Valve

Gate is still lack of detailed theoretical analysis on the design, some formulas and coefficients of reference which have used are not accurate enough or hard to search, resulting in widely use in the design of flexible disc analogy method and the inheritance law, and then the accuracy and repeatability of the calculated value is lost relatively[2] .This article makes a deep research and analysis on the problem, the stress calculation, found out the theories of solutions to gate elastic deformation , put forward the feasible measures to solve this problem.

The large diameter combination slurry valve structure

Composite slurry valve is a kind of parallel plate gate valve (Fig. 1). When the valve opens, gate rise to match it's holes to a seat hole, equal to the outer pipe diameter, constitute a spool valve. When the valve is closed, gate fell and brake channel to death. Between gate and seat placed polyurethane seals and support ring, support ring also plays a role of sealing, so it is double seal. So no matter open or close the valve, sealing performance is good.

Due to the combined pulp valve is the off-standard valve gate, no molding formula can be drawn lessons from the process of gate design. The design of the blindness still exists, conventional design methods led to too thick gate problem. Aimed at the problem this article chooses the following two sets of formula design of comparison, the selected gate size 600 mm, nominal pressure of 4Mpa, The structure of gate is shown in Figure 2.

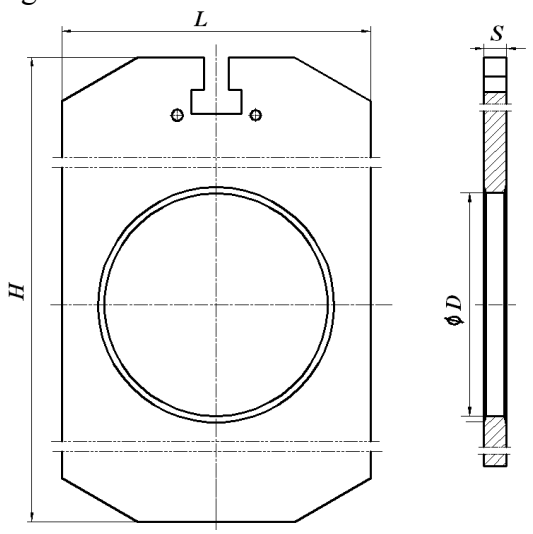


Fig. 2 The Structure of Gate

The traditional gate thickness design formula is:

$$S = 0.55 D_{MP} \sqrt{\frac{P}{[\sigma]}} + C \tag{1}$$

Where，S is thickness of the gate, unit: mm.

D_{MP} is the average diameter of sealing surface , unit: mm.

P is the pressure, the unit: Mpa.

$[\sigma]$ is allowable bending stress of material, unit: Mpa.

C is the design margin, unit: mm.

According to the actual engineering situation, this design gate choose materials for 45 # steel.The allowable bending stress is 135 Mpa. The nominal pressure is 4 Mpa. The design margin is 2 ～ 3 mm, The average diameter of sealing surface is 740 mm.Above the known parameters in formula (1) was calculated and the gate thickness for 75 mm.

The finite element analysis of gate

There are many finite element analysis software now .Such as ANSYS, DYNA3D, NASTRAN, ABAQUS, ADINA, and AFEMS. In this article ANSYS finite element software is used. Because gate

model structure is simple, first of all, used Sold Works software modeling, and then passed to the ANSYS finite element software to make a proper modification analysis, generated finite element model, in ANSYS static analysis. Gate materials are stainless steel 45 # steel, gate main dimensions and material properties such as table 1.

Table 1 The main dimensions and material properties of gate

Projects	Value	Unit
Thickness of the gate(S)	75	mm
Total Length of the gate (L)	820	mm
Total Height of the gate(H)	2140	mm
Hole diameter in the gate(D)	600	mm
Gate total weight(Wg)	812	kg
allowable bending stress of material ($[\sigma]$)	135	Mpa
Density	7850	Kg/m^3
The Elastic Modulus (E)	2.06×10^5	Mpa
Poisson's Ratio (u)	0.3	

Gate simplified for ax symmetric structures from the geometric shapes, gate force has the following three states.

1) When the valve is in open state, gate in a double sealed a medium in the pipe.

2) When the valve is closed, the gate in a single seal, valve side have medium.

3) The valve is in a state of half closed, gate double medium, gate in a state of balance.

In the three states stress, gate in the first kind of circumstance condition, namely single seal were the biggest load. Therefore load on the finite element analysis.

According to the actual working status of the valve, and its constraints mainly through the gate between the sealing plate and support for fixed, therefore, carried out on the contact surface between gate and seal plate displacement constraints. The load and supports of analysis setting is as shown in figure 3.

Because gate model structure is simple, the whole structure with eight nodes hexahedron element meshing.The meshing model is as shown in figure 4 .

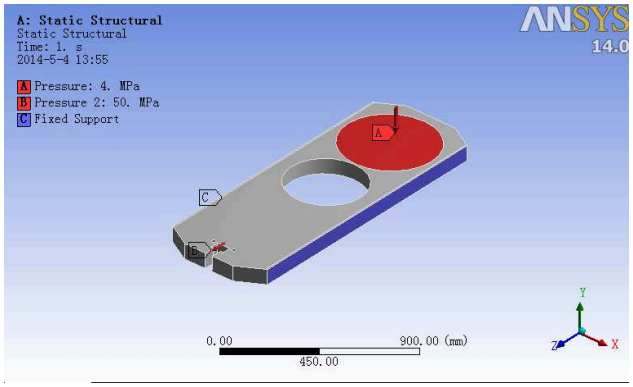

Fig. 3 Load and Supports of the Gate

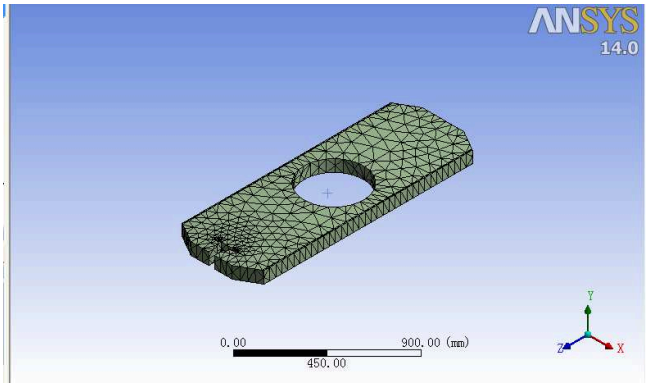

Fig.4 Finite Element Model of the Gate

The purpose of finite element analysis is obtained the response of the mechanics basic variables under a certain load, such as stress, displacement and elastic strain. Discussed the deformation, stress and elastic strain condition after the gate under external force action .According to the actual working status of the valve, and its constraints, mainly through the gate between the sealing plates and support for fixed, therefore, carried out on the contact surface between disc and seal plate displacement.

Due to the main load bearing of gate is the sealing surface of slurry nominal pressure, therefore, this article on the damper applied load: Role in the seal surface of 4 MPa nominal pressure. After the calculated by finite element analysis, get the contour plot of gate stress distribution (figure 5), the contour plot of gate displacement distribution (figure 6), and the contour plot of gate strain

distribution (figure 7).To see from the picture, the area of gate stress concentration distribution in the pipeline on both sides of the seal plate support, gate maximum bending deformation occurred in the location of the contact with the pipe size, this result in conformity with the actual.

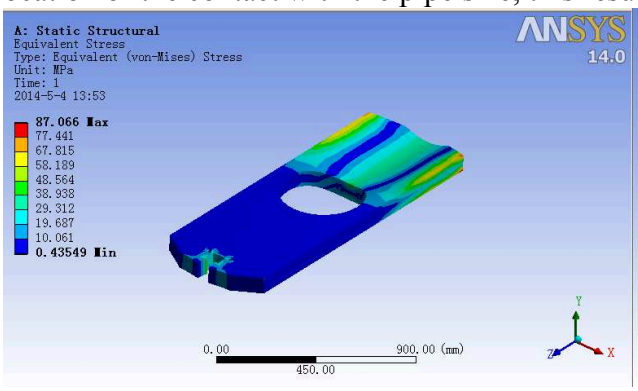

Fig. 5 The Contour Plot of Stress Distribution of Gate

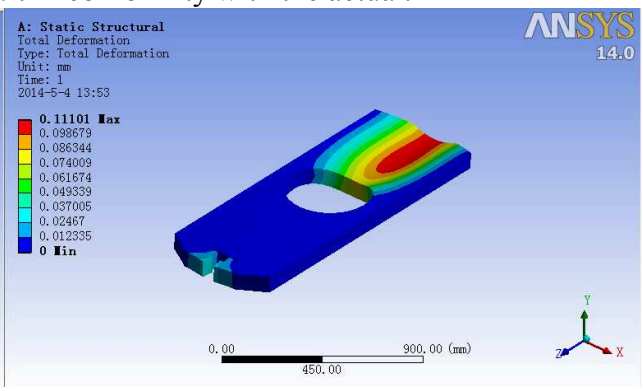

Fig. 6 The Contour Plot of the Gate Displacement Distribution

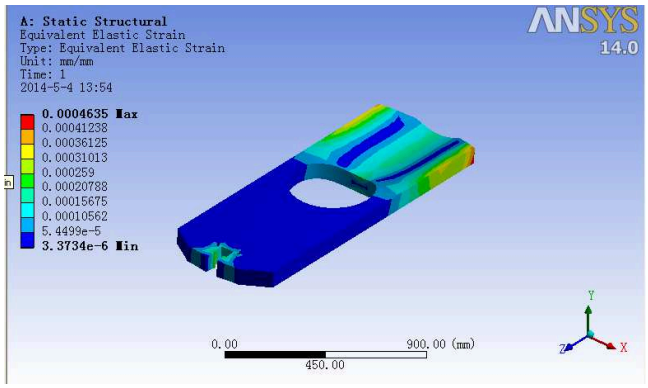

Fig. 7 The Contour Plot of the Gate Strain Distribution

Conclusion

This article introduced the structure design of gate, and Sold Works software for 3D entity modeling, and then conducted on the physical model of reasonable simplification, select the unit type finite element analysis, meshing, set up the finite element model of the gate, after applying constraints and loads, the static model, according to the result of model calculation, to analyze the structural strength and stiffness of the gate is verified. Finite element analysis show that the stress concentration area of composite slurry valve gate distribution in the sealing plate on both sides of the support of the contact with the pipe, gate maximum bending deformation occurred in contact with the pipe size of the circle domain.

Key words: Fit degree, Aircraft part, Assembly process, Economical manufacturing.

Abstract: Aircraft manufacturing process normally requires very high precision assembly parts which are achieved in practice by a high-precision machining parts followed by a high coordination degree assembly process. The current practice in aircraft parts manufacturing process is that the manufacturing cycle is long, the rework rate is high and the manufacturing precision is difficult to improve. This can be sometimes infeasible or very costly. In this paper, we consider a fit degree calculation method to achieve precision aircraft parts with economical manufacturing processes. We consider an analytical approach to establish a physical process model to guide the design and machining process of assembly parts, which can assume the fit degree. The results show that the approach can obtain the nearly optimal process parameters at designated fit degree. At last, a case is developed to verify the proposed methods.

Introduction

An aircraft is known as a kind of transportation which has complex product composition, complex product technologies, complex manufacturing processes, and complex project management, complex mechantronics equipment, micro-sensors etc. In the process of design and manufacture of an aircraft, it is very important that part tolerance is practically designed to meet the requirements of aircraft's quality, performance, machining, assembly, manufacture, cost, and so on [1]. Currently practice for the manufacturing process of the aircraft parts is to control each part machining process of the assembly parts respectively. Although this independent control method could be an effective selection of improving aircraft manufacturing precision and fit degree of final product assembly process, its cost will be considerably high to achieve a desired fit degree. Therefore, this paper will develop an effective fit degree calculation method with fully utilizing the quality information of the overall aircraft parts manufacturing process and the relationship between the two assembly parts. In the past study, Kannan and Jayabalan [2] proposed a grouping method for a complex assembly with three mating parts. Kumar and Kannan [3] proposed a method using a genetic algorithm for obtaining optimum manufacturing tolerance to reduce the number of surplus components and manufacturing cost. Asha et al. [4] proposed a method for finding the best combination of components with multiple quality characteristics to minimize clearance variation. Matsuura and Shinozaki [5] derived an optimal manufacturing mean design that minimizes the number of surplus mating parts. Kannan et al. [6] proposed a method for obtaining the best combination of components under Taguchi's loss function.

Manufacture parameters of aircraft parts for Fit degree calculation

The manufacturing parameters of aircraft parts for fit degree calculation have been provided. In this framework, each key phase parameters of manufacturing process is embodied by a functional component. Fig. 1 shows an overview of the fit degree calculation method proposed in this paper.

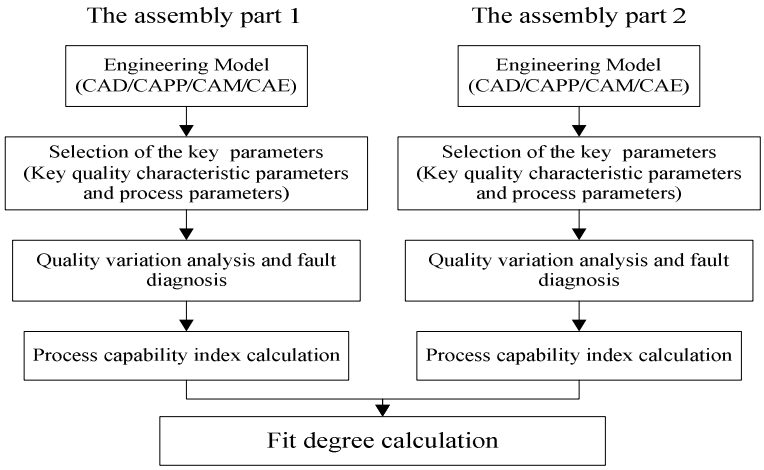

Fig.1. Fit degree calculation framework of aircraft parts manufacturing process

In this fit degree calculation method, each component has its specific functionality. The manufacturing parameters of aircraft parts are provided by each key manufacturing process. After the required manufacturing information is obtained, we can calculate the fit degree of two mating aircraft parts. The fit degree in aircraft parts assembly is defined as the ratio of suitable mating parts assembled to those manufactured including defective parts, which means the percentage of two matched parts that can be paired off. Fit degree can be calculated through the PCI of two mating parts, which indicates how well the predicted result fits within the specification limits. This component is able to support the evaluation and improvement of the aircraft parts manufacturing process. If the quantitative fit degree value of mating parts can be calculated, certain precautions or quantitative quality feedback on how to adjust manufacturing process or parameters can be taken to reduce surplus parts, thus, guarantying the desired fit between mating parts and increasing the effectiveness of the aircraft parts manufacturing process.

Fit degree calculation

In an aircraft part manufacturing process, the machining process is a controllable and adjustable multistage process, so the quality data often fit the curves represented by a mathematically derived normal distribution curve. Therefore, the normal distribution is adopted in the analysis although the fit degree calculation method.

From aircraft parts manufacturing process, we can get the overall process capability index C_{pm}:

$$C_{pm} = \frac{USL - LSL}{6\sqrt{E(X-T)^2}} = \frac{USL - LSL}{6\sqrt{E(X-\mu+\mu-T)^2}} = \frac{USL - LSL}{6\sqrt{E[(X-\mu)^2 + (\mu-T)^2 - 2(X-\mu)(\mu-T)]}}$$

$$= \frac{USL-LSL}{6\sqrt{E(X-\mu)^2+(\mu-T)^2-2E(X-\mu)(\mu-T)}} = \frac{USL-LSL}{6\sqrt{\sigma^2+(\mu-T)^2-2(\mu-T)(\mu-\mu)}} = \frac{USL-LSL}{6\sqrt{\sigma^2+(\mu-T)^2}} \quad (1)$$

Let P_d represent the percent defective of process output, P_y and P_d are all the functions of two variables C_{pm} and k, where k is defined as the ratio of the bias of process mean to its target (Kane[7]). The two process quality indexes in terms of C_{pm} and k are shown as follows:

$$P_y = \Phi\left[3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}(1-k)\right] - \Phi\left[-3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}(1+k)\right] \quad (2)$$

$$P_d = 1 - \Phi\left[3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}(1-k)\right] + \Phi\left[-3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}(1+k)\right] \quad (3)$$

The estimated percentage of dimensions falling into each selective group *i* can be expressed as:

$$\begin{aligned} P_i &= P\left[\left(USL - i\frac{USL-LSL}{t}\right) < x \le \left(USL - (i-1)\frac{USL-LSL}{t}\right)\right] \\ &= P\left[3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}\left(1-k-2\frac{i}{t}\right) < Z \le 3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}\left(1-k-2\frac{i-1}{t}\right)\right] \\ &= \Phi\left[3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}\left(1-k-2\frac{i-1}{t}\right)\right] - \Phi\left[3\frac{C_{pm}}{\sqrt{1-9k^2C_{pm}^2}}\left(1-k-2\frac{i}{t}\right)\right] \end{aligned}$$

i=1,2,…,t (4)

The fit degree in the aircraft parts assembly process is defined as the ratio of mating parts assembled to those manufactured parts. The fit degree of two mating parts P_{md}, which is,

$$P_{md} = \sum_{i=1}^{t} \min[P_{fi}, P_{mi}] \quad (5)$$

$$P_{md} = \sum_{i=1}^{t} \min\left\{\begin{array}{l}\left\{\Phi\left[3\frac{C_{pmf}}{\sqrt{1-9k_f^2C_{pmf}^2}}\left(1-k_f-2\frac{i-1}{t}\right)\right] - \Phi\left[3\frac{C_{pmf}}{\sqrt{1-9k_f^2C_{pmf}^2}}\left(1-k_f-2\frac{i}{t}\right)\right]\right\}, \\ \left\{\Phi\left[3\frac{C_{pmm}}{\sqrt{1-9k_m^2C_{pmm}^2}}\left(1-k_m-2\frac{i-1}{t}\right)\right] - \Phi\left[3\frac{C_{pmm}}{\sqrt{1-9k_m^2C_{pmm}^2}}\left(1-k_m-2\frac{i}{t}\right)\right]\right\}\end{array}\right\} \quad (6)$$

Equation (6) means that, we can get C_{pmf}, C_{pmm}, and k_f and k_m from the aircraft parts manufacturing process, the fit degree P_{md} in the aircraft parts manufacturing process can be calculated.

Example

The following example is presented to illustrate the performance of the developed fit degree calculation method of aircraft parts manufacturing process. The process of a cylinder and piston (as shown in Fig. 2) assembly, which is used in a kind of aircraft engine, provides an example of high precision pair of mating parts. The fit of cylinder and piston is a clearance fit in this case study and high accuracy of this pair of assembly parts is essential, because there is a target value for the clearance. High precision machining and match assembly are usually adopted for these aircraft parts manufacturing process, the allowable minimum clearance is 0.01 mm, and the allowable maximum clearance is 0.02mm. The manufacturing specifications for the mating parts are as the follows.

Table 1 Quality specification and machining process of cylinder

Stage No	Stage name	Content of stage and its quality characteristic (mm)
1	Milling	Mill locating surface---the bottom side of cylinder block and the flatness of it is less than 0.01mm, need to ensure the distance between this surface and machining datum surface.
2	Clamping	Clamp the machined locating surface and the flatness of the surface is less than 0.02.
3	Boring	Bore the inner diameter of cylinder to $\emptyset 150.12_{0}^{+0.034}$
4	Grinding	Grind the inner diameter of cylinder to $\emptyset 150_{0}^{+0.018}$

Table 2 Quality specification and machining process of piston

Stage No	Stage name	Content of stage and its quality characteristic (mm)
1	Milling	Mill locating surface---the bottom side of piston and the flatness of it is less than 0.01mm
2	Rough turning	Mill the external diameter of piston to $\emptyset 150.2_{-0.01}^{+0.024}$
3	Finish turning	Mill the external diameter of piston to $\emptyset 150_{-0.009}^{+0.009}$

By Tables 1 and 2, the machining process of the two mating parts includes three stages respectively, in which the inner diameter dimension of cylinder and external diameter dimension of piston are the key quality attributes to be satisfied.

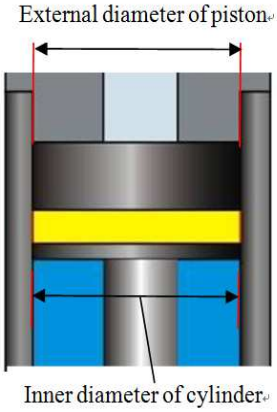

Fig. 2 A cylinder and piston assembly

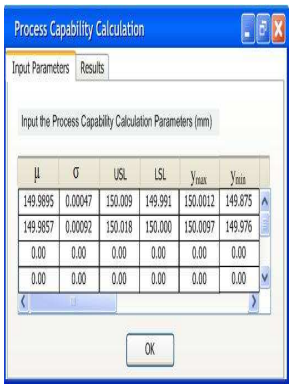

Fig. 3 Process capability calculation parameters inputting

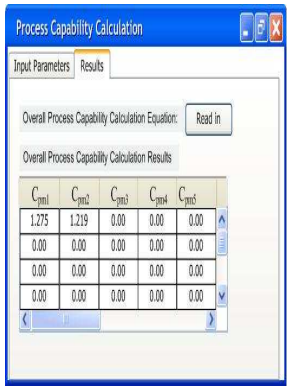

Fig. 4 Process capability calculation results

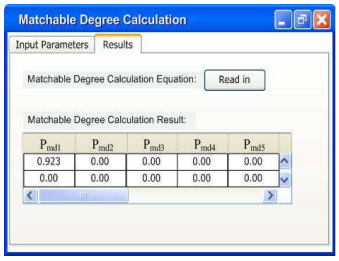

Fig. 5 Fit degree calculation results

After the overall process capability indexes C_{pm} of the two mating parts were obtained (as shown in Fig. 3 and 4), the results were sent to the fit degree calculation. The calculation output is shown in Fig. 5. This aircraft part manufacturing process is acceptable, as its P_{md} is 0.923.

Conclusion

As the fit degree of an aircraft part manufacturing process can be calculated, the complex product design and manufacturing processes could be adjusted in time to reduce the cost. In this sense, the fit degree calculation method as presented in this paper can be adopted to reduce the unnecessary loss of manufacturing cost and time.

Fuzzy adaptive PID controller optimization design in temperature control system

Xiaopeng Li[a], Lanzhen Chen[b, *]

Information engineering institute of Gannan Medical University，Ganzhou 341000，China

[a]happyday-007@163.com, [b]danrou_2006@qq.com

Keywords：fuzzy control；PID control；Smith predictor

Abstract：A new self-adjusting PID controller based fuzzy inferences is proposed. Using fuzzy inferences method, the PID parameters can be adjusted adaptively online for the varying state of the system. This approach has more significant performance and robustness than conventional PID contorllers in any conditions. Traditional fuzzy control systems have difficulties for plants with great delay．A fuzzy PID system based on the Smith compensation theorem is proposed in the paper．It allows to change the transfer function of the plant．Simulation results are also given．

1.Introduction

In the study of Biomedical Engineering, the requirements on temperature are very strict. The traditional temperature control system generally adopts PID control algorithm. However, in the temperature control process which using this algorithm, often encounter delay, and the existence of time delay affects the stability of the system seriously, cause the system overshoot becoming big, the adjusting time becomes longer, even oscillation, divergence, which makes the dynamic quality of the system greatly decreased. If you still use the conventional PID controller, it is hard to tune the PID parameters. Aiming at this problem, this paper designs an improved self-adaptive fuzzy PID controller, which has the advantages of fuzzy control is flexible, adaptable, and has high precision of PID control, self-tuning function online and can realize the PID parameter and reduce the impact of time delay.

2.The traditional PID control

The control algorithm of the conventional PID controller is as follow:

$$u(t) = K_P e(t) + K_I \int_0^t e(t)dt + K_D de(t)/dt$$

Consider of the stability of the system, the speed of response, overshoot and steady-state accuracy into account, the roles of KP, KI, KD are as follows:

(1)The role of proportional coefficient (KP) of is to accelerate the response speed of the system, improve the system control accuracy.

(2)The function of integral action coefficient (KI) is to eliminate the steady-state error of the system.

(3)The role of differential coefficient (KD) is to improve the system dynamic characteristics, its main function is to change in response to inhibition of deviation in any direction, the deviation changes were predicted in advance.

3. The optimal design of the fuzzy adaptive PID control

Based on the traditional fuzzy adaptive PID controller, the optimized fuzzy adaptive controller added a Smith predictor; the controller error E and error rate of change of EC as input, which can meet the different moments of E and EC on PID parameters self-tuning requirements. The structure of the controller as shown in Figure 1:

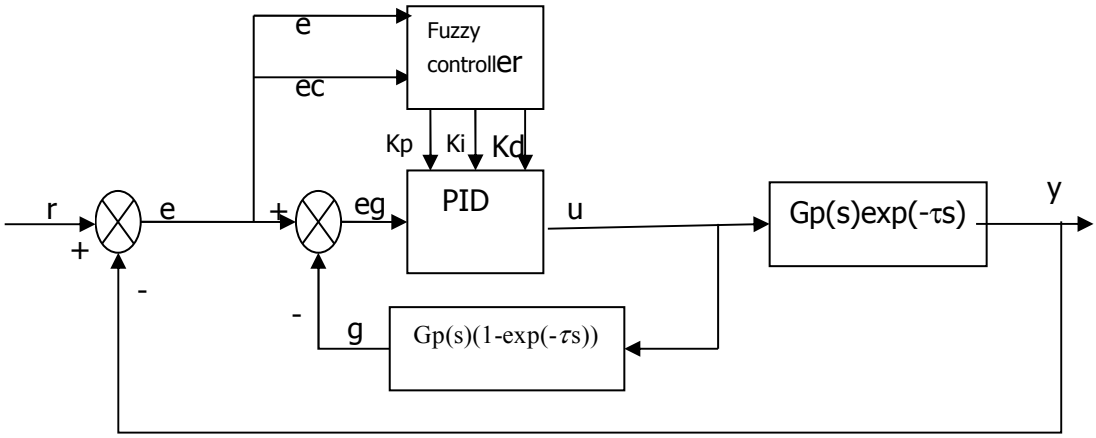

Fig. 1 Fuzzy adaptive PID controller schematic

The key of PID parameters fuzzy self setting is to find the three PID parameters KP, KI, fuzzy relation between KD and E and EC, through the continuous detection of E and EC in the operation, according to the fuzzy control principle to achieve the KP, KI, modify the KD online, which meet the needs of different e and EC to control parameters of the request, the object has good dynamic and static performance.

3.1 The fuzzy language variables and the determination of their membership functions

Set the input temperature fuzzy controller E and temperature change rate of EC, the fuzzy treatment to obtain the fuzzy linguistic variables E and EC, the fuzzy subset of E and EC are {NL, NM, NS, ZO, PS, PM, PL}, the same output KP, KI, fuzzy subset of KD were {NL, NM, NS, ZO, PS, PM, PL}, selection of fuzzy language variables E and EC as well as KP, KI, domain KD were {-6, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 6}, and let E and EC obey the triangle membership function curve, KP, KI, KD obey Gauss membership function curve, in order to obtain good steady-state performance, the input variable of E were irregular division, at the temperature E is zero in the vicinity of a high sensitivity, guarantee the steady state system to achieve higher control precision.

3.2 Establish control rule table

Fuzzy adaptive PID is performed by calculating the fuzzy inference system error E and error change rate of EC, using the fuzzy rules for the fuzzy reasoning, and inquiring fuzzy matrix table to parameter adjustment. The core of fuzzy control design is the use of technology to support engineering staff knowledge and practical experience, taking into account the role of the relationship between the three parameters at different times and with each other, through repeated experiment adjustment to get the fuzzy control rule table which according to three parameters self-tuning:

Parameters 1

ΔK_p ec / e	NL	NM	NS	ZO	PS	PM	PL
NL	PL	PL	PM	PM	PS	ZO	ZO
NM	PL	PL	PM	PS	PS	ZO	NS
NS	PM	PM	PM	PS	ZO	NS	NS
ZO	PM	PM	PS	ZO	NS	NM	NM
PS	PS	PS	ZO	NS	NS	NM	NM
PM	PS	ZO	NS	NM	NM	NM	NL
PL	ZO	ZO	NM	NM	NM	NL	NL

Parameters 2

ΔK_I ec / e	NL	NM	NS	ZO	PS	PM	PL
NL	NL	NL	NM	NM	NS	ZO	ZO
NM	NL	NL	NM	NS	NS	ZO	ZO
NS	NL	NM	NS	NS	ZO	PS	PS
ZO	NM	NM	NS	ZO	PS	PS	PS
PS	NM	NS	ZO	PS	PS	PM	PL
PM	ZO	ZO	PS	PS	PM	PM	PL
PL	ZO	ZO	PS	PM	PM	PL	PL

Parameters 3

ΔK_D ec / e	NL	NM	NS	ZO	PS	PM	PL
NL	PS	NS	NL	NL	NL	NM	PS
NM	PS	NS	NL	NM	NM	NS	ZO
NS	ZO	NS	NM	NM	NS	NS	ZO
ZO	ZO	NS	NS	NS	NS	NS	ZO
PS	ZO	ZO	ZO	ZO	ZO	ZO	ZO
PM	PL	NS	PS	PS	PS	PS	PL
PL	PL	PM	PM	PM	PS	PS	PL

3.3 The fuzzy reasoning which based on the fuzzy rule table

According to the fuzzy control rules table 1 ~ 3, 49 control rules can be obtained:

(1) If (e is NL) and (ec is NL) then (K_P is PL) (K_I is NL) (K_D is PS)

(2) If (e is NL) and (ec is NM) then (K_P is PL) (K_I is NL) (K_D is NS)

……

(49) If (e is PL) and (ec is PL) then (K_P is NL) (K_I is PL) (K_D is PL)

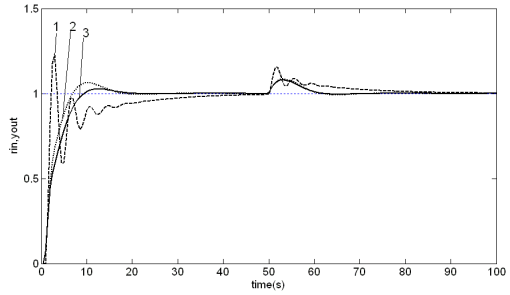
According to the fuzzy membership function of the fuzzy subset assignment table and the parameters of the control model, the application of fuzzy reasoning of fuzzy matrix synthesis of the design parameters of PID, the online correction of PID parameters, the calculation formula is as follows:

$K_P=K_P'+\Delta K_P$

$K_I=K_I'+\Delta K_I$

$K_D=K_D'+\Delta K_D$

4.The results of simulation



From the above step response curve can be seen, with the traditional PID control and fuzzy adaptive PID control is compared, the optimized fuzzy PID response curve of the most superiority, its fast response, small overshoot, and robustness is high, which is combined with the traditional PID control and fuzzy adaptive PID control's advantages at the same time, by adding a Smith predictor, eliminates the detrimental effect of time delay in temperature control system.

Keywords: Particle filter; Regeneration opportunity; Pressure drop

Abstract. The accurate diagnose of the timing of regeneration is the key factor of solving the problem that the filter body is damaged and the process of regeneration is uncomplete. The timing of regeneration judged by the exhaust back pressure is a type of widely accepted control method, the essence of which means to estimate whether the quantity of particle in the filter can fulfil the demand of regeneration or not. In the process of practical application, this kind of method is influenced by the engine conditions, therefore, we must monitor the engine at any moment by speed and load of signal acquisition.In this article,it summarizes two dimensional pulse spectrum" exhaust flow--pressure drop" through universal characteristics test. Meanwhile it conducts the temperature correction in order to simplify the complexity of the judge-ment of regeneration opportunity.

Introduction

The Diesel engines has been developed and introduced in the transportation and other fields,with the benefits of better fuel economy and higher thermal efficiency.However,with the deteriotation of global environment and the strictness of emission regulations,the emission of diesel engines has drawn widely attention from the world.The mainly harmful emissions of the diesel engines are NO_X and particulate. The amount of particulates released by the diesel engines is about 30-80 times of the amount of the gasoline engine[2].Diesel particulate filter is the one of the major aftertreatment technologies to meet airpollution environment regulation,because of higher capture efficiency,up to 90%.Two major points,namely capture and regeneration,have been repeatedly taken into consideration.The accurate diagnose of the timing of regeneration is determined by the amount of the particle which are deposited on the filter.Not only can the deposition of the particulate lead to the rising of the back pressure but affect the ability of the engine and the regeneration process[3].Nowdays,the determination of the regeneration opportunity is based the three priciples:(1)the rising of back pressure caused by the deposition of the particulate in the filter;(2)the effect of the amount of the deposition in the filter for the regeneration process;(3)the relation between regeneration energy consumption and regeneration effieciency[4].The regeneration opportunity judged by the exhaust back pressure is a type of widely accepted control method,this method is not only influenced by the engine conditions but the amount of deposition. There are still relatively larger errors ,including the change complexity of the engine load and dramatic change in the flow rate of the exhaust[5].In this article,it summarize two dimensional pulse spectrum"exhaust flow--pressure drop"through universal characteristics and the temperature correction to simplify the control method ,depending on the control strategy of back pressure and giving up traditional three dimensional pulse spectrum"speed-load-pressure drop".

Experiment equipment

Test engine is a 4-cylinder diesel engine to meet stage V emission regulation, and its related technical parameters are listed in Table 1.

Table 1 The basic parameters of engine GW4D20-V

Displacement (L)	2.0
Rating power/speed kW/ (r/min))	110/4000
Maximum power/speed (N·m/(r/min))	320/1800-2800
Low fuel consumption (g/kW·h)	205
Emission standard	stage V emission regulation
Fuel systerm	electronically controlled high-pressure common rail
Aftertreatment system	DOC＋DPF

Engine universal characteristics test

In order to obtain the original datas,including the original engine exhaust soot, DOC outlet temperature and the exhaust flow ,the experiment system contains the aftertreatment only with the installation DPC and without the installation of DPF, and operats on this woking conditions that speed ranges from 1000 ~ 4000r/min, rising in the order of 200r/min, each of which corresponds to six different throttle opening, including the engine idling condition.the universal characteristic tests can be achieved by these engine operating conditions. Using EEPS-3090 measures levels of particulate matter in the exhaust;and thermocouple temperature sensors were installed in the DOC inlet and outlet to do temperature measurements.

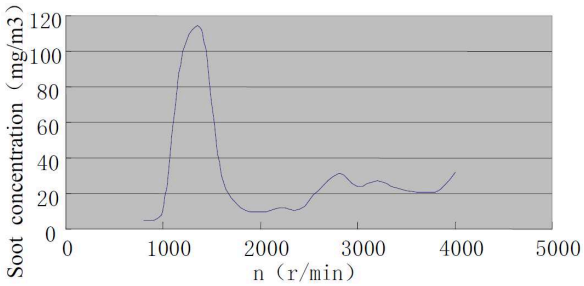

Fig. 1 The soot distribution of engine universal characristics

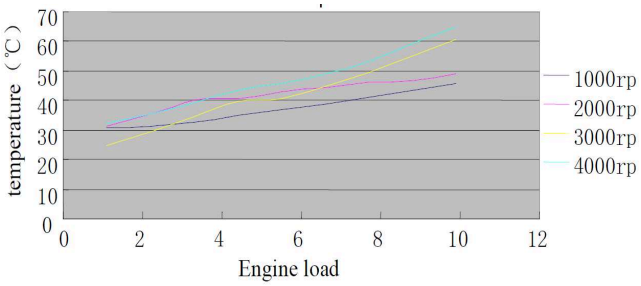

Fig. 2 DOC inlet temperature of the universal characteristics

As shown in Figure 1, the distribution of soot concentration of the engine at the full load. It can be observed from the figure that as the the engine speed ranges from 1000r/min to 1800r/min , soot concentration rised first and then declined ,in the process ,the soot concentration get to the peak,about 110mg/m3, at the full load and the speed of 1400r/min. In the range from 1800r/min to 2400r/min , soot emission concentration is relatively lower overall average concentration about 11.2mg / m3. After 2400r/min, the concentration of soot emissions is more than 20 mg/m3, but overall remain lower. In summary, the engine has a large amount of soot emissions when at low speed and full load; It is relatively lower concentrations of soot emission at high-speed and large load. Figure 1 shows the general characteristics of this engine soot emission at the full load, but also provide a reference for choice to the working conditions of the following pressure drop characteristics and soot load test.

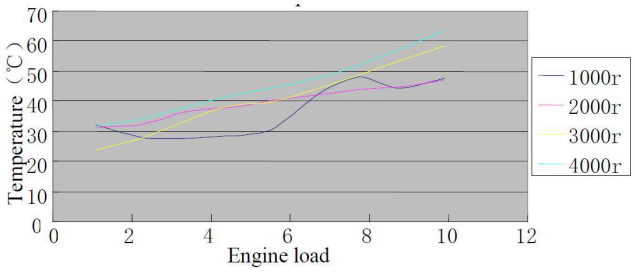

Fig. 3 DPF inlet temperature of the universal characteristics

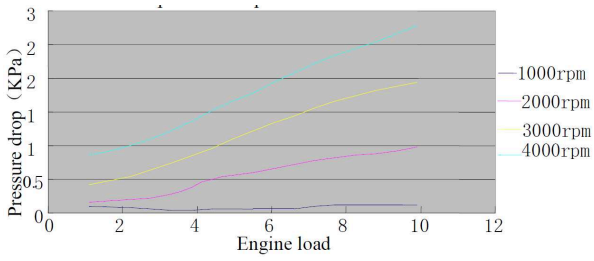

Fig. 4 The pressure drop of DPF in universal characteristic conditions

Figures 2 and 3 are respectively the change of the DOC inlet temperature and the DPF inlet temperature at the full load. From the figure we can clearly see the DOC and DPF inlet temperature distribution under different conditions. Exhaust temperature of diesel cars are overall lower and as seen from the figure, there is rarely working conditions that exhaust temperature can exceed 600 ℃ and almost in full speed and full load . To ensure a smooth DPF regeneration, DPF inlet temperature needs to be maintained at about 600 ℃, but it's difficult for the vehicle in the normal condition to meet this requirement, which requires additional measurements to address this problem. Figures 2 and 3 help choose the working conditions for the following pressure drop test and regeneration.

DPF pressure drop test

The universal characteristics of fresh DPF. For the fresh DPF,when the DPF carrier has certain physical parameters without any soot loading, pressure drop depends only on the engine exhaust. In the detailed testing process of this part,ensure that the DPF soot loading is below 5%. During the test,block EGR tube so that EGR does not work to restrict high soot emissions at certain conditions. Figure 4 shows fresh DPF pre-ssure drop distribution at a universal characteristic condition . Because when DPF pressure drop depends on the volume flow of the exhaust gas, the higher the gas temperature, mass flow rate will increase, the greater the volume flow rate . As showed from the figure, the higer engine speed and the greater the load, the greater DPF exhaust pressure drop.

The pressure drop of fresh DPF. Figure 5 shows the exhaust flow conditions at the full load. As seen from the figure,the engine's exhaust flow rate range is from 0.015 to 0.157kg / s. According to the engine's universal characte-ristic test, the exhaust flow for all the engine's working conditions is consistent with exhaust flow at the full load,and not listed separately here.

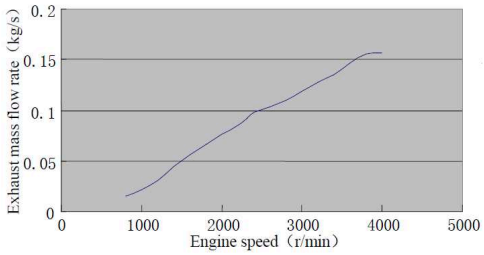

Fig. 5 The range of engine exhaust flow

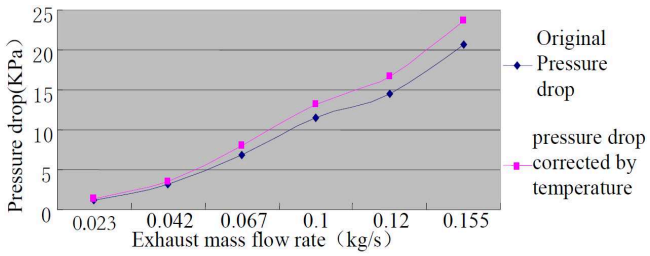

Fig. 6 The pressure drop characteristics of the fresh DPF

The experiment process needs to maintain a constant engine load and is tested at several speeds, during the entire testing process avoid that DPF is loaded more than 10%.The measurement interval covers the engine exhaust flow. According to preliminary experimental data select 6 wo-rking conditions as shown in Table 2 a, b, c, d, e, f to do pressure drop characteristics test of fresh DPF. Exhaust flow is obtained by adding the engine intake air flow and fuel consumption, which is ,for steady-state conditions, very accurate, and more close to the actual engine exhaust flow. As seen from the table, six exhaust flow conditions increase from 0.023kg/ to 0.155kg/s, covering almost the entire engine exhaust flow range.

Table 2 The working conditions of pressure drop

Working conditions	Exhaust temperature (℃)	Exhaust Flow (kg/s)	Pressure Drop (KPa)	Corrected pressure drop (KPa)
a	249.6	0.023	1.12	1.29
b	396.6	0.042	3.1	3.56
c	414.5	0.067	6.9	7.93
d	519.5	0.1	11.5	13.22
e	580.3	0.12	14.5	16.67
f	604	0.155	20.6	23.67

For the fresh DPF pressure drop measured at various conditions as shown in the table,is corresponding to the original pressure drop curve in the Figure 6. As seen from the figure, with the increase of the exhaust mass flow rate, DPF pressure drop increases, and at almost linear growth. However, we notice that, in Table 3, the exhaust gas temperature are different at a variety of conditions. This paper introduces a temperature correction for pressure drop of the DPF, you can make a three-dimensional pulse spectrum"speed - load - drop" into a two-dimensional pulse spectrum "exhaust flow - Pressure Drop,". And we have done this part to serve this idea. For DPF, its formula for exhaust pressure drop can be summarized as follows:

$$\Delta \mathrm{P} = \mathrm{c}q^2 \tag{1}$$

Wherein: Δ P is the pressure drop of DPF; q is the volume flow rate of gas; c is a const-ant. G enerally, the exhaust gas volume flow rate is substantially proportional to the exhaust gas temperatu re, therefore the exhaust gas temperature has a great influence on the DPF pressure drop.

Here, we introduce two states, state a and state b. Wherein, a represents the standard state, the s tate b indicates the detected actual engine operation state. According to the formula (1) and the gas equation of state, it is not difficult to come:

$$\frac{\Delta \mathrm{P_b}}{\Delta P_a} = \left|\frac{q_b}{q_a}\right|^2 = \left|\frac{T_b}{T_a} \bullet \frac{1+\Delta P_a}{1+\Delta P_b}\right|^2 = \left|\frac{T_b}{T_a}\right| \bullet \left|\frac{1+\Delta P_a}{1+\Delta P_b}\right| \tag{2}$$

In practical applications, the solution (2) is complicated and simplified to:

$$\Delta \mathrm{P_b} = \frac{8.57\times 10^4}{273.15+T} \bullet \Delta P_a \tag{3}$$

According to the formula (3), do the temperature correction for the measured pressure drop of the DPF,and the result is shown in Figure 6,and that is the pressure drop curve shown in the temperature correction. The corrected pressure drop curves is more universal, which is crucial to determine the DPF regeneration timing.

Summary

1. Build a test bench and do the external characteristics test of the engine. The emission of soot is large when Engine at low speed of external characteristics;while engine at high-speed and large load,soot concentration is relatively low which provides a preliminary test basis for pressure drop characteristics and regeneration characteristics

2. At the working conditions of the universal characteristics , the DOC inlet temperature and DPF inlet temperature are low on the whole .

3. Investigate the pressure drop for the fresh DPF and the DPF with different soot load amount and get the two dimensional pulse spectrum”exhaust flow -- pressure drop”by introducing temperature correction method to provide the basis for determining the timing of subsequent regeneration to lead to over-temperature.

Keywords: cable-stayed bridge; arch steel tower; dynamic characteristics; bridge in construction; completed bridge

Abstract. Based on Hangzhou Zhijiang Bridge, FEA models of arch steel tower in construction and completed stages are established by using ANSYS software. Before closed and completed are considered to compute the dynamic characteristics of different structural system for arch steel tower. The results show that the wind-reduced vibration can be generated easily. It can cause some bad effect on the construction, equipments and the safety of staff. So, some proper measures should be adopted to decrease the wind-induced vibration of arch steel tower in construction and completed stages. So, some meaningful references are provided for the further research on control of wind-Induced vibration for arch steel tower.

Introduction

Arch tower cable-stayed bridge[1-15] is a kind of new bridge in recent years. The bridge has a great innovation in some aspects of structure, technology and bridge model, but its structure is complex. Main arch is also the cable tower on modeling. The space geometric composition of the cable, the arch and girder makes structure stereo sense stronger, adapting to the surrounding environment and can be used as a landmark. At present, the domestic bridge for this type of arch tower cable-stayed bridge is less, and 246 m of Zhijiang Bridge is the longest span in arch tower cable-stayed bridges.

Zhijiang Bridge is a two-tower cable-stayed bridge with the span arrangement of 129+258+258+129 m. The main girder is steel box girder with the width of 40.5 m. Tower adopts the 97.5 m high door tower with the upper tower of rectangular steel box structure and the lower tower of concrete rectangular solid structure. The height of steel combined section to pile caps is 22.5 m. As shown in figure 1.

Fig.1 Zhijiang Bridge

Because of the unique shape and small damping of steel arch bridge, the reaction is more sensitive to the wind .As the current research is mainly concentrated in the conventional bridge tower[1-15], so there is no literature to mention the wind vibration control of steel arch tower.

Based on Hangzhou Zhijiang Bridge, this paper carried out dynamic characteristics research of the steel arch tower construction state and completed state, and provides a scientific reference for the research of wind induced vibration of arch bridge tower.

Dynamic Performance of 1/2 Completed

As shown in figure 2, the FEA model uses Beam4 unit to simulate the pile caps, concrete arch tower (T0), the arch steel tower section (T1 ~ T7), steel crossbeam, the support (column, horizontal and horizontal), main girder section and the next bracket (column, horizontal and diagonal). And MASS21 unit is used to simulate the crossbeam and the additional mass on the steel tower.

The first 10 order frequency and period of Zhijiang steel arch bridge tower of 1/2 completed are shown in table 1, the first two order models are shown in figure 4.

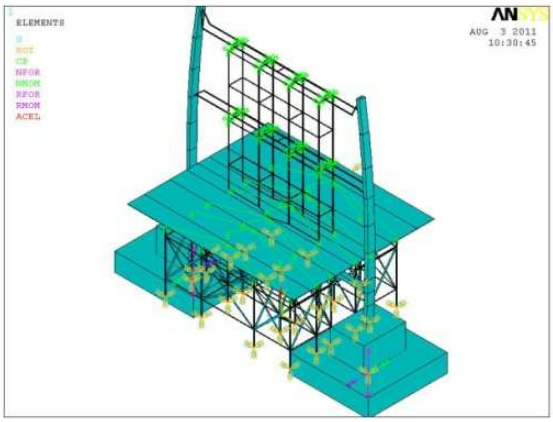

Fig.2 FEA model of 1/2 completed

Conclusion

We use ANSYS to calculate the dynamic characteristics of arched steel towers under five states (considering construction equipment), including: completion of the concrete section of the steel tower, steel tower built in 1/2, steel tower built in 2/3, before steel tower, after closure of steel tower, Figure 6 shows the effect of different arch-shaped steel tower construction states on the first six natural frequencies, we conclude:

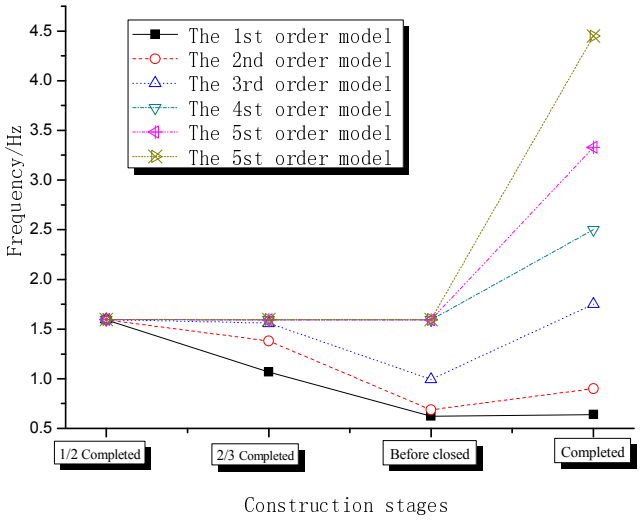

Fig.6 Effect of construction stage on frequency

(1) As the arch steel bridge tower construction, bridge tower constantly grow, the first and second-order frequency of the structure continue to decrease, this is because the arch steel tower become lack of horizontal linkages during construction, after the closure, its structural stiffness become larger , and vibration mode also change.

(2) Before arched steel bridge tower closed, 3 to 6 order frequency of structure also diminishes with the progress of construction, after the bridge tower closed, the third to six order frequencies substantially increase.

(3) We can see, the arch steel tower is lack of horizontal linkages during the construction, after the closure of arch steel tower, its structural stiffness become larger, and vibration mode also change. In other words: the state of construction and completion arch steel tower will be very sensitive to the wind, it is easy to cause the wind-induced vibration, and thus have a greater impact on the quality of the steel arch tower construction and the safe of construction equipment and people. Therefore, we need to take appropriate measures to reduce the wind-induced vibration of arch steel tower construction and completion.

Inhibition of Return Effect Reversed by Perceptual Load

Xingjuan LIU[1], Zhihao FAN[2], Jianzhong ZHOU[3*]

Department of Psychology, College of Humanities Jilin Agriculture University Changchun,130118, China

[1]email: xingzi1980@126.com, [*]email: xyzjz@163.com

Keywords: Inhibition of return (IOR), cue and target integration, Perceptual load.

Abstract. Perceptual load theory was considered to resolve the conflict between early and late selection models. We investigated whether perceptual load work well using IOR paradigm. The results showed that IOR disappeared in different level of perceptual load. The results indicated the onset time of IOR was influenced by perceptual load, indicating that perceptual load hinder the spatiotemporal correspondence between the cue and target integration.

Introduction

Perceptual load theory was considered to resolve the conflict between early and late selection models[1-2].According to this theory, to what extent the task-irrelevant stimuli are processed is determined by whether there are spare attentional resources left when they are used to process the task-relevant stimuli. If the current task has high perceptual load fill attentional capacity, irrelevant stimuli will be excluded before they interfere with task performance, but if perceptual load is lower the spare capacity will be directed automatically to the irrelevant information, which will then interfere with task performance [3-4]. Liu, Zhang and Zhou(2013) investigated whether the effect of distractors in IOR in discrimination tasks was changed by the location and number. The results showed that the trend of the general IOR effect was approximately the opposite in the two experiments. Different manner of cue target integration was adopted by participants when location and number of distractors were taken into account[5].

In present experiment, perceptual load was mad using IOR experiment paradigm(cue-target paradigm) participants responded to a letter (M) present in the peripheral box, which appeared simultaneously with high or low perceptual load. We measure the inter effect of perceptual load and IOR.

Experiment

Participants

Seventeen participants (12 females) participated in the present experiment (age20~23). All the participants had corrected-to-normal or normal vision. They were naïve to the purpose of the experiment and were paid after the experiment.

Apparatus and Stimuli

Stimuli were presented on a Dell/PC-compatible computer, and responses were recorded via the computer mouse using E-prime software. The target on each trial appeared in the central of one of two boxes, displayed to the upper or the down of fixation point (a plus sign "+"), which remained on the central of screen throughout the whole trial and only disappeared between trials. The distance between the center fixation and one of the peripheral boxes was 3.5° of visual angle. The target stimulus were white letter "M" (0.5°×0.5°).

Procedure

Fig 1 depicted the sequence of events on each trial. A fixation point was displayed together with the four boxes for 500ms, and then one of the boxes became white for 100ms, participants were required to gaze at the fixation point and not scan. Following the cue, the fixation point was

displayed together with the two boxes for 50ms. Then the central fixation cued for 100ms. The target was displayed at any of peripheral position for 2000ms or until response. If no response was obtained within 2,000 ms after target offset, then the next trial began.

All possible combinations of the cue location and target location variables were presented randomly within a block of trials. The experiment was interrupted every 96 trials to allow the participants to rest. Participants were instructed to press right key of mouse to letter "M" and participants also were reminded to maintain central fixation throughout the trials. They were instructed to discriminate targets and respond quickly while avoiding errors.

Design

The experiment had a 2×2×2 within-subjects variables, cue validity (valid, invalid), SOA (400ms and 1000ms), perceptual load (low, high). A total of 64 practice trials were run before the 512 experimental trials. Participants sit about 50cm from the screen in a dimly lit, quiet room.

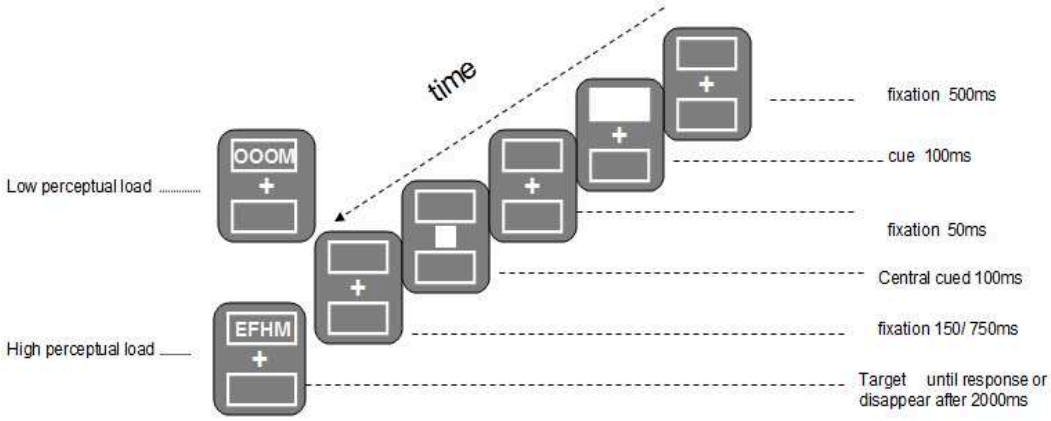

Fig.1 Illustration of Sequence and timing of a trial in Experiment

Results

Trials with RTs smaller than 342ms (anticipations) or larger than 1125ms (misses) outliers were defined as the saccade latencies. Fig. 2 illustrates the results of experiment.

RT of correct trials was submitted into a repeated variance analysis (ANOVA). The main effect of cue validity was significant, $F(1, 16) = 16.02$, $p<0.001$, RT was faster to targets at the valid location (754ms) than at the invalid location (782ms), which was the typical facilitation effect. The main effect of perceptual load was significant, $F(1, 16) = 9.30$, $p<0.01$, RT was faster to targets when perceptual load was high than when perceptual load was low. The main effect of SOA was significant, $F(1, 16) = 10.02$, $p<0.001$, RT was faster to targets at 400ms than at 1000ms. The interaction between cue validity and perceptual load was not significant, $F(1, 17) = .767$, $p>0.05$.

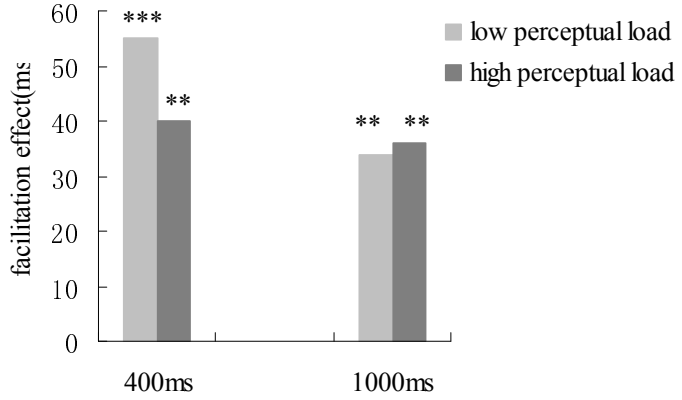

Fig. 2 Facilitation effect IOR effect in the peripheral target detection task as a function of cue validity, SOA and in the condition of low perceptual load.

Discussion

Lupiáñez, et al. (2007, 2010) propose a "three hypothetical effect" theory [6-7], which suggests that the time course of IOR is influenced by spatial orienting benefit, onset detection cost and spatial selection benefit. Peripheral cues trigger a short-lived exogenous spatial orienting of attention, thus improving target perception and/or responses to it, which is called "spatial orienting benefit". The cue-target integration process would facilitate processing by helping to select the target location in advance, an effect that is represented as the "spatial selection benefit". However, the integration of the target within the cue representation would produce a cost in detecting the onset of the target, which is "onset detection cost". The facilitation or inhibition of responses to peripherally cued targets would result from the sum of the detection cost, spatial benefit, and spatial orienting benefit [8]. The results showed that facilitation effect was significant when perceptual load was low and high. IOR magnitude was different with previous research when an interference letter was present together with the target [9].

In present experiment, the disappearance of IOR when perceptual load was conducted indicated that the perceptual load is critical for onset of IOR, indicating that there has no spare attentional resources to process other stimuli and they will be excluded before they interfere with task performance in the current task. The perceptual load distractors hinder the spatiotemporal correspondence between the cue and target integration. Another prediction that can be drawn from Lupiáñez et al.'s view is that in our experiment, cue and target integration was more harmful than in the common cuing tasks where adding perceptual load. This suggestion would surely predict later onset of IOR in those experiment conditions.

Brushless DC Motor Speed Control System Based on Fuzzy PID Control

Yihui Zhang[1,a], Lepeng Song[1,b]

[1] Chongqing University of science and technology, Chongqing, China

[a]zhangyihui1@163.com, [b]slphq@163.com

Keywords: brushless DC motor; fuzzy PID control; Matlab/Simulink simulation; fuzzy control

Abstract. Brushless DC mo tor speed control system is a multivariate, strong coupling, non linear, time-varying complex system, but adopting traditional PID control method to carry ou t control is difficult to achieve good control effect A kind of PID controller with fuzzy algorithm setting on-line PID parameters automatically was designed and applied in brush less DC motor speed control system, using the voltage , speed and torque equation of brush less DC motor, according to the parameters of the mo tor, the controler adopts fuzzy theory to adjust the PID parameters, in order to obtain high-precision speed control Results of simulation experiment show that the fuzzy PID control method compared with normal PID control is with better control performance, non overshoot quick velocity response, higher control precision and good rubustness, which is insensitive to the parameter chattering and many disturbances.

Introduction

Brushless DC motor is a permanent magnet motor, its change is realized by electronic circuit outside the. Permanent magnet brushless DC motor speed control system is a nonlinear, multivariable, time-varying system[1-2], parameters tuning difficult, a set of tuning the parameters can only be a good control effect in a smaller range, when the parameters change more than a certain range, the system control effect is poor, resulting in conventional PID control is difficult to to meet the requirements of the system[3-4].

Although the modern control theory. Some new results include linear regulator based on pole assignment and optimal control, the exact feedback linearization, model reference adaptive control into the motor control technology, effectively improves the running performance of Brushless DC motor, but the modern control theory still rely on mathematical model of motor accurately, the performance of the system influenced by the variation of istics imotor parameters and various uncertain factors[5-6]. Since 1965 USA University of California cybernetics expert Zadeh fuzzy mathematics, the theory and method of improving, short decades, fuzzy control (Fuzzy Control) is widely used in natural science and social science and engineering control field[2-4].

This paper presents a speed control system of Brushless DC motor based on adaptive fuzzy PID model. The model input parameters deviation and deviation change between the given speed and actual speed rate as fuzzy control inference machine, fuzzy theory, adaptively adjust the PID parameter, and the simulation of control system in MATLAB. The simulation results show that, the control system of quick response, small overshoot, and strong robustness, dynamic characters obviously better than that of traditional PID control and the fuzzy control.

1 mathematical model of the brushless DC motor

Brushless DC motor with a rectangular current wave, trapezoidal back emf. Mutual inductance of stator and rotor is nonlinear. Therefore, in the analysis and Simulation of BLDCM control system, in order to establish the simplified simulation model, make the following assumptions: the complete symmetrical three-phase winding, the air gap magnetic field for Fang Bo, stator current, rotor magnetic field distribution is symmetric; ignore the cogging, commutation process and armature reaction effects; circuit is not saturated, regardless of eddy current and hysteresis loss.

Voltage balance equation BLDCM:

$$\begin{bmatrix} u_a \\ u_b \\ uc \end{bmatrix} = \begin{bmatrix} R & 0 & 0 \\ 0 & R & 0 \\ 0 & 0 & R \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \frac{d}{dt} \begin{bmatrix} L-M & 0 & 0 \\ 0 & L-M & 0 \\ 0 & 0 & L-M \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} \quad (1)$$

Type u_a, u_b, u_c as the phase windings of the motor phase voltage; i_a, i_b, i_c as the phase windings of the motor phase current; e_a, e_b, e_c opposite electromotive force of the phase windings of the motor; R, L, M three-phase winding phase resistance, self inductance and mutual inductance between phases.

Electromagnetic torque equation BLDCM:

$$T_{em} = \frac{p_n(e_a + e_b + e_c)}{\omega_n} \quad (2)$$

As the electrical machinery velocity in type, as the pole number, electromagnetic torque.

The motion equations of the motor:

$$T_e - T_L - B_\omega = J\left(\frac{d\omega}{dt}\right) \quad (3)$$

For the electromagnetic torque of type, as the load torque, B damping coefficient, J for the moment of inertia, the motor mechanical angular velocity.

Fuzzy adaptive control system design

Brushless DC motor fuzzy PID control system structure diagram as shown in figure 1. First calculate the deviation of the actual speed of the motor and the speed of n given NR E and deviation change rate of EC, then they are fuzzy, fuzzy E and EC by the fuzzy control rule reasoning, fuzzy solution to obtain Kp, Ki and kd. In the control process, parameter online real-time modification of conventional PID controller, the conventional PID controller of Brushless DC motor speed regulation.

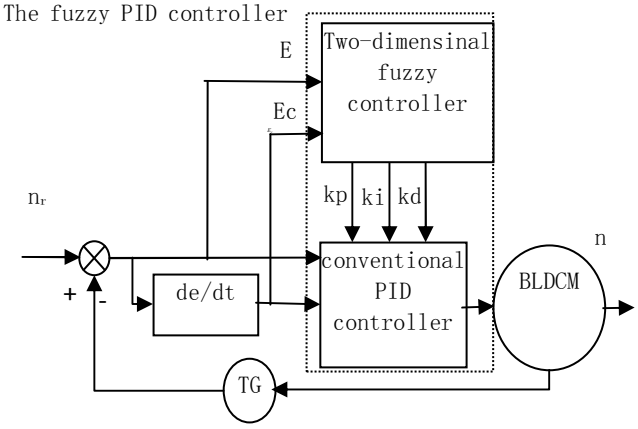

Figure 1 BLDCM fuzzy PID control system structure diagram

The design steps of fuzzy adaptive PID control system are as follows: the controller input variables and the actual speed and the given speed error E and error rate of change of EC, the output variables through the PID parameter KP, Ki, KD adjusted. Domain domain are set to [-6,6] set the input language variables and the output variables of the fuzzy, fuzzy language variable selection 7: NB, NM, NS, ZO, PS, PM, PB. The ambiguity solution method using center of gravity method, the weighted average method.

Membership function using triangular distribution function. On KP, Ki, KD were tuning, fuzzy control rule of the three as shown in Table 1, 2, 3 show.

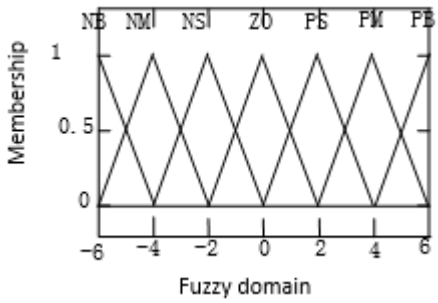

Figure 2 The input and output membership function curve

Taking into account the coverage degree and the sensitivity of the domain, robustness and stability principle, selection of input and output fuzzy membership function uses triangle membership function in fuzzy membership function of fuzzy logic toolbox in the editor. As shown in figure 2.

According to the control characteristics of the rotated speed of Brushless DC motor, induction of Kp, Ki and Kd fuzzy control rules, the fuzzy inference to derive the fuzzy relation, according to the reasoning of fuzzy relation and the input variables E, EC synthesis, Ki and Kd Kp are output linguistic variables, and then converted into precise speed actuator can accept the value after defuzzification operation.

Fuzzy reasoning using CRI (CRI) max-min synthesis of Mandan I reasoning method, reasoning, according to the relationship between fuzzy implication operator, fuzzy min and Max, select / maximum and minimum 0 operations as the synthetic operation, the fuzzy output value [5]. Fuzzy solution by using the weighted average method. In order to realize the real-time control, the system to meet the rapid control requirements, the off-line calculation form, namely fuzzy control rules to control query table, the reasoning process is simplified to a lookup table operation, it is easy to realize the real-time control of fuzzy controller through the look-up table, to improve the response speed of the system.

Simulation results

To establish the system simulation in the Matlab/Simulink software platform, system parameters: rated power of 3 kW 220V; rated voltage; rated current is 13164A; rated torque Rated speed is 22N*m; 1460r/min; moment of inertia for 0157kg*m2; each phase resistor of 0.21 per phase inductance is 0.21mH. Simulation of control as shown in figure 3. Through the above methods, the design parameters of fuzzy PID control in the parameter perturbation and disturbance simulation test input, simulation experiments with traditional PID control in the same parameters were compared. The simulation curve 5 as shown in Figure 3, figure 4, figure.

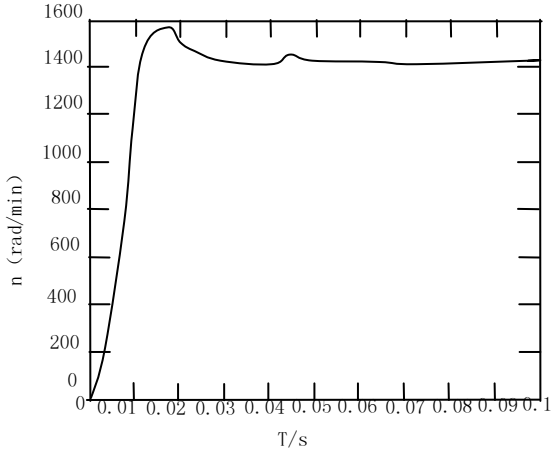

Fig. 3 Block diagram offuzzy PIDcontrol system simulation

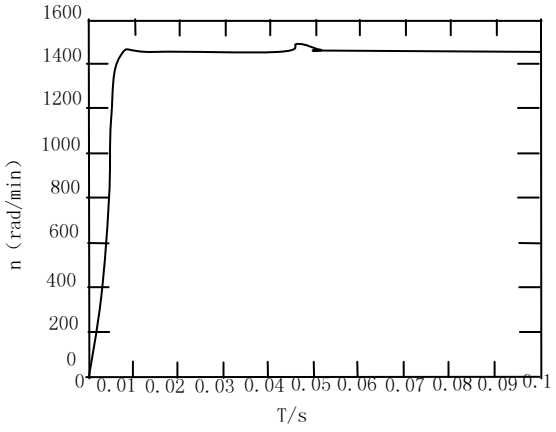

Fig. 4 Conventional PID controller speed simulation curve

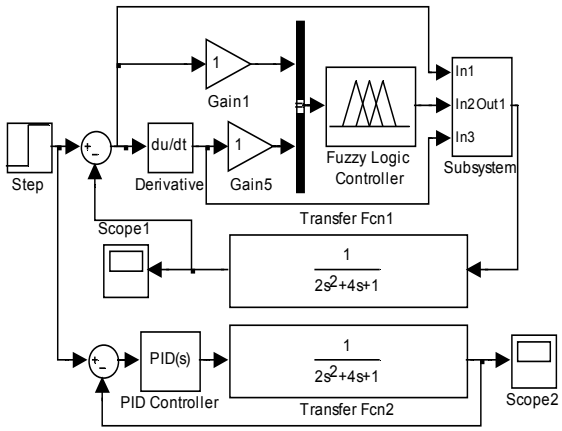

Fig. 5 Fuzzy PID controller speed simulation curve

Two kinds of controller performance data from the simulation curve and table 4 summarizes the apparent: using brush DC motor without speed fast response, no overshoot fuzzy adaptive PID control; in the t= 0.04 s, response curves fluctuation system load when the mutation rate, and quickly return to the rated speed, short adjusting time and strong anti-interference ability, a good dynamic characteristic, greatly improving the robustness of Brushless DC motor system.

Table 4 Performance parameters of two controller

The two controller	Overshoot δ/%	Regulation time ts/s
The conventional PID controller	9.85	0.029
The fuzzy PID controller	0	0.011

Conclusion

This paper describes the design of a non brush DC motor double closed loop speed regulation system based on fuzzy PID controller, PID controller is adopted in the current loop, speed loop adopts fuzzy PID control. Changes of input parameters based on. Using the principle of fuzzy on-line self adjustment of PID parameters, the motor during start-up and operation load case, on MATLAB, a simulation experiment is carried out. The simulation results show that, the fuzzy PID control scheme is proposed in this paper can improve the response speed of Brushless DC motor system, restrain the overshoot, and improve the control accuracy, robustness and dynamic and static performance, its control performance is superior to the conventional PID control.

Keywords: Control System; Improving; Experiment; Algorithm

Abstract. There are many factors that can affect network performance, such as delay, packet loss and capacity utilization. Vehicle handling directional stability has been more and more important, experiments for steering wheel corner step input response, steering oil tank response property, steady state turning and steering angle of all steering wheels were conducted in this paper, the experimental results show that multi-wheel steering system can fulfill its function very well and reach target angle, it provides a new method for researching for the vehicle handling directional stability.

Introduction

Structure of the multi-wheel steering electrohydraulic proportional control system can be divided into the electronic control unit (ECU) and the actuators[1][2][3]. The core of the whole control system is the electronic control unit (ECU), which completes the acquisition of the input feedback signal and the action of actuators. The actuator which is the hydraulic valve system includes oil source, electro-hydraulic proportional valve and hydraulic cylinder. According to PWM wave control signal of ECU output, the ratio solenoid coil of electro-hydraulic proportional valve gains a certain current, therefore controls the size of its force or displacement control valve proportional size of the opening. Extensional structure of the multi-wheel steering vehicle is shown in Fig.1.

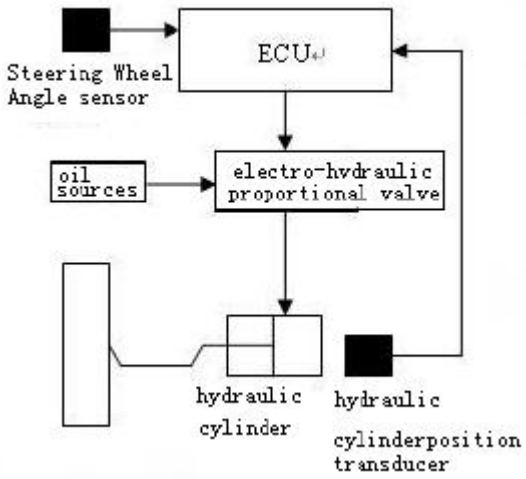

Fig.1 Diagram of multi-wheel steering vehicle control system

Most of modern cars use the front wheel steering to meet steering movements in the case of the general road condition and speed, with the development of the modern road transportation system and the advanced automobile technology, vehicle speed becomes faster and faster, so the motor vehicle handling directional stability has been concerned more than ever, one of the primary means to improve the motor vehicle handling directional stability is multi-wheel steering technology, which can better meet the Ackerman theorem and reduce tire wear. In this paper, an 8 × 8 wheel

vehicle steering mechanism has been transformed, developed a multi-wheeled vehicle steering wheel and its control system, and conducted bench and road tests[4][5].

Experimental Setup

Multi-wheel steering is a very important and effective way to improve vehicle maneuverability and handling stability. In order to get control parameters, verify electronic control unit of the control law and working performance, we turned to experiments carried out several rounds of bench and road test the car[6].

The device of the multi-wheel steering system's bench test

To verify the law of the control and test the working performance, a series of bench experiments were performed under the condition of the electronic control unit installed in the body after transformation, multi-car wheel steering.

The contents include the step input response of the steering wheel angle, and bench test bench test validation control law, steering cylinder response experiments, steady-state experiments and the rotary steering wheel steering angle measurement experiments. Car steering wheel like the overall layout of the control mechanism is shown in Fig.2.

Fig.2 General overall layout of multi-wheel sterling's control mechanism

The bench test of steering wheel angle step input response

The electro-hydraulic proportional control system is mainly actuators in multi-wheel steering control system; it is composed of the oil sources, electro-hydraulic proportional directional control valve and asymmetric hydraulic cylinder. Oil sources include tanks, pumps, filters, etc. Electro-hydraulic proportional valves are symmetrical, and hydraulic cylinder is asymmetric cylinders, forms a system that symmetric electro-hydraulic proportional valve controls asymmetric hydraulic cylinder. Under the control of the ECU, the system which makes use of hydraulic oil provides the oil sources to complete the actions required steering wheel.

Experimental purpose: to test electro-hydraulic proportional valve on the steering wheel input signal response performance in the multi-wheel steering system. Experimental methods: The steering wheel angle input is set to step excitation signal .The spool opening step response is measured in this case. And then by adjusting the electro-hydraulic proportional valve PID control proportional, integral and differential parameters of the optimal response. The experiment condition to do the steering wheel is 0-150 angle input step stimulus and 0-150 spool opening under the more response-order experiments. Experimental results are shown in Fig.3.

Waveform can be obtained from the above, the more order average response time is 0.14s, a positive step response is faster than the negative. To stabilize the target in a certain overshoot before the oscillation, the maximum overshoot of 3.3% (normal range within 10%), which is within the normal range.

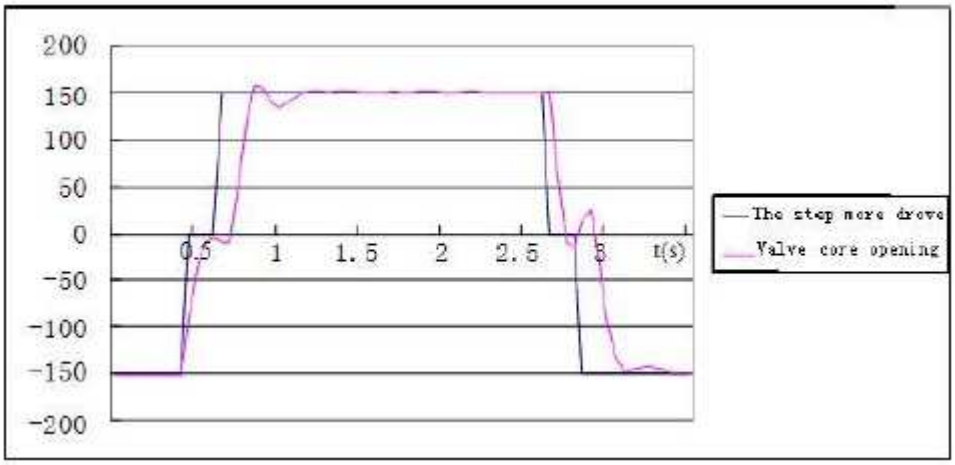

Fig.3 Steering wheel corner inputs response characteristic

The response experiment of steering cylinder

Experimental purpose is to test the steering cylinder on the steering wheel input signal response performance in the multi-wheel steering system. Experimental method is to use the steering wheel to rotate at different speeds in both directions around the maximum point, record the experimental data, analysis of response characteristics of the fuel tank. The results are shown in Fig.4 and Fig.5.

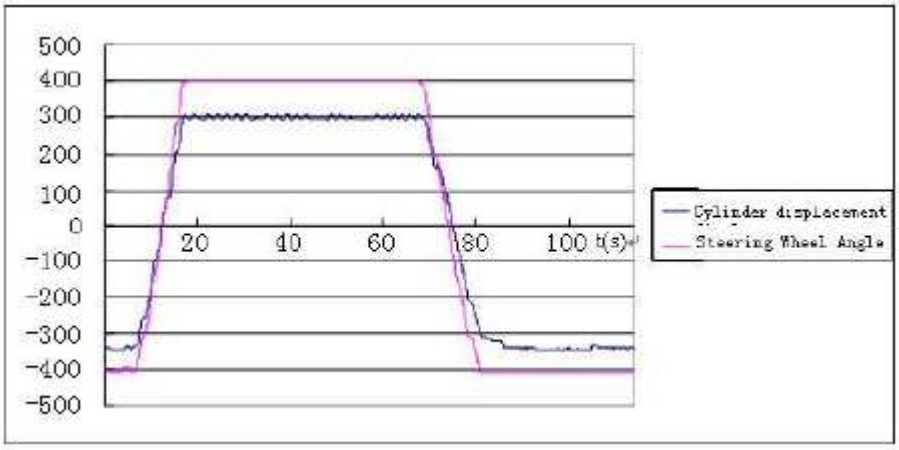

Fig.4 Hydraulic cylinder's response characteristic when steering wheel corner change is quick

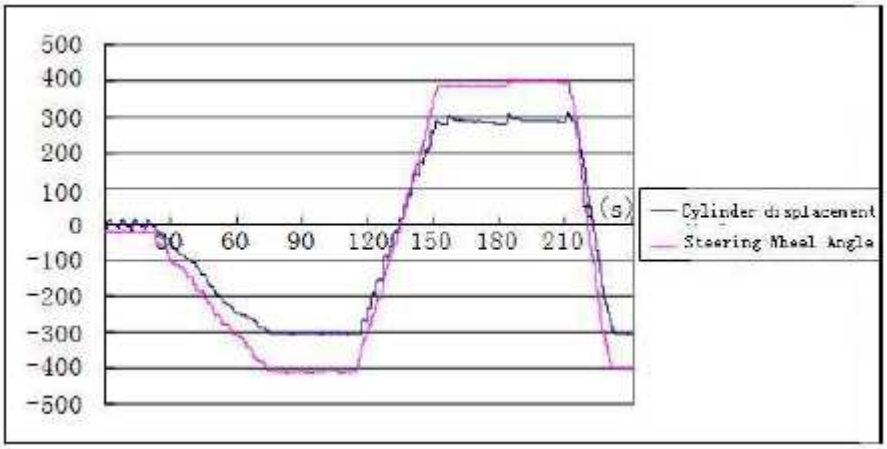

Fig.5 Hydraulic cylinder's response characteristic when steering wheel corner change is slow

Conclusion

The bench test of steering wheel angle step input response verified the second bridge turn rotation angle of the input control signal transient response characteristics. Experimental results show good dynamic characteristics. The reaction time is shorter, a smooth transition process. The steering implementation body that is the hydraulic cylinder in terms of response time or response for the accuracy of the results has been good. Multi-wheel steering system can achieve its function well and its target angle. The multi-wheel steering system has greatly enhanced the mobility of wheeled vehicles, to achieve the desired function. Through using proper control policies and control parameters, steering the mismatch occurred during sync basically resolved the problem. It achieved good control effect.

Keywords: Grasp; Image; Robot Hand; Expert System

Abstract. Because the traditional linear vectorization methods have some shortcomings including processing data slowly, being sensitive to noises and being easy to be distorted. Fuzzy rules and its inference mechanism are the assurance of achieving feature fusion. This paper has a design and analysis on the dual thumb pneumatic flexible robot hand base on the active flexible bending joints we have developed. The flexible joint is composed of four elongation artificial muscles with parallel arrangement. The robot hand has five multi-actuated fingers each with three flexible joints. To improve the flexibility and stability of grasp, the other four fingers are orthogonal and symmetrical except the middle finger, which forms the dual thumb oriented grasp model. Furthermore, we study on the position and posture of fingers applying the parameterized homogeneous transformation to the large deformation and nonlinear problems of flexible joint.

Introduction

Genetic algorithm (GA) is an effective probability searching algorithm based on the natural selection and the genetics principle, and it carries on the search and the optimization through the simulation organic evolution, and it automatically gains and accumulates the related knowledge of searching space in the searching process, and it controls the searching process to obtain the optimal solution of the question.

The simulation and experiments verifies the model and the grasp capability of robot hand. The robot hand we developed has good flexibility and compliance, and easy to soft control, which provide a new way to solve the entire flexibility of robot hand[1][2]. This algorithm has many characteristics such as automatic identification of antigen, feature extraction, the diversity of immune body, distributional examination, learn and memory, self-plan etc, and it is also parallel distributional self-adaptive system which has the great potential in the application of intelligent computation. In recent years the immunity genetic algorithm has obtained the widespread application in many domains because it can effectively maintain the diversity of population and eliminate not mature astringency and the oscillatory occurrences. The reference presented an immunity genetic algorithm which extracts vaccine from the system knowledge and vaccinates to the evolution process, thus, it can fully use the system message, but the algorithm has not considered the diversity of population which influences the evolution process[3][4][5].

Structure and Principle of Flexible Robot Hand

Flexibility and universality are two characteristics of robot hand we developed. All joints of robot hand are pneumatic and flexible which improve the flexibility of robot hand; the universality is implemented by the amount and arrangement of fingers.

Structure of Bidirectional Active Flexible Bending Joints

In Fig.1, the flexible joint we developed is mainly composed of four elongation artificial muscles and flanges, with two ends fixed on the flanges. It can axial elongate and bend two-dimensional two-way control in space simultaneously, and it has three degrees of freedom. Through controlling the air pressure of the four artificial muscles, the joint can bend anti-stretch, abduct and adduct.

For example, ensuring the air pressure of muscle is equal to muscle and more than muscle and muscle simultaneously, the joint can bend about Y-axis. The degree of bending is determined by the pressure differential controlled by the proportion valve. The bending of joint behaves like the nonlinear beam with large deformation which is characterized by the elongation of axis and the bending angle of the end.

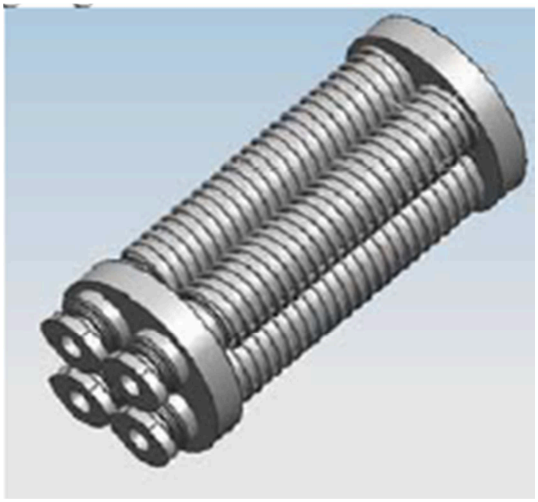

Fig.1 Structure of joint

For ease of comparison and visualization, the discriminator gains were normalized. The discriminating performance curves of the three algorithms with the correlator placing d = 0.25 (chip) and d = 0.5 (chip) are presented respectively in Fig.2.

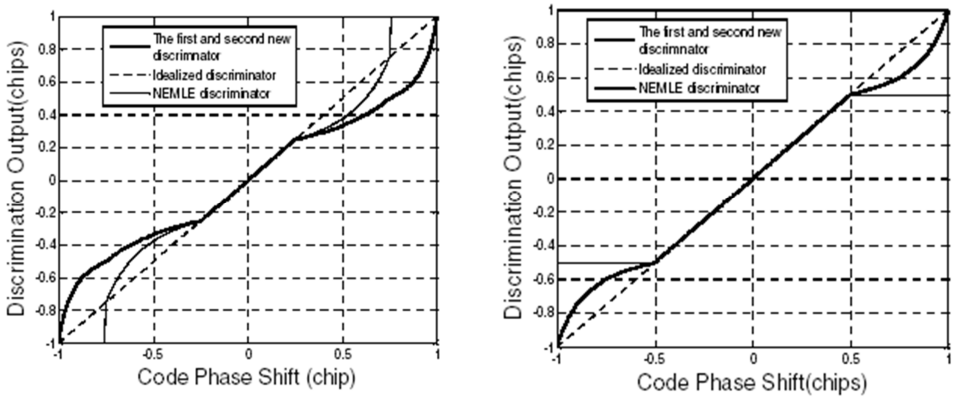

Fig.2 Discriminating performance curves with the correlator placing *d=0.25*(*chip*) and *d=0.5*(*chip*)

The analysis of the comparison obtained from Fig.2 is that, discriminator is better when d=0.25(chip), and the two new discriminators are better when d=0.5(chip).

Structural Design on Finger of Robot Hand

In Fig.3, The flexible finger is made of three pneumatic flexible joints connected in series, with the two ends of joint fixed on the wedge plate. One finger has one degree of freedom and two degrees of maneuvering. Thanks to the wedge angle of wedge plate, the bending angle about the orthogonal directions will increase to 3 ±120° at the maximum working pressure, which greatly improve the flexibility and grasp range of robot hand.

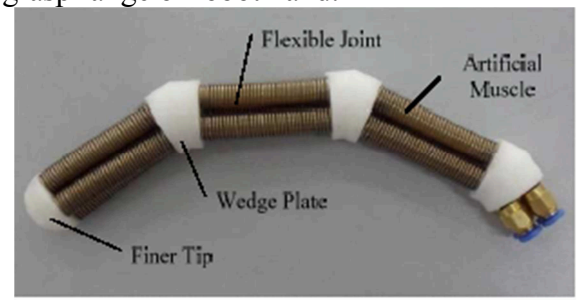

Fig.3 Structure of finger

Structural Design of Five-Fingered Flexible Robot Hand

The multi-fingered robot hand is composed of five fingers, and each finger is made of three bidirectional active flexible bending joints in series. The other four fingers are orthogonal and symmetrical except the middle finger, and the palm is axial symmetry along the middle finger. This distribution of fingers has good adaptability with the variety of object to grasp and it is easy to achieve the geometry- closed and force-closed.

For convenience and computational efficiency, five fingers are just the same to each other. The geometry characteristic forms the dual-thumb oriented grasp model in which four fingers predominate, or the thumb oriented and the others to cooperate it.

Simulations and Grasp Experimental Analyses on Position and Posture of Finger

We obtain the coordinates of typical control points and related points using Matlab. Fig.4 shows the trajectory and the pose of the finger. According the coordinates of each finger within palm coordinate system, as shown in Fig.5, we get the limits of posture of finger when the air pressure is 0.35MPa. It illustrates that the simulation results is consistent with the theoretical model. Bending grasp can manipulate the sphere, box, triangle object and other arbitrary shape objects effectively using one to five fingers. It is obvious that the bending grasping is the main effective work mode of the robot hand.

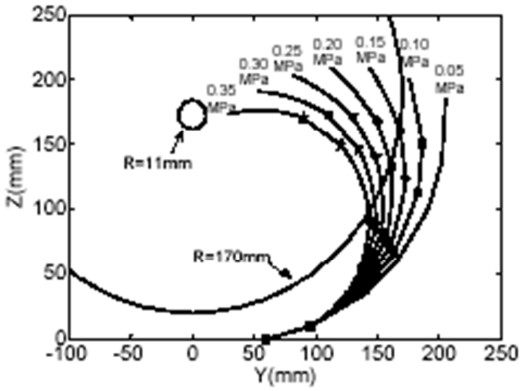

Fig.4 Finger trajectory when bending

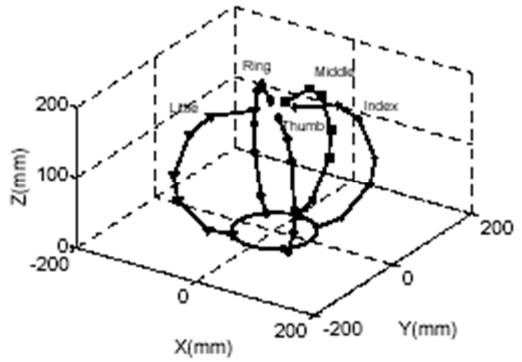

Fig.5 Pose of robot hand when bending grasp

Conclusion

This paper proposed a dual-thumb pneumatic flexible robot hand. It focuses on the pose and posture of the flexible joints, fingers and robot hand on the basis of analysis of their structures and performances. Improved algorithm brings the question space and the corresponding solution space into correspondence with the antigen and the immune body, and it controls the reproduction of the partial optimal solution through the density. The algorithm can improve the search speed because chaos is introduced in the initial population and diversity adjustment. The algorithm can carry on the local optimization and increase precision nearby the optimal solution. The result of experiment shows the algorithm validity. We can draw a conclusion from experiment comparison, the paper's algorithm makes average movement algebra small, and the algorithm overcomes the shortcoming of slow convergent speed which generic algorithm has, and the algorithm is superior to convergent speed of immune genetic algorithm. The simulation results and the experiments prove the validity of the theoretical model. It shows that the robot hand has good flexibility and compliance, and easy to soft control. It has strong and continuous adaptability, and can perfectly do the actions of grasp, clamp, flip and fiddle etc. It is agile and tightly to grasp the small object within 1 kg, and possesses good practical value.

Keywords: finite element; pipe; crack

Abstract. Pipeline in the entire oil and gas transportation industry play an important role and in the soil is corroded in order to produce the stress corrosion crack. The topic analyzes and calculates cracked pipeline with finite element method by use of ANSYS software mainly, and provides the theory basis for safety evaluation of pipeline.

Introduction

The engineering system can be converted to the finite element system by finite element method, and it makes up of node and element in order to Replace the Original engineering system, and it can transform into the mathematical model, that get the solution of the finite element system with the nodes and elements. Complete finite element model in addition to the node and the element, include the boundary conditions of the engineering system personally, the constraint conditions, and the negative force load etc [1].

Before Processing

Create a geometric modeling

Using good graphic user interface (GUI) of the ANSYS software establishes directly geometric model. As shown in fig.1.

Mesh generation

Model that has been created can be meshed, and the division of grid needs set up grid cell type, material properties, etc.

Selection of unit type：The model is three dimension unit, that selects 20 nodes hexahedron elements the of the Lagrange type, that the interpolation function is comparatively easy. As two-dimensional rectangular L shape function, the three dimensional regular hexahedron L shape functions is respectively "three linear", "three second", "three three times" and so on.

"Quadratic element" has 20 nodes, as shown in fig.2.

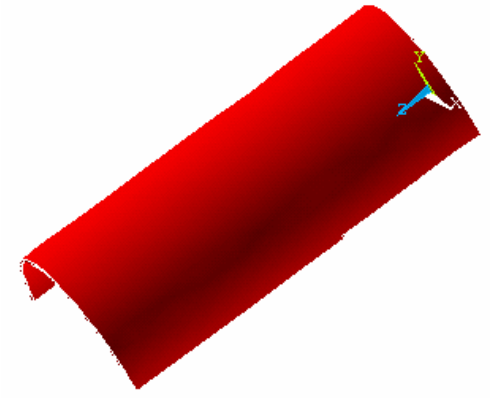

Fig.1. Geometric model

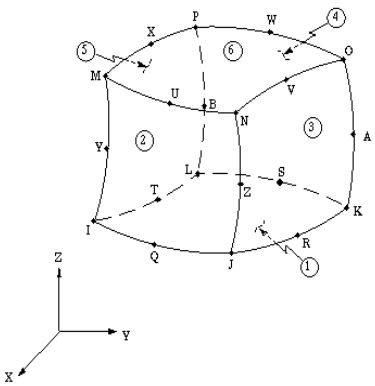

Fig.2. SOLID95 3-D 20-Node Structural solid

About any argument is secondary, its shape function as the vertices

$$\Psi_i^{(0)}(\xi,\eta,\zeta)=\frac{1}{8}(1+\xi_i\xi)(1+\eta_i\eta)(1+\zeta_i\zeta)(\xi_i\xi+\eta_i\eta+\zeta_i\zeta) \quad (1)$$

Among them （ξ_i,η_i,ζ_i) for the itch the vertices of the natural coordinates

$$\xi_i=\pm1,\eta_i=\pm1,\zeta_i=\pm1, \quad (2)$$

Among them （ξ_i,η_i,ζ_i) for the itch the vertices of the natural coordinates

For the surface nodes: $\xi_i=0,\eta_i=\pm1,\zeta_i=\pm1$ (3)

$$\Psi_8^{(0)}(\xi,\eta,\zeta)=\frac{1}{4}(1-\xi)^2(1+\eta_i\eta)(1+\zeta_i\zeta) \quad (4)$$

For the surface nodes: $\xi_i=\pm1,\xi_i=\pm1,\zeta_i=0$ (5)

$$\psi_i^{(0)}(\xi,\eta,\zeta)=\frac{1}{4}(1-\zeta^2)(1+\eta_i\eta)(1+\xi_i\xi) \quad (6)$$

For the surface nodes: $\eta_i=0,\xi_i=\pm1,\zeta_i=\pm1$ (7)

$$\psi_i^{(0)}(\xi,\eta,\zeta)=\frac{1}{4}(1-\eta^2)(1+\xi_i\xi)(1+\zeta_i\zeta) \quad (8)$$

Another type is MATRIX50 as shown in fig. 3.

Define the material properties

Material properties is the physical properties, can define a variety of material properties as unit. Different properties show different material number. Pipeline that is rigid material select 60 s.

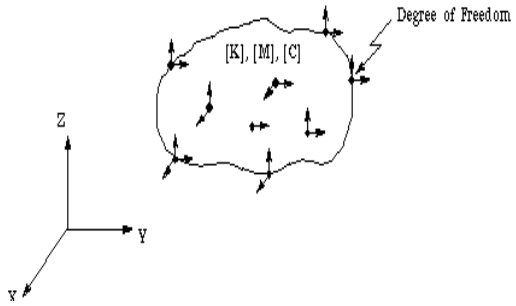

Fig. 3. MATRIX50 Super element

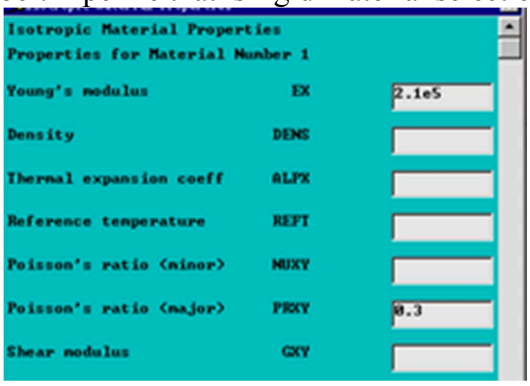

Fig. 4. Linear material properties

Linear material properties includes elastic modulus (EX, EY, EZ), poisson's ratio (PRXY, PRYZ, PRXZ), shear modulus (GXY, GYZ, GXZ), thermal expansion coefficient (ALPX, ALPY, ALPZ), etc. But some properties of analysis are irrelevant. In the analysis, the thermal conductivity of materials is no meaning to analysis [2]. Input material in warehouse can also define your own material attribute. Depending on the type of rigid material selection as shown in fig. 4.

Net and control

Grid control can control unit in shape, mesh density, node location, local grid, etc., In the accuracy of the models and moderate cost on computer resources properly the grid density is important. it that is too thick not want accuracy and that is too thin is likely to waste a lot of computing resources, that includes unnecessary stand of time and space. For meshing grid, I chooses the precision of the part of the grid of 8, another part of the precision of the grid is 5, the default precision is 6, 1 is the fine grid, 10 is the coarse grid. [3]

After defining the element properties and the grid control, can point network entity model, it is a solid model into finite element model of step.

Solid Modeling can be meshed after defining the element properties and parameters as shown in fig. 5.

The Problem Solving Process

DOF constraints are constraining the node degrees of freedom. The basic variables of the node degrees of freedom are to solve the equation, you can also specify a node degrees of freedom value,

once the value is specified, the solution will remain the same. Set the DOF is set its degrees of freedom value [4]. Constraint degree of freedom can be added in the online, on the surface, key point and nodes. Constraints are on surface crack of pipes. As shown in fig.6.

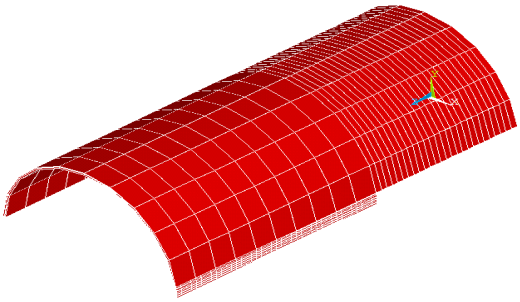

Fig. 5. Model grid

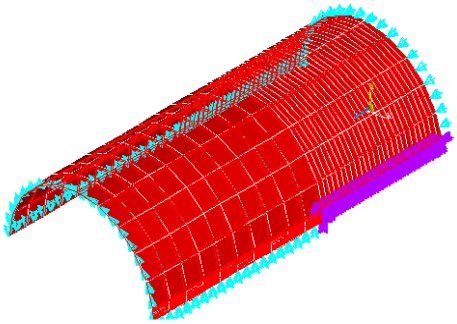

Fig.6.Constraints with crack pipe

I put crack pipes into unit strength, as a beam element, the pressure load on both ends of the side of the beam and that can be used to pressure and pressure gradient. For the lateral pressure, the size of the force per unit length, along the tangential and normal respectively, set up JOFFST to 1, can be simplified as the any place of the force on the beam element [5].

With pipeline analysis of crack is linear problem; it is ok to use the program default, namely a new analysis of static problems, using the current load step to solve.

The default form of analysis is a static analysis, ANSYS procedure for linear static analysis, the structure of the balance equation is: $[K]\vec{u} = \vec{F}$ (9)

Among them, called the overall stiffness matrix, for the node displacement vector of load vector, including applied to load on the structure and the structure of reaction load. That is: $[K]\vec{u} = \vec{F}^{r} + \vec{F}^{nd} + \vec{F}^{e}$ (10)

The above equation is the first reaction load on the right, the second is applied to the load of nodes, and the third is applied to unit load.

Any model, through the finite element discrete equation has the same form:

$[K]\vec{u} = F^{a}$ (11)

Among them, the coefficient matrix; for the location of the DOF freedom vector, load is applied. So, the problem is to solve the above equation. If it has nothing to do with equations for linear; otherwise, is nonlinear. Solution of the static analysis is the simplest form, but it is also the foundation of other forms of solving. The pipe selection result diagram is as follows: (unit) Fig. 7.

Post Processing

Post-processing is to check the analysis results. Read the data： ANSYS is not the result data into database automatically, so you need to take the results into the database.

Deformation shows： Deformation shows is mainly used for graphic structure deformation influence of external load, by which the direction and size of structure deformation can be obtained. Deformation is small, so the figure is a sign for the nature of the deformation, but not completely the size of the deformation is on the diagram. Deformations enlarge fig. 8.

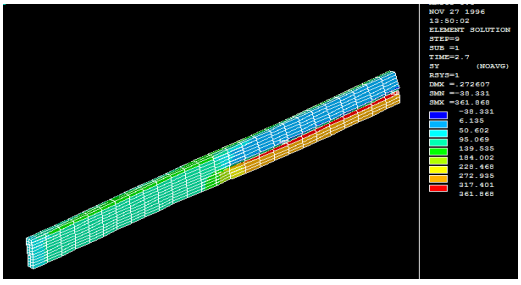

Fig. 7. Pipeline analysis diagram

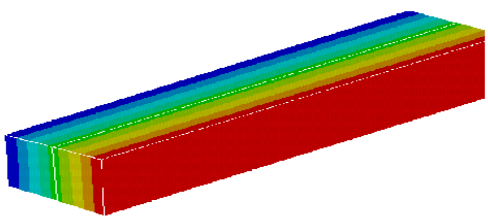

Fig. 8. Deformations Show

Conclusion

The values of the maximum stress of crack pipe cracks are in the corners fig.8. in red mark from the above results. it perfectly match with theory calculation, so the design completely meets the requirements.

Keywords: Magnetic Memory Testing; ANSYS Simulation; Correlation Effect; Stress Concentration

Abstract. To study the correlation effect of multiple defects of metal magnetic memory (MMM) testing technology, the stress-magnetization effect on 20# steel specimen with dual defects under exercise of the geomagnetic field and tensile load is simulated by using the finite element analysis (FEA) software ANSYS. With the stimulation, the magnetic flux leakage (MFL) distribution with different measured paths and different lift-off values of the surface specimen is given. The results showed that the correlation effect of dual defects produce more severe stress concentration phenomenon on the associated region of ferromagnetic specimen, and had no obvious effect on the edge of ferromagnetic materials; Gradient value K of the normal component H(z) of leakage magnetic field in the specimen, as a parameter evaluation of stress concentration in the specimen, has high reliability in areas without correlation effect, but it has no credibility in areas under dual defect correlation effect. Moreover, this article also discusses the influence of measured path and the lift-off value on magnetic memory signals.

Introductions

Magnetic memory testing method as a new nondestructive testing technology has received the attention of scholars both at home and abroad [1-2]. The method, based on the principle of stress-magnetization effect on ferromagnetic components, that is, under the action of working load and geomagnetic field, the magnetic domain organization will orientate in a irreversible way, thus forming magnetic flux leakage in stress concentration zone, is used to locate early injured parts with the main characteristics of stress concentration of the ferromagnetic components by examining the magnetic flux leakage [3]. The essence of stress magnetization effect law is the magnetization law of component caused by stress. It mainly studies the magnetic flux leakage distribution caused by the tensile stress and other stress load under the action of magnetic field [4-5]. At present, the technology research mainly focuses on the basic experiments of testing mechanism. However, little is explored on the numerical simulation study of the testing mechanism.

Based on the principle of stress-magnetization effect of ferromagnetic components [6], with force-magnetic coupling finite element analysis of the 20# steel under external stress and ground magnetic field conditions by using the finite element simulation software (ANSYS). The distribution law of magnetic memory signals of the surface air layer and the distribution law of internal stress of dual defects specimens are given. The credibility of normal component gradient K value of the magnetic flux leakage as stress concentration evaluation parameters is examined. And the influence of measured path and lift-off value on magnetic memory signals is also discussed.

Coupled field principles

Coupled field analysis considers interaction and coupling of two or more disciplines in the process of the finite element analysis [7]. Sequential coupling method consists of two or more analysis carried out by a certain sequence, every kind of analysis carried out in different physical environments. By applying the previous results as the load to the following analysis, the coupling of two different physical fields is realized.

Numerical simulation analysis metal magnetic memory testing technology mainly considers the influence of stress on magnetic flux leakage of ferromagnetic components, while the magnetic field effect on the stress is very small, even negligible. So the ANSYS simulation analysis adopts sequential coupling numerical simulation analysis that combines structure static analysis and static magnetic analysis.

Numerical simulations

To contain the V-shaped and semicircle notch for the dual prefabricated defects of 20# steel as the research object, specimen sizes and main technical parameters are shown in Fig.1. Respectively, to extract the magnetic flux leakage form the specimen surface in path A, B, C, D and E, where is apart from the notch tip of 0mm, 2mm, 4mm, 6mm and 8mm, and the specimen thickness is 3mm.

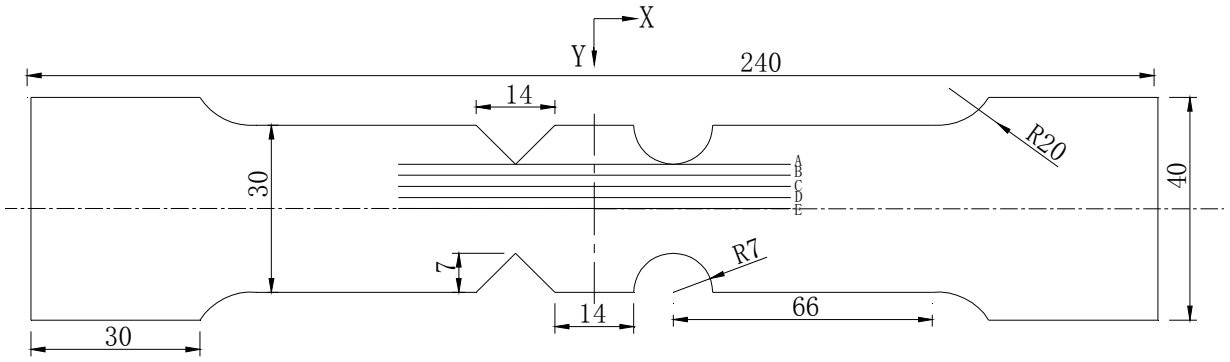

Fig.1 Specimen sizes of dual defects

Table 1 Main technical parameters of 20# steel

Parameters	E(GPa)	Poisson's ratio	σ_S(MPa)	μ_t
Value	203	0.28	235	285

Given the sample is symmetrical, in order to save computing time, computer hardware resources and to ensure the accuracy of the condition, a 1/2 modeling under test conditions is adopted. Due to the magnetic flux leakage of the external air layer need to extract, and analyzed the influence of the lift-off value, so thicker air layer model around the specimen is built. When dividing grid unit, method of manual control unit size and freedom divide is adopted, making the grid of ferromagnetic material area and the air layer area near prefabricated defects relatively dense and grid away from the prefabricated defects relatively sparse [8-9]. Specimen and air layer finite element mesh model as shown in fig.2 and 3, respectively.

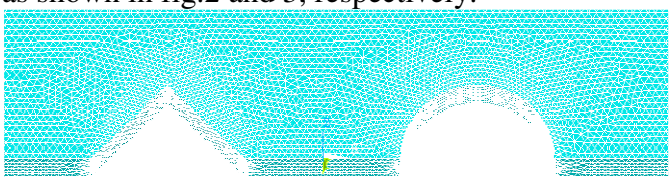

Fig.2 Finite element models of specimen

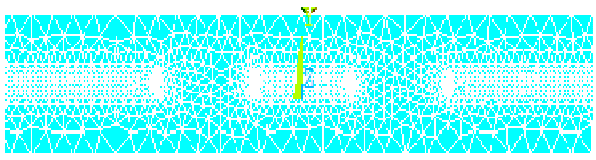

Fig.3 Finite element models of air layer

The simulation analysis is divided into static analysis and static magnetic analysis. In static analysis, displacement constraints and tensile load are respectively imposed on symmetric plane and about face of the model. These two different tensile loads are then written to load step, making it possible to carry out nonlinear static analysis under the condition close to real experiment. In static magnetic analysis, by applying a 39.8 A/m size of external environment magnetic field, the size of the earth's magnetic field on average, direction along the specimen with the X axis (see Fig.1). The magnetic flux leakage values of the path A, B, C, D, E, and different lift-off values is extracted by using APDL parametric program of ANSYS. As a result of the magnetic scalar potential method simulation, so the magnetic flux parallel boundary automatically satisfied, without human input.

Results

Stress distribution

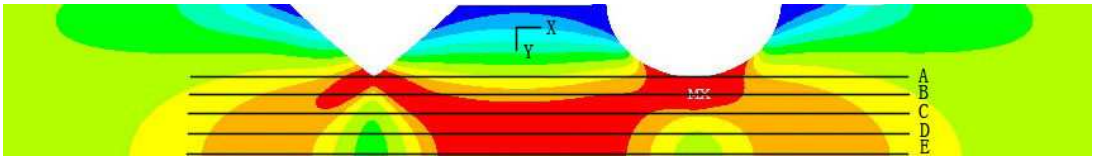

Fig.4 Contours of the internal stress distribution at F=150MPa

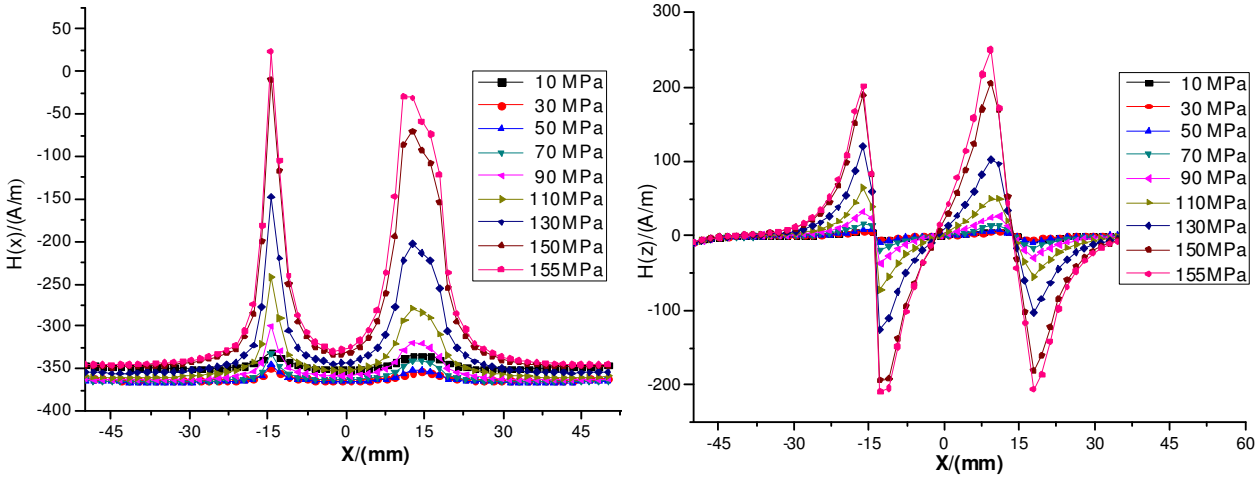
Nonlinear static analysis in ANSYS post-processing stage, contours of the stress distribution inside the specimen is obtained, which showed in fig.4. The simulation results show that: near the notch tip and corresponding position, V-notch and semicircle notch all show that the stress concentration phenomenon, which is the red area in the contours of the internal stress distribution. As can be seen from the contours, the width of the semicircle notch is slightly larger than the width of V-shaped notch; Along the Y axis from notch tip position, the stress concentration at the tip of V-shaped and semicircle notch significantly lower. In the specimen center along the Y axis, stress concentration significantly increased, appeared similar near the notch tip stress concentration phenomenon, and the range is bigger than the notch tip. Accordingly, gap shape also affects degree of the stress concentration and distribution. As a conclusion, with correlation effect of dual defects, the stress concentration is more obvious in the central of specimen than in the notch tip, leading to the specimen fracture more easily, with greater potential danger.

Magnetic flux leakage distribution



(a) Tangential component H(x) (b) Normal component H(z)

Fig.5 Size of magnetic flux leakage changing with tensile stress at h=1mm, path A

Figure 5 is the distribution curve of tangential component H(x) and normal component H(z) with the average stress by 20MPa ladder loaded, where is lift-off h=1mm from the surface of the specimen and path A (close to the edge of the specimen). Simulation results well accord with metal magnetic memory testing technology of detecting characteristics, namely in the stress concentration area, the tangential component H(x) of magnetic flux leakage has a maximum value, and the normal component H(z) of leakage magnetic field shows to change sign and a zero value. The figure shows that different notch, the peak-peak height and width of the magnetic memory signals have different values. The tangential component H(x) of V-shaped notch is higher, but the narrow; the tangential component H(x) of semicircle notch is weaker, but wide. The normal component H(z) of V-shaped notch is weak and semicircle notch is wide. The simulation results show that the stress concentration degree of different notch is different; also, there isn't any stress concentration in the area between two gaps. As shown in the leakage magnetic field value of path A, multi-defects correlation effect doesn't produce any stress concentration at the edge of the specimen, hence basically no effect on the edge.

In the actual detection, due to various factors such as interference of outside magnetic field, the use of the tangential component of the magnetic field and the normal component to determine the stress concentration is limited, prone to misjudgment and false negatives. Therefore, GB/T

26641-2011 "General NDT magnetic memory testing" puts forward it is recommended to use normal component of the magnetic field intensity gradient K value as a characteristic judgment.

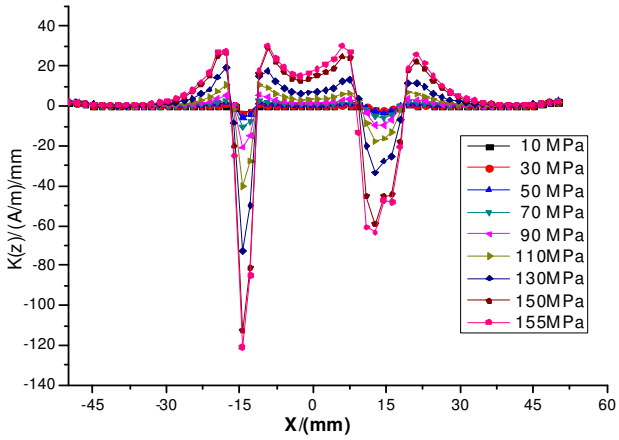


Fig.6 Normal component H(z)

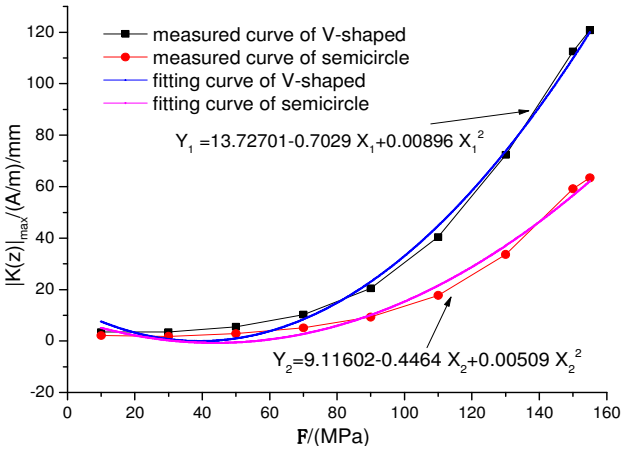

Fig.7 Maximum gradient of absolute value

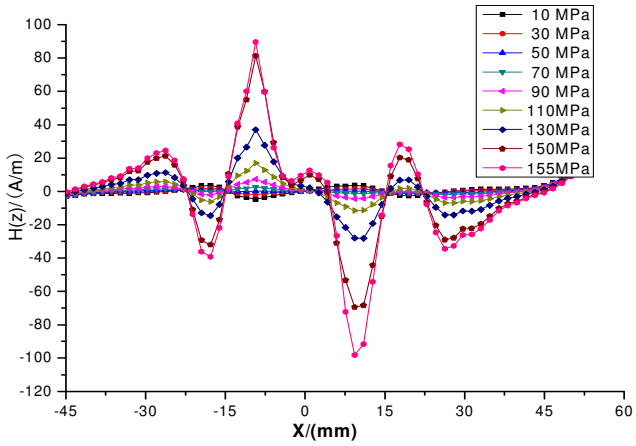
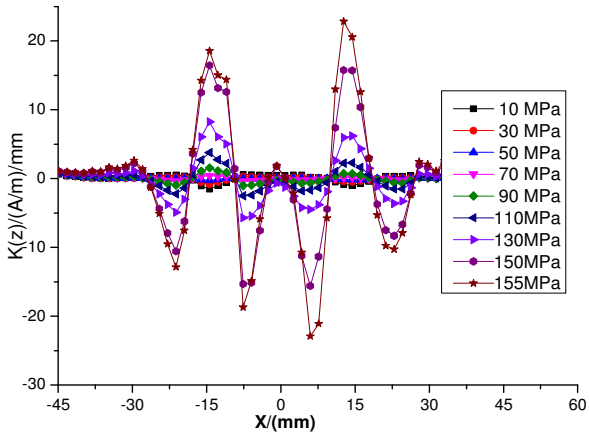
Figure 6 is the distribution curve of normal component gradient K on the edge of the specimen change with tensile stress. The figure shows that the gradient K peak-peak amplitude increases in reverse with the increase of stress on the stress concentration area. Also, it more clearly reflects the stress concentration degree and width. Figure 7 is the curve of maximum gradient of absolute value $|K(z)|_{max}$ change with tensile stress. From the fitting curve, the gradient K first increased slowly, and then increased obviously; |K(z)|max of V-shaped notch specimen increases rapidly than that of the semicircular notch specimen. V-shaped notch specimen is more sensible to stress and easier to be detected. The simulation results show that gradient K changes obviously with stress, and is free from interference of outside magnetic field and other factors. It can be concluded that gradient K of the normal component of leakage magnetic field in the specimen has high reliability in evaluation of stress concentration at the edge of dual defect correlation specimen or the non-associated region.



(a) Normal component H(z)



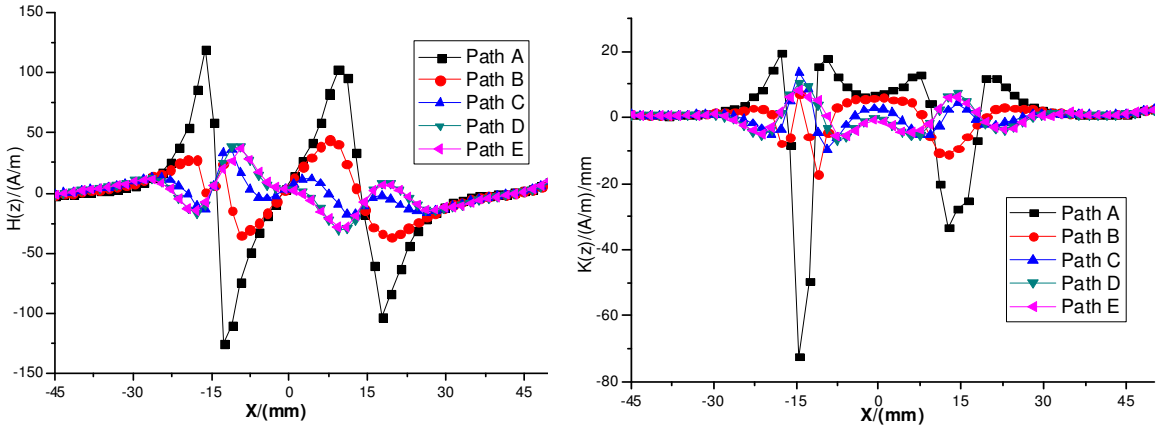
(b)Gradient K (Normal component)

Fig.8 Size of magnetic flux leakage changing with tensile stress at h=1mm, path E

To study the correlation effects of dual defects and the evaluation credibility of gradient K, obtained distribution curve of normal component H(z) and gradient K with tensile stress changes, where is lift-off value h=1mm from the surface of the specimen and path A (the centre of the specimen), shown in Fig.8. The figure shows that, with the increase of tensile stress, the normal component H(z) and its gradient K are increased gradually. As shown in the normal component H(z) of the specimen, along the X axis direction appears three different levels stress concentration areas with the characteristics of changing positive-negative symbols and having a zero in the maximum stress concentration zone. The degree of stress concentration at the centre of specimen is significantly greater than that of areas near notch top of the specimen. There appears displacement for the stress concentration on the X direction. Stress concentration at the center of the specimen significantly greater than V-shaped, semicircular notch near the tip, and the stress concentration area in the X direction to generate a displacement. However, in Fig.8 (b), the curve of gradient K

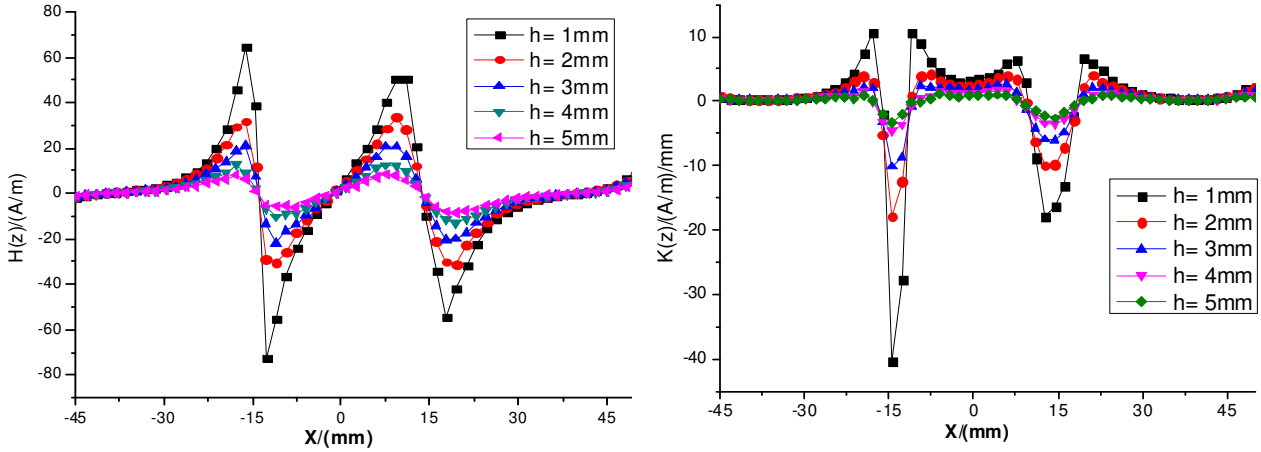
can be drawn from four stress concentration areas through the judgment characteristics of gradient K increasing reverse. Compare with the internal stress contours of the specimen (Fig.4), the results showed that: the correlation effect of dual defects produce more severe stress concentration phenomenon on the associated region of ferromagnetic specimen, and has important influence on specimen life; Gradient value K of the normal component H(z) of leakage magnetic field in the specimen, as a parameter evaluation of stress concentration in the specimen, has high reliability in areas without correlation effect, but it has no credibility in areas under dual defect correlation effect.

Influence of measured path and lift-off value



(a) Normal component H(z) (b)Gradient K (Normal component)

Fig.9 Size of magnetic flux leakage on different measuring path at h=1mm, F=130MPa



(a) Normal component H(z) (b)Gradient K (Normal component)

Fig.10 Size of magnetic flux leakage on different lift-off value at Path A, F=130MPa

Due to the magnetic memory signal is weak, and vulnerable to the interference of outside factors. In order to study the influence factors of metal magnetic memory testing signals and extract the normal component H(z) and the gradient K in the different measured path and the difference lift-off value on the surface of specimen, as shown in fig.9 and 10. From fig.9 shows that far from notch tip along the Y axis, the normal component H(z) peak-peak amplitude began to smaller in terms of exponential law and appear reverse changes in the path B. The magnetic field gradient K distribution can be seen from the more obvious results. The results show that different measured path, magnetic memory signal is not the same size and distribution, and further proved the validity of the gradient K evaluation characteristics. From fig.10 shows that with the increase of lift-off value, the normal component H(z) peak-peak amplitude began to smaller in terms of exponential law, and the gradient K is also more obvious. Simulation results show that: different lift-off value, the magnetic memory signal changes in the larger, has greater influence on the determination of stress concentration.

To sum up, the measured path and the lift-off value for the magnetic memory signals have a more significant effect. Therefore, in the use of metal magnetic memory testing technology practice

operation, should fully consider the measured path and the lift-off effect on the signal of metal magnetic memory.

Conclusions

(1) The correlation effect of dual defects produces more severe stress concentration phenomenon on the associated region of ferromagnetic specimen, and had no obvious effect on the edge of ferromagnetic specimen. It can be seen that the correlation effect of dual defects mainly affects specimen center area, making it more likely to rupture, thus shorten the service life of the specimen.

(2) Gradient value K of the normal component H(z) of leakage magnetic field in the specimen, as a parameter evaluation of stress concentration in the specimen, has high reliability in areas without correlation effect, but it has no credibility in areas under dual defect correlation effect.

(3) With the change of measured path and lift-off value, the normal component H(z) peak-peak amplitude began to smaller in terms of exponential law, and its gradient K is more obvious. Therefore, in the use of metal magnetic memory testing technology practice operation, should fully consider the measured path and the lift-off effect on the signal of metal magnetic memory.

Keywords: High and Low Gimbals; Temperature Control; Dahlin Algorithm; Smith Predictive Control Algorithm; Simulink

Abstract. In view of characteristics owned by high and low gimbals, for instance pure lag, large inertia, strongly nonlinear and so on, which was employed in low light level (LLL) weapon sight reliability detection system. The basic working principle and mathematical model of Dahlin and Smith predictive control algorithm were mainly researched. And ideal control curves were obtained by software emulation. The simulated results showed that the two algorithms each have their advantages, shortcomings and the proper situations, but as to improve the control efficiency of system, the Dahlin is superior.

Introduction

High and low temperature environmental simulation system is widely used in many fields, which plays an extremely important role in light weapon sight reliability test. Many algorithms are commonly used in the field of temperature control, but they are applied to different control systems considering of their advantages and disadvantages. Delay is inherent in industrial process, control issues of large inertia, pure time delay objects during industrial control process are universal existence. It is prone to encounter bigger overshoot, longer settling time and other problems, production process control quality will be affected to a great extent. For large time-delay system, a variety of combined algorithms are derived from conventional control algorithm, such as fuzzy control based on combined Smith predictor, fuzzy proportional integral derivative control (PID), adaptive compensation control and so on[1-6]. And during the course of the pure lag control system, Dahlin and Smith predictive control algorithm also be widely employed.

Establishment of Temperature Control Model

Temperature object suffers from big time constant, serious time-delay, flexible and complex influencing factors. In general case, temperature shows an exponential relationship with time. An analysis of main causes of time delay has been made as follows. Because heat transfer is a slow process and temperature element has a certain inertia, controlled temperature change is lag behind controller output[7]. Moreover, correlated analysis shows that the temperature control system has the following traits: weak adaptive ability, heating and heat preservation by means of power supply, using air cooling, so its temperature curve has characteristics of high peak overshoot and long stability time.

The results show that temperature control features of high and low gimbals are pure time delay, large inertia and nonlinear. Dahlin and Smith predictive control algorithm are both effective in controlling of the pure delay system. However, differences exist in the Dahlin and Smith predictive control algorithm. So it has important meanings to select better one to control the system by analysing of their advantages and disadvantages. According to the principles of thermodynamics, mathematical model of the controlled object as following shows:

$$G_0(s) = \frac{Ke^{-\tau s}}{TS+1} = G_P(S)e^{-\tau s} \tag{1}$$

Where K is the magnification, τ is pure delay time, T is process time, $G_p(S)$ is the part without pure delay in the controlled object. Close-loop transfer function can be expressed as:

$$G(S)=\frac{G_C(S)G_P(S)e^{-\tau s}}{1+G_C(S)G_P(S)e^{-\tau s}} \tag{2}$$

$e^{-\tau s}$ respects to lag link which would influence the stability of the system. The greater the $e^{-\tau s}$ is, the more unstable the system.

Research of Temperature Control Algorithms

There are many algorithms are applied to control temperature, among them Dahlin and Smith predictive control show great inhibitory effects on pure lag control system.

(1) Dahlin algorithm

The Dahlin algorithm was put forward in 1968. Its principle is: anticipant closed-loop response is designed as one step inertia adds delays, and then conversely obtains controller satisfied the closed-loop response. Control system block diagram as the Figure 1 below:

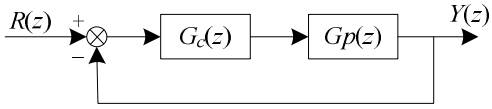

Fig.1. Single loop control system diagram

Where $G_C(z)$ is digital controller, $G_P(z)$ is controlled object.

Transfer function is given by:

$$\phi(s)=\frac{Y(s)}{R(s)}=\frac{e^{-\tau s}}{T_\varphi s+1} \tag{3}$$

Where T_φ is the time constant of the closed-loop system.

Dahlin algorithm has good control effect on pure delay system.

(2) Smith predictive control algorithm

Smith predictive control system structure diagram as shown in Figure 2:

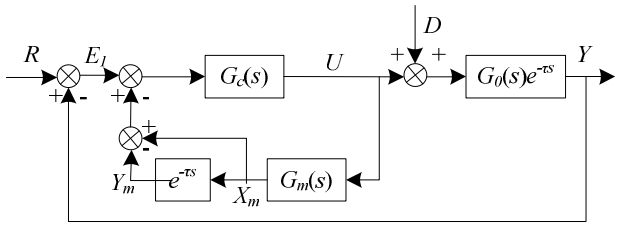

Fig.2. The equivalent figure of Smith predictive control system

The transfer function of system with delay time as shown in Formula 2, and the characteristic equation can be represented as:

$$1+G_C(s)G_0(s)e^{-\tau s}=0 \tag{4}$$

Smith compensation controller is added to overcome the instability of the system caused by the pure delay time (τ) , the closed loop transfer function of the system can be expressed as:

$$1+G_C(s)G_0(s)=0 \tag{5}$$

The influence of pure time delay on system stability can be well controlled.

Simulation based on Simulink

According to the transfer function (Formula 2), we can take on the value K=1.5, τ =80, T=2000, so reference model for the control system can be written as:

$$G_m(s)e^{-\tau s}=\frac{1.5}{2000s+1}e^{-80s} \tag{6}$$

A. Buildup of simulating model for the system

The maximum output temperature desired in the experiment is 70 ℃. Then simulation to the system was carried when the input was a step function. Corresponding principle block diagrams established in the Simulink as shown in Figure 3 and 4:

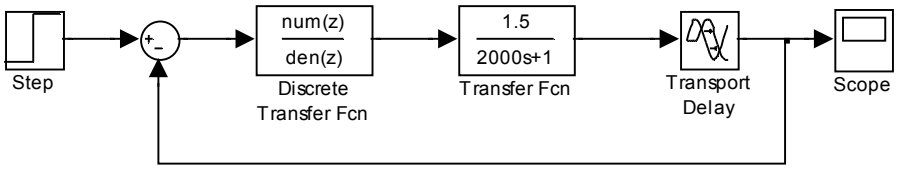

Fig.3. The simulating schematic diagram based on Dahlin algorithm

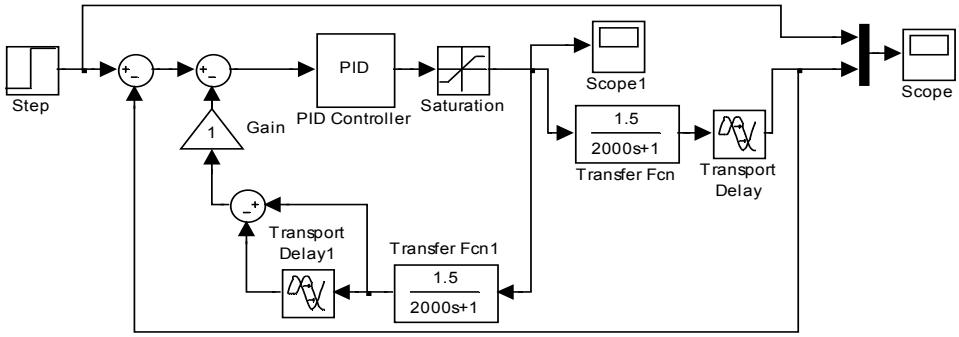

Fig.4. The simulating schematic diagram based on Smith predictive control algorithm

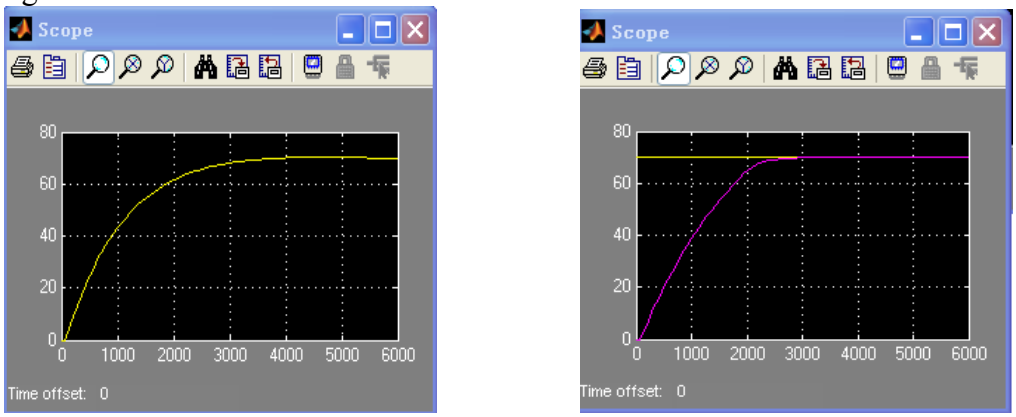
B. Results and discussion

The algorithm was proposed, through analyzing the simulation curves of the two algorithms in different condition, which was more suitable for the temperature control system. The Smith predictive control involves a proportional integral control (PI), where the proportional factor $k_p = 4$, integral coefficient $k_i = 0.007$. (Abscissa is time: s; Ordinate is temperature: ℃)

(1) When two control models are optimally matching with system model, simulation curves are illustrated in Figure 5.



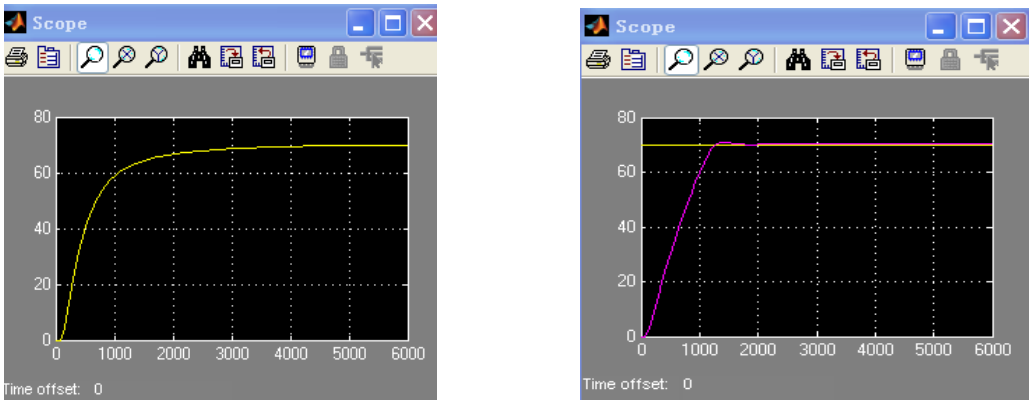
(a) Dahlin algorithm (b) Smith predictive control algorithm

Fig.5. Step response curves based on the two algorithms

As seen from above simulation results, both of them have no steady state error, but Smith predictive control algorithm is relatively ideal, which has fast response to the setting with compare to Dahlin.

(2) When two control models and system model are mismatching, simulation results are shown in Figure 6. Let K=2, τ =110, T=1600, reference model of the control system is given by:

$$G_m(s)e^{-\tau s} = \frac{2}{1600s+1}e^{-110s} \tag{7}$$



(a) Dahlin algorithm (b) Smith predictive control algorithm

Fig.6. Step response curves based on the two algorithms

The Figures illustrate the difference behavior of two controllers under the same situation for the specific set points:

Response time: Smith predictive control algorithm appears to have fast response for setting value in comparison with Dahlin algorithm.

Overshoot: Due to the fast response, the Smith predictive control algorithm has positive overshoot. In contrary, overshooting is hardly observed in the experiments of the Dahlin algorithm. Oscillation can be eliminated using Dahlin arithmetic, which is caused by model error. And it makes the system have better stability, adaptability and control precision. The Figures reflect that both of algorithms are suitable for the pure delay system. But compared with the Smith, the Dahlin is more stable and has better effect.

Conclusion

On the basis of analysis of temperature control features of high and low gimbals, this paper mainly studied the control effect of Dahlin and Smith predictive control algorithm which are common algorithms for pure lag control system. It can be concluded that the Dahlin algorithm is more stable, despite its slow response speed. This algorithm suitable for the system which have no or less super adjusting and do not require high rapidity demands. Smith predictive control algorithm has unique advantages in temperature control system. However, it still need to be improved furtherly. Certainly, there are many more effective and advanced algorithms exist in many practical applications of the pure delay system. This article mainly discussed the general characteristics and differences of the two algorithms.

Keywords: Noise; NPD Database; Static Prediction

Abstract. According to the method described in Technical Manual of Aircraft Noise Evaluation Procedures, this system can predict the EPNL (Effective Perceived Noise Level) of aircraft take-off, approaching and side boundary. The system also contains the function of managing andcalling NPD database, and can assess the predictive value basing on the noise stringency curve. This saves a number of cost for the airworthiness certification of aircraft noise, and is a new engineering practice which has a good application value.

Introduction

The technology of aircraft noise predictions is already mature in Europe and America. Completed aircraft noise prediction systems have been built, and the measurement criterions, methods, steps and procedures have been included in the corresponding technical manuals. But the results of research have been always in a state of blockade to China, and the training costs are too expensive. The domestic standards or guidelines about the flight noise prediction according to the static test data are not completed, researches on aero-engine noise airworthiness are still in the infancy.

The static prediction, as an alternative method for airworthiness certification of aircraft noise, is to predict aircraft noise level by using aero-engine static far-field noise measurement data. This paper shows a particular algorithm which outputs the noise value for the flight state by measuring the engine noise data under static conditions. The results can be compared with the NPD data of the corresponding aircraft, the algorithm is available if the error is within the acceptable range [1].

Prediction principles and procedures

The prediction procedure includes：build NPD database；select the appropriate methods to correct for static data according to the main correction factor，acquire static test data mapping to third-octave 24 center frequency corresponding sound pressure level in flight; calculate the effective perceived noise level under certain conditions according to CCAR36; compare the results to the NPD data.

The construction of NPD database

After a sufficient number of noise measurement，the noise-power curves of lateral and fly-over noise for certain distances can be made. Expand these curves in a certain distance by calculating or using additional flight test data, to form a generalized noise database. This database which is used for "flight data" and noise certification of derivative models, commonly referred to the NPD[2]。

During the airworthiness certification process of a certain type of aircraft noise, NPD noise test is conducted. Select the appropriate noise measurement points according to the circumstances of the airport runway of flight test and environmental climate. When the test site, test instruments and equipment as well as test day atmospheric conditions meet the requirements of the flight noise, the test of aircraft noise begin, to obtain NPD data. Aircraft noise certification procedures specified that for the noise certification, the measurements of noise level of approach, lateral and take-off are mandatory. And there are strict requirements about the locations of the measurement points. As is shown in figure 1,the noise measurement reference point for approach is located in the extended

runway center line at 2000m from the runway threshold, the noise measurement reference point for take-off is located in extended runway center line at 6500m from the start point of take-off, the lateral noise measurement reference point is located in the sideline which is parallel to and 450 meters from the extended runway center line, where the maximum noise level is measured after take-off.

In each case of takeoff thrust(power) including a full thrust and reduced thrust (power), the aircraft flies over the lateral and fly-over sensor according to the program. The figure 2 shows the programmed flight path of take-off measurement, in which the point C is the equivalent entry point. The aircraft maintains a constant height from point A to point B, continues to climb from the beginning of point B, climbs at a constant angle from the point C, intersects the takeoff reference flight path intersection continues until the end of the reference trajectory takeoff noise assessment. The point D is the theoretical take off launch point, to establish referencetrack, and it will be the point E with reducedthrust. The point F is the end point of takeoff flight path for noise assessment. When approaching, the aircraft normally covers the planned flight path and maintains a stable configuration and power until the PNLTM 10dB reduction. The aircraft then continues to circle without landing.

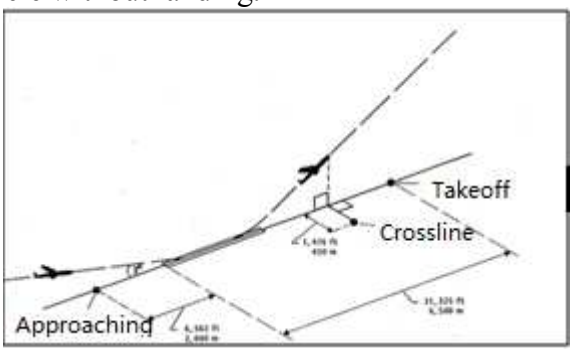

Fig.1 Reference Track Procedure

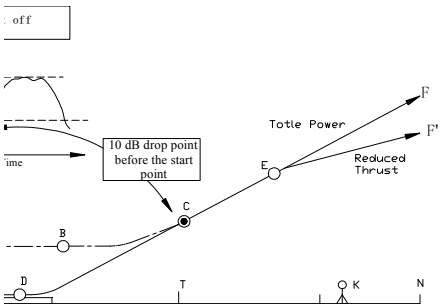

Fig.2 Cut-in Flight Procedure

Then we fit the data into the NPD curve with Matlab, the noise level calculated with NPD data interpolation method is the reference noise level, it is available only for infinitely long flight path with constant power under the ideal conditions. The corrections of influence factors in the actual environment are necessary aiming at the finite length path which is concerned in the noise certification, such as non reference velocity, engine mounting influence (lateral), the sideline attenuation. Furthermore, the noise NPD database is established.

The correction of static data and the calculation of effective perceived noise level

Map the static testing data to the sound pressure level which is corresponded to twenty-four a third octave center frequency. There are many factors to be modified while mapping these data from static to flight status. Here we mainly considerated are as followed: the correction of mobile noise resource, the correction of outside airplane structure, the correction of noise influenced by wind speed and the sound attenuation.

The appendix 16 in ICAO mentions that the essential element of noise qualified approval criteria is the measurement standard of noise assessment which is called effective perceived noise level and is unit of dB. EPNL is a numerical evaluation of the human subjective influence of airplane noise, which is composed of instantaneous perceived noise level which has been modified by the frequency spectrum irregular correction and sustaining time correction. In order to determine the value of EPNL, it is required to calculate the instantaneous sound pressure level in twenty-four a third octave every 0.5 second in the process of airplane noise testing. Then induce the effective perceived noise level (i.e. EPNL) to evaluate human's subjective reaction with all the noise physical quantities. There are five following steps [3]:

a) Convert the sound pressure level of twenty-four a third octave into the perceive noise values referring to the sonar table and combine these noise values into instantaneous perceived noise level named as PNL(k);

b) Calculate the pure tone correction named as C (k) for every frequency spectrum;

c) Add the pure tone correction to the perceived noise level and will gain the pure tone perceived noise level named as PNLT (k) in every half a second increment.

$$\mathrm{PNLT}(k) = \mathrm{PNL}(K) + \mathrm{C}(k)$$

Then induce the instantaneous value of pure tone correction perceive noise level and determine the maximum value named as PNLTM.

d) Through integrating of pure tone correction perceive noise level and time relation curve we can compute the sustaining time correction called D;

e) Algebra add the maximum pure tone perceived noise level to the sustaining time correction and gain the effective perceived noise level named as EPNL, namely

$$\mathrm{EPNL} = \mathrm{PNLTM} + \mathrm{D}$$

The Verification of Computing Result

Compared the computing effective perceived noise level with the NPD database in corresponding airplane's type, compute the error and portray the noise stringent curve and finally verify its accuracy.

The System of Noise Prediction

Introduction to Prediction System

The system of noise prediction is based on the software platform of SQL Server2008 and visual C++2010 in visual C++2010 compiling environment where the routine at the front desk is compiled with Frame MFC and the backend database is built with SQL Server 2008. The system consists of user management module, data management module, core calculation module, airworthiness assessment module and evaluation result output module and so on.

The exploit steps of the static testing prediction system are as follow:

1) Establishing the NPD database and the static testing database with the SQL platform;
2) Compiling the main structure of the software with visual C++2010 language;
3) Establishing the interface to input the initial condition data of static testing and compiling the procedure code of modifying factors algorithm;
4) Establishing the link with the static testing database and compiling the procedure code of calculation and display;
5) Deriving the modified data;

Read-in data through the software of calculating EPNL and you will get the corresponding EPNL value. Comparing the value with the original database and there is a difference value named Δ. Add the obtained value to the difference value is the NPD value of the derived airplane.

Static prediction calculation example

This example is based on static data engine test data obtained from measurement and aircraft company to predict aircraft approach noise level. Use of the noise prediction system described in this paper is demonstrated as follows:

Enter the user name and password, login noise prediction system.

NPD database calls and static data correction.

First of all, import previous NPD data into NPD database. For example, the 3JT8D engine EPNL is 100.7dB under the condition of distance 630 and the thrust of 3000.

Input Maher number, engine number, the aircraft flight data approved, reference wind speed, temperature, humidity, maximum take-off weight parameters into the reference parameter input interface. The system will correct the parameters of the static test data and the reference data mainly considering the correction of noise source mobile, correction of the shape and structure of aircraft, correction of noise with the wind speed and noise attenuation. It can respectively get the modified value of noise source mobile is 25.739dB, airframe noise correction value is -30.103dB, shape correction is 4.771dB, geometric divergence attenuation calculated is -8.519dB, also can calculate the attenuation caused by atmospheric absorption.

Fig.3 Reference Parameters Input

3) Calculation the EPNL by the revised data.

Prediction software can calculate the effective perceived noise values in different stages of the aircraft take-off, approach, lateral, and intuitively output the parameters in the calculate process, such as instantaneous perceived noise level PNL (k), the maximum value of PNLTM, as shown in Figure 5, figure 6. The predicted value is finally evaluated according to the noise strictly curve, as shown in figure 7.

The calculated EPNL of prototype airplane is 96.990dB, EPNL of derivative aircraft is 97.758dB. According to the formula:

$$\mathrm{NPD}_{\mathrm{Modification}} = \Delta\mathrm{EPNL}_{\mathrm{Prototype}} + \mathrm{EPNL}_{\mathrm{Modification}}$$

Substituting the data available:

$$NPD_{Modification} = (100.7\mathrm{dB}-96.990\mathrm{dB})+97.758\mathrm{dB}=101.468\mathrm{dB}$$

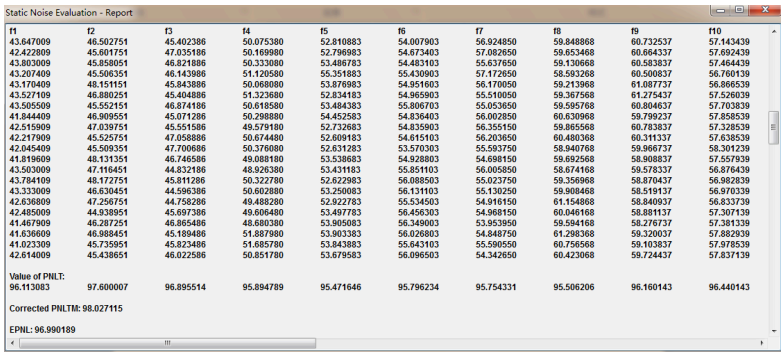

Fig.4 Prototype Engine Three Octave Sound Pressure Level after Correction

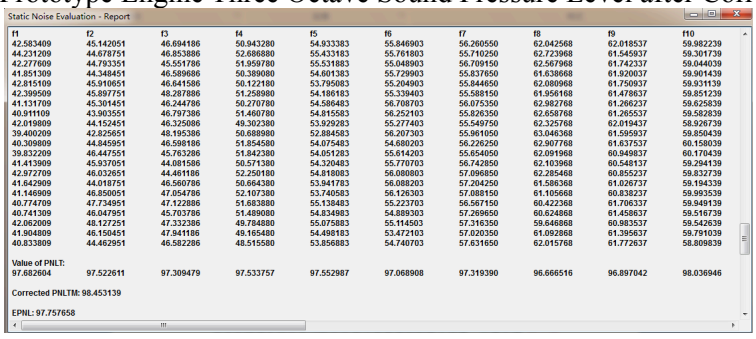

Fig.5 Derivative Engine Three Octave Sound Pressure Level after Correction

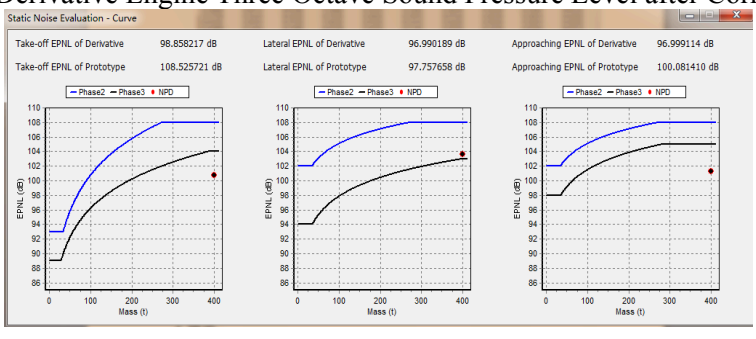

Fig.6 Prototype and Derivative Flight Effective Perceived Noise Level EPNL

There is a slight error between the real value 98.7dB and the calculation value, because the correction factors are not considered in the prediction system development process. But it's less than 3 dB and in the standard allowable range [4]. According to prototype the NPD data extrapolation noise to the examination and approval of qualified stipulated in the distance, under the thrust of feeling noise effectively, and according to the requirements of aircraft noise certification assessment, so as to provide a basis for validation of aircraft noise airworthiness.

Conclusions

Static prediction system introduced in this paper is of high speed, large capacity, saving features high accuracy, which can effectively reduce the redundant computation in the noise airworthiness certification process, improve accuracy and reduce the error, simplify noise airworthiness certification program and greatly reduce the derived type machine's noise certification costs. At present, the development of China civil aviation industry is in the key period. As well as a pioneering attempt in the domestic and the results also show that the attempt is successful.

Keywords: Unbalance Vibration; EMD; Time Field; Signal Separation

Abstract. It is the premise conditions of dynamic balance monitoring and control technology that the unbalance vibration signal is separated accurately. Based on the theory analysis of EMD (Empirical Mode Decomposition), the time field method of unbalance vibration signal separation is proposed. The basic principle is that the reference signal and radial vibration of rotor must be simultaneously measured, and then the IMF(Intrinsic Mode Function) components are separated based on the EMD method. The time field signal of unbalance vibration can be identified by comparing the IMF's frequency with rotational frequency. The method effectiveness has been proved by experimental data analysis.

Introduction

The unbalance is one of the key problems which limit the machinery industry development. In order to solve the unbalance problems, the unbalance vibration signal must be separated accurately. Usually, many harmonic components are hidden in the rotor vibration signal, and some special reasons are directly related with those harmonic components, however the unbalance vibration component is only related with rotating frequency. Based on the principle, the relative studies are concentrated on signal filtering and noise reduction based on FFT method. The practice shows that the frequency and phase error of the separated signal are large based on frequency field analysis method. The EMD is driven by data itself and belongs to the time field method. The advantage of EMD is obvious when it applied to analyze the nonlinear and nonstationary signal [2]. The unbalance vibration signal separation method based on EMD is discussed in the paper.

The theory of EMD

The EMD method was firstly proposed by Norden E. Huang in 1998 [3], and the essence of EMD is to decompose adaptively signal. A series of IMF are supposed at first, and the IMF must meet two basic conditions: (1) On whole data series, the difference between extreme points and zero-crossing points must be zero or one point. (2) The mean of envelope curve, which formed by local maxima and local minimum, is zero at any time points. Based on the assumption, any signal can be decomposed to many IMF components, and the decomposition steps of EMD are as follows [3]:

(1) All the maximum points of signal X (T) must be found firstly, and then the upper envelope curve of original data sequence can be interpolated by spline function and denoted as $m_u(t)$.

(2) All the minimum points of signal X (T) are found secondly, and then the lower envelope curve of original data sequence can be interpolated by spline function and denoted as $m_u(t)$.

(3) The average envelope curve can be obtained by the mean of upper and lower envelope curve and denoted as $m_1(t)$. The equation can be expressed as follow:

$$m_1(t) = \sum_{i=1}^{n} [m_u(i) + m_d(i)] / 2 \qquad (1)$$

In the equation 1, n is the data length. The new data series $h_1(t)$ can be obtained by subtracting the average envelope curve $m_1(t)$ from original data series X(t). The equation is expressed as follow:

$$h_1(t) = X(t) - m_1(t) \quad (2)$$

The data series $h_1(t)$ is the first IMF component if it satisfies the IMF conditions.

(4) Otherwise, we can take $h_1(t)$ as the initial data and calculate the new average curve $m_{11}(t)$ by repeating step1~3, and then the new data series $h_{11}(t)$ can be calculated by $h_{11}(t)=h_1(t)-m_{11}(t)$. If $h_{11}(t)$ doesn't satisfy IMF conditions, we can repeat the above steps for k times until the data series $h_{1k}(t)$ satisfies IMF conditions, and the $h_{1k}(t)$ is calculated by $h_{1k}(t)=h_{1k}(t)-m_{1k}(t)$. Now we record $h_{1k}(t)$ as $C_1(t)$ and take $C_1(t)$ as the first IMF component of X(t).

The whole disposition process is just like a sieve, and the finest IMF component can be decomposed through this sieve step by step. In order to make sure the amplitudes and frequencies of these IMF components have some definite physical meanings. The appropriate stopping criterion is essential to limit screening time. The criterion of simulating Cauchy convergence was provided by Huang etc in which the standard deviation (SD) of mode component $h_{lk}(t)$ and $h_{l(k+1)}(t)$ could be calculated and the definition of SD is as following [3]:

$$SD = \sum_{t=0}^{T} \left[\frac{\left| h_{1k}(t) - h_{1(k+1)}(t) \right|^2}{h_{1k}^2} \right] \angle \varepsilon \quad (3)$$

In the equation 3, T is the signal length. The screening process will stop when SD is less than ε, and the value of ε ranges from 0.2 to 0.3.

(5) The new data series $R_1(t)$ can be gained by subtracting $C_1(t)$ from X(t) .

$$R_1(t) = X(t) - C_1(t) \quad (4)$$

The IMF component $C_2(t)$ will be decomposed by taking $R_1(t)$ as the initial data and repeating steps 1~4. Repeat the above steps p times until no IMF component can be separated. The p components and remains E_p of the initial signal X(t) will be discomposed, and then signal X(t) can be showed as:

$$X(t) = \sum_{i=1}^{p} C_i(t) + E_m \quad (5)$$

It can be seen from above dispose progress, the nonlinear and nonstationary signal can be decomposed to linear and stationary data series based on EMD method. The IMF component, including only one frequency component, can be applied to identify the unbalance vibration signal.

The unbalance vibration signal separation for rotor based on EMD method

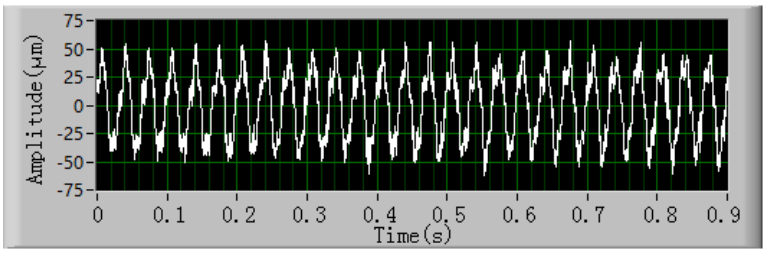
In theory, the unbalance vibration frequency equal to rotating frequency. The EMD principle indicates that it is driven by data itself and the most refined component can be separated. Therefore, the unbalance vibration signal of rotor can be separated by combining EMD method with the rotating frequency. In addition, in order to obtain the phase of unbalance vibration signal, the reference signal and radial vibration signal of rotor must be collected synchronously. The application step of the method is as follows:

Firstly, the original vibration signal should be decomposed by EMD method, and all the IMF components of the signal are separated.

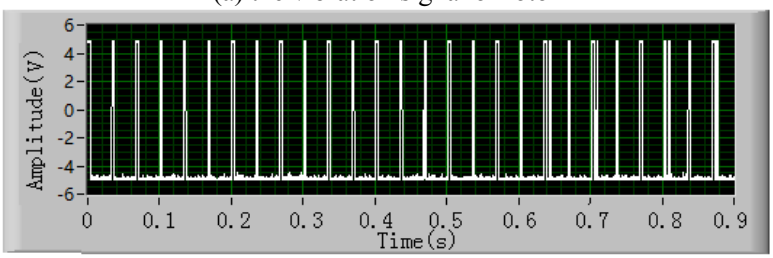
Secondly, the frequency feature of each IMF components is analyzed, and then the unbalance vibration component is identified by comparing with rotating frequency.

Thirdly, considering of end effect，the middle and no contamination part of the IMF data series are intercepted as the effective data[4].

In order to test the validity of method, the monitoring signal from rotor vibration experiment is analyzed in the paper. The vibration signal and reference signal are shown as figure 1. The testing speed is 1800 r/min, the sampling frequency is 10 kHz, the sampling length is 9000 points.



(a) the vibration signal of rotor



(b) the reference signal of rotor

Figure 1. The monitoring signal of rotor

The IMF components of vibration signal in figure 1(a) can be decomposed based EMD method, and then the power spectrum of each IMF component is estimated. For example, the IMF5 to IMF8 and their power spectrums are shown as figure 2. In figure 2, the data series from 1000 to 5000 of IMF component is displayed.

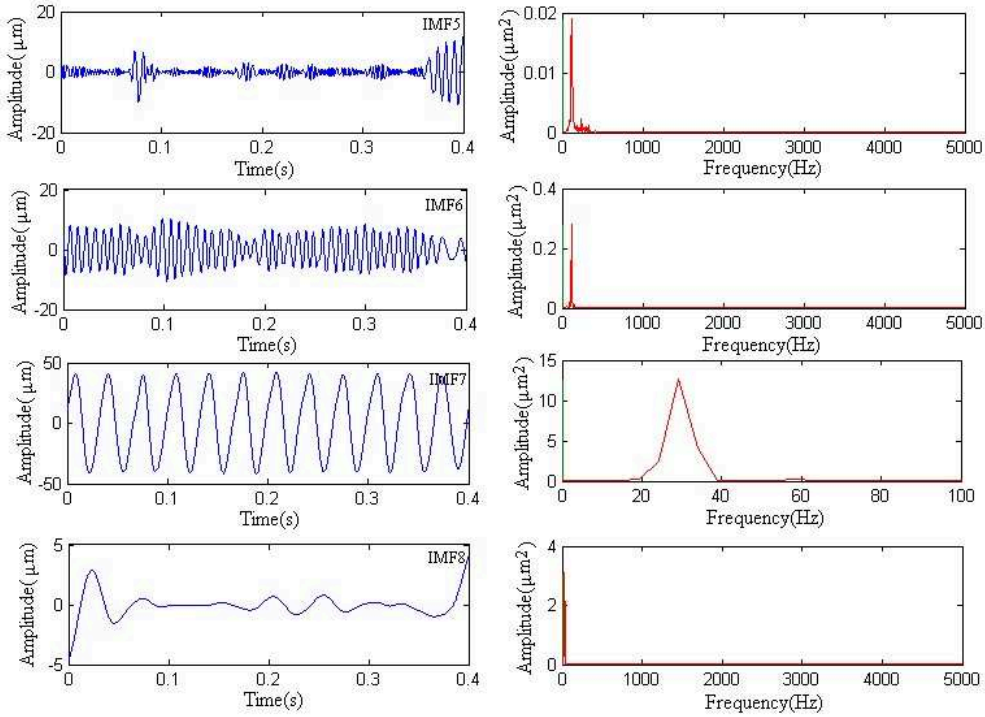


Figure 2. The IMF components and their power spectrum

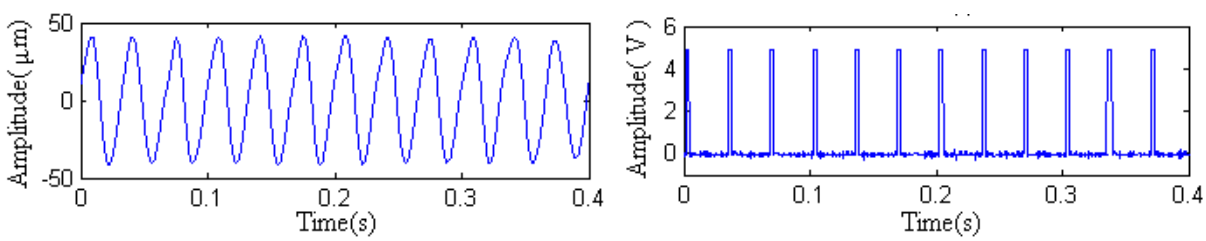
It can be seen from figure 2, the frequency of IMF7 is about 30Hz (equal to rotating frequency). So the IMF7 can be taken as the time field signal of rotor unbalance vibration. The IMF7 and corresponding reference signal are shown as figure 3.



(a) The unbalance vibration signal (b) The reference signal

Figure 3. The unbalance vibration and its reference signal

The amplitude of unbalance vibration signal can be obtained from figure 3(a) as 41.62μm. Meanwhile, the phase of unbalance vibration signal can be obtained by analyzing the discrete data series of figure 3. The method is as: the position corresponding to the first positive peak value in figure 3(a) is found as N1 (=97), and then the position corresponding to the first pulse rising time figure 3(b) is found as N2(=5). Combined with sampling frequency (denoted by sf) and rotating frequency (denoted by sf) message, the phase of unbalance vibration signal can be calculated as follow equation.

$$\alpha = \frac{N2 - N1}{sf / rf} \times 360^o = \frac{5 - 97}{1000/3} \times 360^o = -99.36^o$$

In order to test the accuracy of the separated signal, the sine function is constructed by the rotating frequency (30 Hz) and unbalance vibration vector($41.60\angle -99.36^o$), and then the residual signal can be obtained as figure 4 shows by subtracting the sine function from the original signal in figure 1(a).

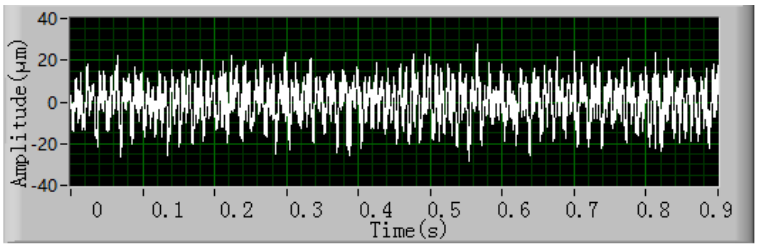


Figure 4. The residual vibration signal

It can be seen from figure 4, the amplitude of the residual vibration signal is decreased obviously, and the periodicity of the signal is not obvious. It proves that the unbalance vibration component in rotor original vibration signal has been eliminated, and the EMD method is effective for the rotor unbalance vibration signal separating.

Conclusion

Based on EMD principle, the method for rotor unbalance vibration signal separating is proposed in the paper. The experimental data analysis indicates the separating accuracy is high, and the amplitude and phase message can be obtained based on the time field signal analysis. The method can be applied in the rotor unbalance vibration condition monitor and the dynamic balance field.

Keywords: Rapid prototyping; Product development; Optimization design

Abstract. The rapid prototyping technology was introduced, including its definition, principle and characteristics. The advantages of rapid prototyping technology in new product development were analyzed. Application of rapid prototyping technology in design of mechanical parts, industrial model, medical model, ceramic products, automobile model and products based on ergonomics was discussed. The feasibility of rapid prototyping technology in product design and the optimization direction was prospected.

Introduction

Rapid Prototyping (RP) technology is developing in recent years as a new manufacturing technique. It is a major breakthrough in the field of manufacturing technology in recent years. Rapid Prototyping technology can meet the needs of the modern manufacturing technology development, because of its fast developed in the manufacturing industry, biological engineering, etc[1]. At present, RP technology has got the attention of the industry, especially in household appliances, automobiles, toys, light industrial products, building models, medical devices and artificial organs, spacecrafts, military equipments, archaeology, industrial manufacturing, sculptures, film production, and engaged in CAD department, and many good application cases have been made [2,3].

In product design, test analysis and performance evaluation of the product design were carried out based on rapid prototyping, which can shorten product development cycle and reduce design cost. After years of development, Rapid Prototyping technology is not limited to the original sense of the concept "prototype", it has fast developing toward rapid parts, rapid tools, etc. The research in product optimization design based on Rapid Prototyping, however, has not developed yet. In this paper, application of rapid prototyping in the product design was discussed, and research direction of Rapid Prototyping technology in product optimization design was prospected.

Rapid prototyping technology

Rapid prototyping technology involves the CAD, CAM, CNC, precision servo drive, optoelectronics, and new materials technology, etc. According to the structure of product 3D CAD model, layered slices and outline of each section was obtained. According to the outline, selective laser jets, solidifying liquid resin (or cutting layers of paper, or sintering powder material layers), or the injection source selectively spraying layers of binder or hot melt material, form the cross section, gradually accumulating into a 3D product.

Compared with the traditional processing methods (removing material and deformation method), the processing method of rapid prototyping technology is the material accumulation method, rapid prototyping processing principle is shown in fig. 1.

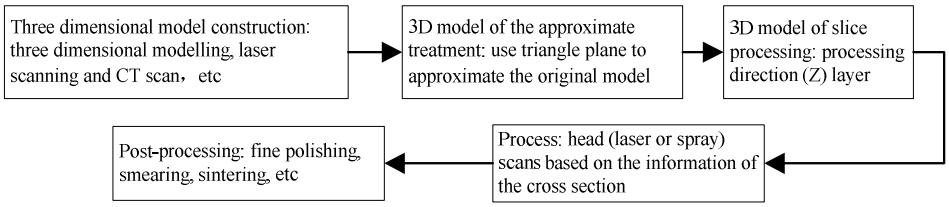

Fig.1 Rapid prototyping processing principle

The advantages of rapid prototyping in product design

Rapid prototyping processing principle and the traditional processing principle are different. The differences are shown in table 1.

Table 1 Difference between rapid prototyping processing and traditional processing

	Traditional processing	Rapid prototyping processing
material	Most metal, less metal plate and plastic	ABS, PMMA, wood, gypsum, etc
production cycle	2-4 months, sometimes even six months	only 2 to 7 days from the CAD model to the entity
Processing cost	High cost, mass production cost will reduce accordingly	Processing cost has nothing to do with bulk
Parts shape	Not too complex	Can produce complex parts

Product design method using rapid prototyping technology has following advantages [4]:

1）Functional test and evaluation

Although the assembly problem can be solved in the design software and analysis software, such as ANSYS, but it still can't meet the function verification and design requirements. Therefore, it needs rapid prototyping manufacturing samples to do functional test.

2）Eliminate the problem before manufacture mould

Samples are made by rapid prototyping technology first, the errors can be found, avoiding unnecessary loss.

3) Shorten product design time

Design and manufacture can be synchronized. Designers can design and modify the design at the same time, so the design can be completed soon.

Application of rapid prototyping technology in product design

Mechanical parts design

Parts manufactured by rapid prototyping technology can be assembled with other parts, in this way assembly validation and function test were done, which can examine the rationality of the design. Liu W D [5] made clamp by rapid prototyping technology and assembly, the final result satisfies the requirement of enterprise.

Medical model and prosthetic design

Rapid prototyping is applied to the teeth planting technology, product model was completed in CAD software, then the product entity was obtained by rapid prototyping for functional verification [6,7].

The innovation design of product design based on ergonomics

Rapid prototyping technology was used to validate the rationality and comfortable degree of product. As shown in fig.2 is product innovation design process based on rapid prototyping technology. ZHANG T H[8] innovation design of the atomizer box considering the ergonomics about the human body characteristics. With the rapid prototype samples, the design cycle was shortened, and the speed of spray products innovation design was accelerated.

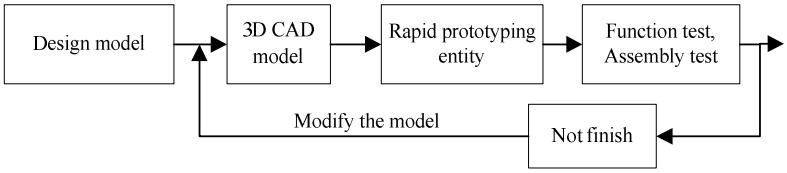

Fig.2 Product innovation design process based on rapid prototyping technology

The design of industrial design model

At present in China, industrial design model making teaching mainly is based on manual models, there are some limitations, such as the production cycle is long, it is difficult to achieve the complex appearance, etc[9].Using rapid prototyping technology can fast and truly show three-dimensional shape of model , shortening the cycle of model making, reflect the feasibility of the design idea , find problems as early as possible. A wheel model based on RP technology is shown in fig.3.

Fig.3 A wheel model based on RP technology

Fig.4 Cellular ceramics produced by rapid prototyping

Ceramic products design

Xu L Q [10] scanned purple clay teapots by using laser scanning technology. and handled data by using Geomagic software. Entity was manufactured by 3D printing technology and the design was optimized, Alberto Ortona[11] use selective laser curing to product honeycomb structure ceramic, he applied the method of 3D design combined with rapid prototyping technology, overcoming the limit of surface finish. Cellular ceramics produced by rapid prototyping is shown in fig.4.

Automobile modeling design

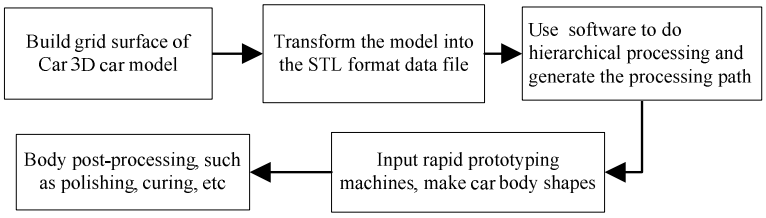

Fig.5 Rapid prototyping process of model car

For car body design process, the design method based on rapid prototyping technology can become a fast design method is suitable for China's national conditions. For the design of the automobile modeling, physical model is indispensable, because any car modeling approver could not only according to the pictures and the screen to examine and approval of modeling, They must see 1:1 entity model, domestic use the clay model, but the clay model is expensive. Rapid prototyping process of model car is shown in fig.5.

Conclusions

Rapid prototyping technology provides designers with intuitive, reliable reference model, ensuring the rationality of the design. Design method based on rapid prototyping technology will be a new design method, and it has obvious advantages and provids new ideas and new method for the product development and optimization.

Keywords: Electronic warfare command and control system, Complex electromagnetic environment, Effectiveness evaluation, AHP

Abstract. The effectiveness evaluation problem of electronic warfare command and control system (EWCCS) under complex electromagnetic environment is investigated by using the analytic hierarchy process (AHP) method. First, the evaluation hierarchy structures of EWCCS under complex electromagnetic environment are put forward and can be classified into target hierarchy, rule hierarchy and scheme hierarchy. Then, the AHP Algorithm is given as a preliminary knowledge to evaluate the effectiveness evaluation of EWCCS under complex electromagnetic environment. Finally, an effectiveness evaluation example of EWCCS under complex electromagnetic environment is considered by using AHP Algorithm.

Introduction

The electronic warfare equipments are important in modern information battles. With the development of the computer technology, the electronic warfare equipments become more and more complex, pregnable and damageable such that it is difficult to evaluate the performance and effectiveness of the electronic warfare equipments. Fuzzy-AHP in evaluation of ECM command effectiveness is investigated to calculate the influence degree of each ingredient and evaluate the ECM command effectiveness in [1]. According to its characteristics of insufficient information and uncertainty, the EW system operation effectiveness is evaluated by using the method of grey hierarchy evaluation in [2]. The effectiveness of instructed EW system is calculated by using analytic hierarchy process, the weighted coefficient of each guideline is defined, and the effectiveness of instructed EW system is calculated in [3]. An effectiveness evaluation index system of airborne ECM system is built, which can reflect the airborne ECM system capacity generally and impersonally in [4]. With the adoption of the grey system theory and the analytic hierarchy process (AHP), the evaluation model of the reconnaissance capabilities of the ECM reconnaissance troops based on the multilevel grey theory is created in [5].

Evaluation Hierarchy Structures of EWCCS Under Complex Electromagnetic Environment

According to the features of EWCCS under complex electromagnetic environment, many factors which are related with the performances of EWCCS under complex electromagnetic environment can be found out and can be classified into target hierarchy, rule hierarchy and scheme hierarchy.

The target hierarchy or the first hierarchy for effectiveness evaluation of EWCCS under complex electromagnetic environment can be denoted by A. The rule hierarchy of EWCCS under complex electromagnetic environment includes scouting and detecting ability B1, command and control ability B2, communicating and safeguarding ability B3, and battlefield electromagnetism environment B4. The hierarchy structure between the target hierarchy and the rule hierarchy can be shown in Figure 1.

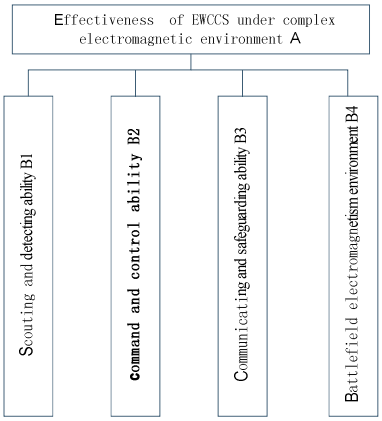

Fig. 1 The hierarchy structure between the target hierarchy and the rule hierarchy

The secondary hierarchy or rule hierarchy of B1 includes scouting and detecting method C11, scouting and detecting range C12, target density C13, probability of detecting target C14, alerting probability of C15, false-alarm probability of C16 and ability of identifying target C17. The hierarchy structure between the target hierarchy B1 and its scheme hierarchy can be shown in Figure 2.

The scheme hierarchy of B2 include ability of auxiliary decision C21, decision delay C22, ability of scientific decision C23, ability of threat judgment C24, campaign range C25, command scale C26, commanders' capability C27, and ability of weapon control C28. The hierarchy structure between the target hierarchy B2 and its scheme hierarchy can be shown in Figure 3.

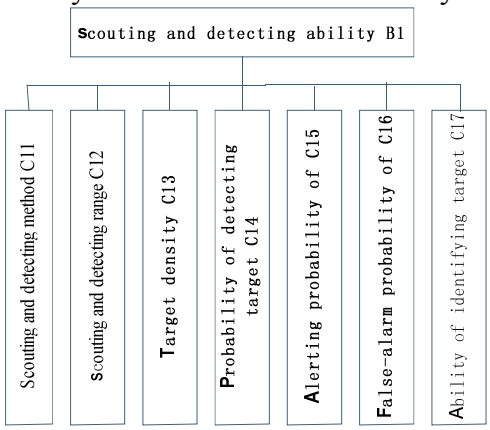

Fig. 2 The target hierarchy structure of B1

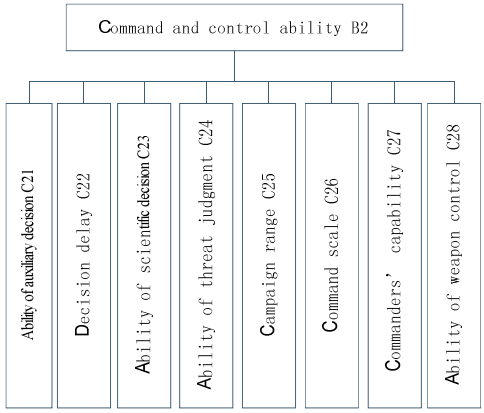

Fig. 3 The target hierarchy structure of B2

The scheme hierarchy of B3 include covering range C31, communicating capacity C32, operation types C33, miscode rate C34, communicating delay time C35, secrecy ability C36 and interlinkage ability C37. The hierarchy structure between the target hierarchy B3 and its scheme hierarchy can be shown in Figure 4.

The hierarchy structure of B4 includes quality of electromagnetism radiant point C41,density of electromagnetism signal C42,intensity of geomagnetism signal C43,parameters of geomagnetism signal C44. The hierarchy structure between the target hierarchy B4 and its scheme hierarchy can be shown in Figure 5.

A Numerical Example for Effectiveness Evaluation of EWCCS under Complex Electromagnetic Environment

Based on the AHP method, many generalized AHP methods and their applications are studied in [6, 7]. Assume that the experts give the relative importance of the criteria in the pair-wise judgment matrices of the EWS under complex electromagnetic environment. The corresponding pair-wise judgment matrix among complex electromagnetic environment include B1, B2, B3 and B4 can be given by the following table 1.

Table 1. The pair-wise judgment matrix among B1, B2, B3 and B4

A	B1	B2	B3	B4	W
B1	1	5	3	7	0.553
B2	0.2	1	0.3333	5	0.1313
B3	0.3333	3	1	6	0.2704
B4	0.1429	0.2	0.1667	1	0.0454
$\lambda_{max} = 4.2359$		$C.I. = 0.0786$		$C.R. = 0.0883 < 0.1$	

The corresponding pair-wise judgment matrix between C11, C12, C13, C14, C15, C16 and C17 in scouting and detecting ability B1 can be given by Table 2.

Table 2. The pair-wise judgment matrix among C11, C12, …, and C17

B1	C11	C12	C13	C14	C15	C16	C17	W
C11	1	0.5	0.5	1	6	3	4	0.1601
C12	2	1	1	2	9	4	3	0.252
C13	2	1	1	3	9	6	7	0.3194
C14	1	0.5	0.3333	1	5	2	2	0.1258
C15	0.1667	0.1111	0.1111	0.2	1	0.5	3	0.0369
C16	0.3333	0.25	0.1667	0.5	2	1	4	0.0701
C17	0.25	0.3333	0.1429	0.5	0.3333	0.25	1	0.0357
$\lambda_{max} = 7.5238$			$C.I. = 0.0873$			$C.R. = 0.0642 < 0.1$		

The corresponding pair-wise judgment matrix between C21, C22, C23, C24, C25, C26, C27, and C28 in command and control ability B2 can be given by can be given by Table3.

Table 3. The pair-wise judgment matrix among C21, C22, …, and C28

B2	C21	C22	C23	C24	C25	C26	C27	C28	W
C21	1	0.3333	1	3	1	4	4	4	0.1596
C22	3	1	3	5	3	6	6	6	0.343
C23	1	0.3333	1	3	1	4	4	4	0.1596
C24	0.3333	0.2	0.3333	1	0.3333	2	2	2	0.0666
C25	1	0.3333	1	3	1	4	2	3	0.1412
C26	0.25	0.1667	0.25	0.5	0.25	1	1	5	0.0506

$\lambda_{max} = 8.654$			$C.I. = 0.0934$				$C.R. = 0.0663 < 0.1$		

The corresponding pair-wise judgment matrix between C31, C32, C33, C34, C35, C36 and C37 in communicating and safeguarding ability B3 can be given by Table 4.

Table 4. The pair-wise judgment matrix among C31, C32, …, and C37

B3	C31	C32	C33	C34	C35	C36	C37	W
C31	1	2	3	4	7	5	2	0.326
C32	0.5	1	3	2	5	7	4	0.2674
C33	0.3333	0.3333	1	0.5	1	3	2	0.0964
C34	0.25	0.5	2	1	1	3	2	0.1196
C35	0.1429	0.2	1	1	1	2	3	0.0877
C36	0.2	0.1429	0.3333	0.3333	0.5	1	2	0.0496
C37	0.5	0.25	0.5	0.5	0.3333	0.5	1	0.0532
$\lambda_{max} = 7.6113$			$C.I. = 0.1019$			$C.R. = 0.0749 < 0.1$		

The corresponding pair-wise judgment matrix between C41, C42,C43 and C44 in battlefield electromagnetism environment B4 can be given by Table 5.

Table 5. The pair-wise judgment matrix among C41, C42, C43 and C44

B4	C41	C42	C43	C44	W
C41	1	1	6	2	0.3769
C42	1	1	3	5	0.3985
C43	0.1667	0.3333	1	0.3333	0.0747
C44	0.5	0.2	3	1	0.1449
$\lambda_{max} = 4.2507$		$C.I. = 0.0833$		$C.R. = 0.0939 < 0.1$	

From Table 1, we can know that the weight vector of B1, B2, B3 and B4 $[0.553 \quad 0.1313 \quad 0.2704 \quad 0.0454]^T$ can be shown by Figure 1. From Figure 1, we can directly find that the sort order of the relative importance among B1, B2, B3 and B4 is "B1»B3»B2»B4", where "»" implies that the former is more important than the later. We can obtain the weight vector of the components in the scheme hierarchy as

$$W = [0.0885 \quad 0.1394 \quad 0.1766 \quad 0.0696 \quad 0.0204 \quad 0.0388 \quad 0.0198 \quad 0.0209 \quad 0.045 \quad 0.209$$
$$0.0087 \quad 0.0185 \quad 0.0066 \quad 0.0052 \quad 0.0053 \quad 0.0881 \quad 0.0723 \quad 0.0261 \quad 0.0323 \quad 0.0237$$
$$0.0134 \quad 0.0144 \quad 0.0251 \quad 0.006 \quad 0.0123 \quad 0.0021 \quad]^T$$

which is shown in Figure 7. From Figure 7, we can directly know that the sort order of the relative importance among the components in the scheme hierarchy as "C13»C12»C11»C31»C32»C14 »C22»C16»C34»C33»C41»C35»C23=C21»C15»C17»C25»C37»C36»C43»C24»C26»C42»C28»C2 7»C44".

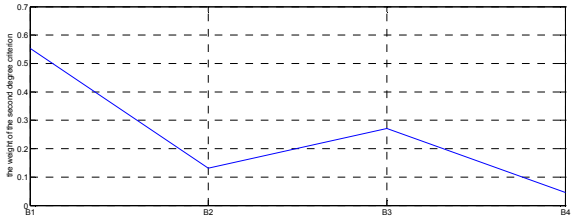

Fig. 6 Relative importance of the rule hierarchy

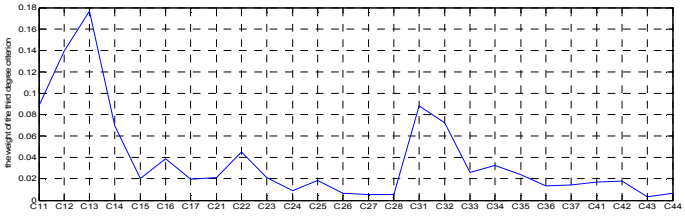

Fig. 7 Relative importance of the scheme hierarchy

Assume that the satisfactory degrees of components C13, C12, C11, C31, C32, C14, C22, C16, C34, C33, C41, C35, C23, C21, C15, C17, C25, C37, C36, C43, C24, C26, C42, C28, C27 and C44 in the scheme hierarchy are

$$R = [8 \quad 9 \quad 6 \quad 5 \quad 6 \quad 7 \quad 8 \quad 5 \quad 4 \quad 7 \quad 8 \quad 8 \quad 5 \quad 5 \quad 6 \quad 7 \quad 6 \quad 5 \quad 7 \quad 6 \quad 9 \quad 6 \quad 7 \quad 8 \quad 5 \quad 8 \quad]^T$$

Based on the above data, the effectiveness of EWCCS under complex electromagnetic environment is obtained as $U = 6.7201$ .Thus the effectiveness of the EWCCS under complex electromagnetic environment is satisfactory and distinct.

Conclusions

By using the AHP method, an effectiveness evaluation example of EWCCS under complex electromagnetic environment is considered, and the relative importance among the components in the scheme hierarchy of EWCCS under complex electromagnetic environment is proposed. In the next research, we will investigate the grey AHP method and the fuzzy AHP method to evaluate the effectiveness evaluation problem of EWCCS under complex electromagnetic environment.

Keywords: quadrotor; DSP; inertial measurement unit (IMU); optical flow sensor; attitude control;

Abstract. A problem of quadrotor's control system based on DSP is investigated in this paper. STMS320F28335 is used as the main processer, due to its advantages of high-speed processing capability and powerful floating point processing capability. The inertial measurement unit is selected for inner-loop attitude control, while the optical flow sensor is adopted for outer-loop attitude compensation. Infrared range finder is choosed for altitude control with PID method. Quadrotor uses XBee-Pro wireless module to contact with ground station and sends statement information in accordance with the Mavlink protocol. Test results show that the control system is reliable and can meet the requirement of the attitude control system.

Introduction

Unmanned air vehicles (UAVs) are self-propelled aerial robots. They can be equipped with various instruments and payloads, making them capable of performing various civilian or military tasks. Quadrotors are Vertical Take-Off and Landing (VTOL) four rotor helicopters with small size, light weight. Due to these characteristics, the quadrotor can operate in numerous robotic applications, for instance, search& rescue, inspection and exploration. Many scholars studied on it, proposed PID, LQR and other control algorithms according to its mathematical model, and made experimental verification in [1,2] . Cortex-M4 is adopted as the main processer and GPS is used to realize outdoor position control in [3]. A hardware system of quadrotor based on an embedded system of DSP/FPGA is designed in [4].

Texas Instruments (TI)'s DSP uses a modified Harvard architecture. It has strong data processing capabilities, rich peripherals, low power consumption, small size and cheaper than the processor which has the same performance.

Design of quadrotor's control system hardware

TMS320F28335 has 150MHz high-speed processing capability, 32-bit floating point processing unit, six DMA channels which support ADC, McBSP and EMIF, up to 18-way PWM output which has 6 unique way of higher precision PWM output, and 12-bit 16-channel ADC. Thanks to its floating-point unit, the user can quickly write control algorithms without spending too much time and effort in dealing with the fractional operation. The main processor is responsible for collecting attitude information from MTI-G high accuracy IMU, translational velocity from PX4FLOW []optical flow sensor and altitude from SHARP GP2Y0A02YK0F infrared range finder, and figuring out PWM to drive the 4 brushless motors according to the control algorithms. The control system hardware construction shows as Fig.1.

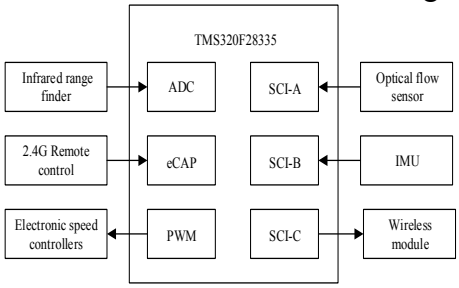

Fig. 1 Control system hardware construction

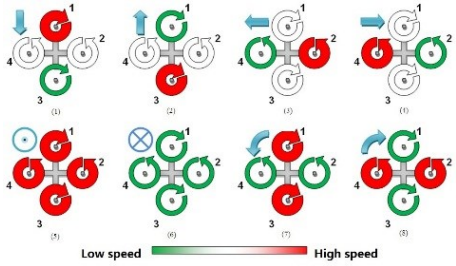

Fig. 2 Description of quadrotor motion

Attitude control's dynamic model

Quadrotor is controlled simply by changing the rotation speed of the four rotors (Fig. 2). The front and rear rotors (2, 4) rotate in a clockwise direction while the left and right rotors (1, 3) rotate in a counter-clockwise direction to balance the torque created by the spinning rotors. The up/down motion is achieved by increasing/decreasing the rotors speed while maintaining an equal individual speed. The forward/backward, left/right motions are achieved through a differential control strategy of rotors speed.

The control system can divide into attitude control and altitude control. According to attitude control's dynamic model, its state equation can be drawn as equation (1):

$$f(X,U)=\begin{pmatrix} x_2 \\ x_4x_6a_1+b_1U_2 \\ x_4 \\ x_2x_6a_2+b_2U_3 \\ x_6 \\ x_4x_2a_3+b_3U_4 \end{pmatrix} \tag{1}$$

$x_\alpha=[\varphi\ \dot{\varphi}\ \theta\ \dot{\theta}\ \psi\ \dot{\psi}]$ is state variable, $U=[U_1\ U_2\ U_3\ U_4]^T$ is input vector as equation (2). Equation (1) can be divided into pitch channel, roll channel and yaw channel from up to down.

$$\begin{cases} U_1=b(\Omega_1^2+\Omega_2^2+\Omega_3^2+\Omega_4^2) \\ U_2=b(-\Omega_2^2+\Omega_4^2) \\ U_3=b(\Omega_1^2-\Omega_3^2) \\ U_4=d(-\Omega_1^2+\Omega_2^2-\Omega_3^2+\Omega_4^2) \end{cases} \tag{2}$$

where Ω_α^2 is motor speed.

Design of hovering control algorithm

Attitude estimation based on the Inertial Measurement Unit usually makes certain errors, besides, GPS has disadvantages in low accuracy and environment limitation, so the quadrotor drifts a lot while hovering. A method based on optical flow sensor for hovering calibration is provided. The optical flow sensor is mounted in the bottom of the quadrotor aircraft. Attitude estimation is compensated to correct hovering with the horizontal velocity detected by the optical flow information. A cascaded (inner-outer loop) structure is often adopted. Fig. 3 is controller structure for hovering control of the quadrotor with the controller parameters roughly tuned in the experiments.

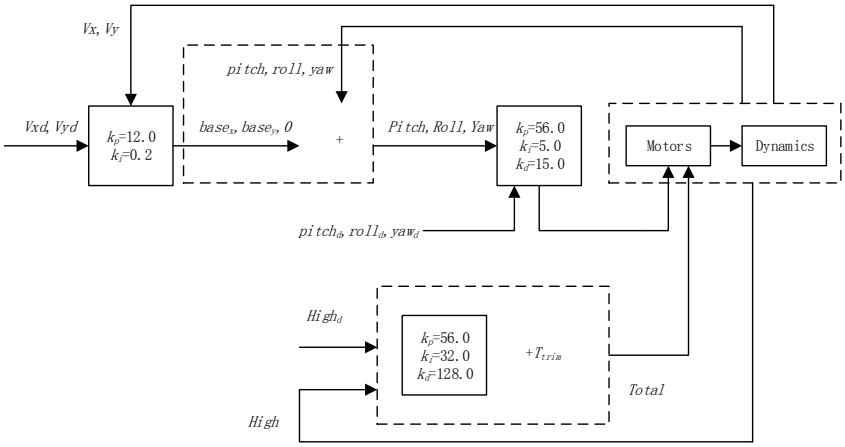

Fig. 3. Controller structure for hovering control

v_x and v_y are horizontal velocity in x-direction and y-direction, respectively, measured by optical flow sensor. v_x is proportional to pitch error $base_x$ and v_y to roll error $base_y$, besides, $v_x, v_y \in (-1.0,1.0)m/s$. The expected horizontal velocity is $0m/s$. PI controller is chose as the

out loop controller. v_x and v_y are control input , $base_x$ and $base_y$ are control output, then the real attitude angular are

$$\begin{cases} Pitch = pitch + base_x \\ Roll = roll + base_y \\ Yaw = yaw + 0 \end{cases} \quad (3)$$

where $pitch$, $roll$ and yaw are measured by magnetometer。

Due to the expected attitude angular are all 0°, we take the calibrated Pitch, Roll and Yaw as control input and use PID controller as the inner loop controller. The control output can be drawn as

$$\begin{cases} u_x = kp_x \cdot Pitch + ki_x \cdot \sum_0^n Pitch + kd_x \cdot v_p \\ u_y = kp_y \cdot Roll + ki_y \cdot \sum_0^n Roll + kd_y \cdot v_R \\ u_z = kp_z \cdot Yaw + ki_z \cdot \sum_0^n Yaw + kd_z \cdot v_Y \end{cases} \quad (4)$$

where v_p , v_R and v_Y are the angular rate measured by MTI-G.

Altitude control also uses PID controller, the altitude control output is

$$u_h = kp_h \cdot High + ki_h \cdot \sum_0^n High + kd_h \cdot (High_n - High_{n-1}) \quad (5)$$

where $High$ is the altitude measured by infrared range finder. Then the four duty cycles are

$$\begin{cases} CMPA1 = 4000 + u_x - u_z + u_h \\ CMPA2 = 4000 + u_y + u_z + u_h \\ CMPA3 = 4000 - u_x - u_z + u_h \\ CMPA4 = 4000 - u_y + u_z + u_h \end{cases} \quad (6)$$

where 4000 is the trim value T_{trim} during hovering.

Hovering control test

Fig. 4 is the description of quadrotor's hovering track. We can conclude that quadrotor can hovering within a circular area with a radius of 12cm. From Fig. 4. Fig. 5 to Fig. 7 are pitch, roll and yaw control effect respectively. We can draw that attitude can be stable within $\pm 5°$ and quadrotor can hover stably. Fig. 8 is altitude curve. In the take-off stage, about 8cm overshoot happened when it reach the maximum altitude; altitude stables at 50cm or so, the maximum error is less than 10cm; from takeoff to landing, the altitude control had a good performance.

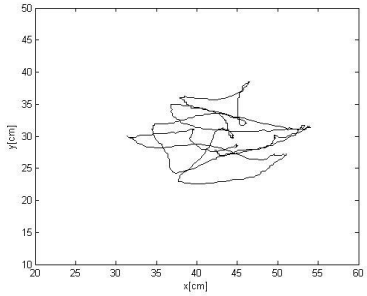

Fig.4. Description of quadrotor's hovering track

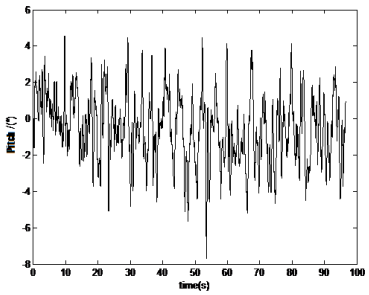

Fig.5. Pitch control curve

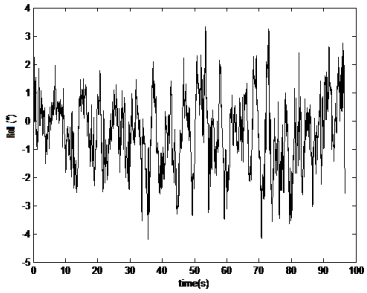

Fig.6. Roll control curve

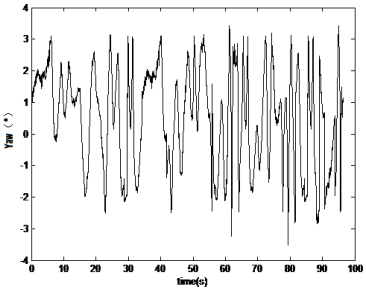

Fig.7. Yaw control curve

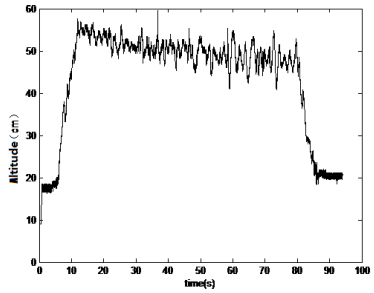

Fig.8.Altitude control curve

Conclusion

In this paper, we take advantage of STMS320F28335, and select MTI-G IMU, PX4FLOW optical flow sensor and SHARP GP2Y0A02YK0F infrared range finder to design quadrotors' control system. The hovering calibration idea with optical flow sensor is proven to be very effective in eliminating the long-term drift. Indoor experiments show that the control system has stable performance to meet the requirements of attitude control.

Keywords: minimum entropy deconvolution, morphological filtering, rolling bearing, fault diagnosis.

Abstract. One rolling bearing fault diagnosis method based on minimum entropy deconvolution (MED) and morphological filtering is proposed. Firstly, the strong background noise of rolling bearings is decreased by the MED method, then the morphological filtering which have different length of structure elements is designed and applied to the de-noised signal. Subsequently, bearing's fault characteristic frequency is extracted by the amplitude spectrum analysis to the best morphological filtering component which have the maximum kurtosis. This method is used to analyze both a simulated bearing signal and an experimental inner ring fault signal, and the good result validated the effectiveness of this method.

Introduction

The rolling bearing is an important and vulnerable part in rotating machinery, about 30% mechanical failure is caused by the local damage of the bearings. How to extract the weak impact features and repetition frequency from the strong background noise is the key to the fault diagnosis of rolling bearing. Morphological filter which bases on mathematical morphology transform is a nonlinear filtering method, Hu Aijun [1] used combined morphological filter to remove the random noise and impulse interference in vibration signal of rotating machinery for demodulation. Zhang Lijun [2] extracted the gearbox fault feature using mathematical morphological filtering. Because the difference morphological filtering demodulation involves only addition and subtraction, it avoids the window effect and mixing effect, so it can be used well in the field of fault diagnosis of rotating machinery. In this paper, the noise of fault rolling bearing vibration signal is decreased by the MED firstly, then the bearing's fault characteristic frequency is extracted by the difference morphological filter. In the morphological filtering and demodulation process, the difference morphological filter which has different length of structuring elements is designed and applied to analyze tentatively. At last, the best morphological filtering component is selected by the kurtosis criterion for the next demodulation.

MED principle

Local failure of rolling bearing can lead to periodic impact signal. Because of the influence of transfer path, the entropy becomes bigger after the convolution of the impact signal and transfer function. The core idea of MED is to remove the prominent sharp pulse process and to get the "certainty" in the signal through the deconvolution, and it usually uses maximum kurtosis value as the stop condition.

Actual collected rolling bearing fault vibration signal can be expressed as Eq. 1:

$$y(n) = h(n) * x(n) + s(n) \tag{1}$$

Here, $x(n)$ is the impact of the fault signal, $h(n)$is the transfer function, $s(n)$is the noise. To facilitate the analysis, $s(n)$ can be ignored firstly. The purpose of MED is to find a optimal deconvolution transfer function $w(n)$to calculate input signal $x(n)$ from the output signal $y(n)$ through Eq. 2.

$$x(n) = w(n) * y(n) \tag{2}$$

Assumed $\hat{w}(n)$ is the estimate value of $w(n)$, an estimated value $\hat{x}(n)$ of $x(n)$ would be obtained after deconvolution. The smaller the sequence entropy value is, the simpler the shape of $\hat{x}(n)$ is, and the stronger the impact of the signal is, also $\hat{w}(n)$ tends to optimal. Wiggins defined entropy function:

$$E[\hat{x}(n)] = [\sum_{n=1}^{N} \hat{x}^2(n)]^2 / \sum_{n=1}^{N} \hat{x}^4(n) \tag{3}$$

Therefore, MED essentially makes the recovered signal have the minimum entropy by constructing an "optimal" filter, Lee [3] seeks the optimal MED filter by the target function method. The detailed process can reference the reference [4].

Morphological Filtering

Principle of morphological filtering. Mathematical morphology has two kinds of basic form function: dilation and erosion. If *f(n)* is one-dimensional signal and its' domain is F={0,1,2,···,N-1}, *g(n)* is one-dimensional structure elements sequence and is defined in G={0,1,2,···,M-1}, and N≥M, then the dilation and erosion calculation is defined as:

$$(f \oplus g)(n) = \max[f(n-m) + g(m)], m \in G \tag{4}$$

$$(f \Theta g)(n) = \min[f(n+m) - g(m)], m \in G \tag{5}$$

Based on the dilation and erosion calculation, the open and close operation can be constructed respectively, the expression is:

$$(f \circ g)(n) = (f \Theta g \oplus g)(n) \tag{6}$$

$$(f \bullet g)(n) = (f \oplus g \Theta g)(n) \tag{7}$$

Mathematical morphology open operation can smooth the positive impact of the signal and the close operation can smooth the negative impact of the signal. For the purpose of demodulation, the positive and negative impact can be extracted by constructing a close-open margin calculation. The expressions is:

$$dif(f) = f \bullet g - f \circ g \tag{8}$$

The selection strategies of the structural elements based on kurtosis criterion. In the morphological filtering process, only the signal element which matches the structural element size and shape is reserved. So it is the decisive factor to select the shape, amplitude, and the length of the structural elements. Some structural elements are commonly used, such as flat, triangular, semicircular etc.. Although the more complex of the structure element shape is, and the stronger its filtering ability is, it consumes more calculating time. Reference [5] points out that the structure of element shape has little effect on the filtering effect, considering the signal characteristic and the calculation complexity, the flat structure element is selected in this paper. In order to determine the appropriate structure elements length, Nikolaou and Antoniadis [6] proposed that structure element length should be 0.6 times to the fault pulse period (T).It becomes the experience formula of choosing the length of structural elements. The paper set the length of structural elements to 0.1T, 0.2T, 0.3T···T separately, then analyzes the signal using difference filter to generate 10 morphological filtering components, and selects the maximum kurtosis component to analyze the fault spectrum.

Analysis of simulation signal

Literature [7] gives the rolling bearing fault model with inner race fault. It is:

$$\begin{cases} x(t) = s(t) + n(t) = \sum_i A_i h(t - iT - \tau_i) + n(t) \\ A_i = A_0 \cos(2\pi f_r t + \varphi_A) + C_A \\ h(t) = e^{-Bt} \cos(2\pi f_n t + \varphi_m) \end{cases} \tag{9}$$

Set the sample frequency f_s=20kHz, the rotation frequency f_r=20Hz, the natural frequency of the system f_n=3kHz, the inner fault characteristic frequency f_i=120Hz, the noise component is added and the SNR of $x(t)$ is -9dB, amping radio β=0.04.The time-domain waveform and envelope spectrum of simulated signal $x(t)$ is shown in Fig. 1 and Fig. 2.

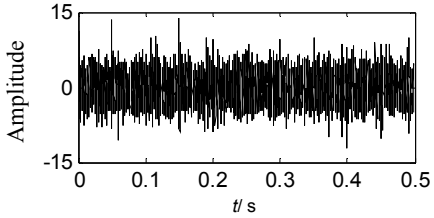

Fig. 1 Waveform of simulation signal

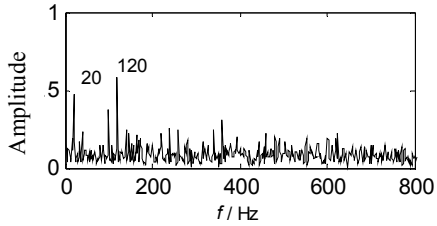

Fig. 2 Envelope spectrum of simulation signal

Because of the noise, the impact fault characteristic of waveform is not obvious in Fig.1. Although the peak is corresponding to the inner ring fault characteristic frequency in Fig.2, other frequency components of the fault are not easy to find. The result analyzed by MED is shown in Fig.3. We can see that the impact characteristic of the signal is obvious. Then the paper constructs the difference morphological filtering according to the construction method of the structure element, and gets the 10 morphological filtering components. The kurtosis values of each morphological filtering component are calculated in Table1. We can find that the L=T morphological filter component's kurtosis value is maximum. Fig.4 shows its amplitude spectrum. The peak is obvious at the inner race fault frequency and its multiplication frequency, and it is clear that the inner ring fault frequency and rotating frequency modulation characteristic.

0.1T	0.2T	0.3T	0.4T	0.5T	0.6T	0.7T	0.8T	0.9T	1T
1.139	1.287	1.380	1.664	1.665	2.162	2.192	3.175	3.819	6.240

Fault diagnosis example

The paper selects the data of American Case Western Reserve University bearing data center for the inner ring fault diagnosis. The bearing type is 6205-2RS JEM SKF in the experiment. The pitch circle diameter D=39.04mm, diameter of steel ball d=7.94mm, rolling number n=9, pressure angle α =0 °, rotating frequency f_r=28.7Hz. The inner ring fault characteristic frequency of bearing is :

$$f_i = \frac{n}{2}(1+\frac{d}{D}\cos\alpha) f_r = 155.4Hz \tag{8}$$

Fig.5 is the time domain waveform and Fig.6 is the amplitude spectrum of the inner ring fault signal. Fig.5 reflects the impact and the noise are obvious. There is a small peak at 155.3Hz in Fig.6, corresponding to the inner ring fault characteristic frequency of bearing, it showes that it may be the inner fault. The MED de-noise method is applied to the fault signal, and we regards the inner fault impact cycle as the standard cycle T of structure elements to morphology filtering. 10 morphological filtering components are generated. The kurtosis value of each component is shown in Table 2.

When the length of structural elements is L=0.1T, the kurtosis value of morphological filtering component is maximum, so the paper does the spectral analysis to this component, the result is shown in Fig.7. The frequency and frequency doubling of fault is in the graph, the order as high as 6. Fig.8 is

the inner ring fault signal's envelope spectrum, although there is inner fault frequency of bearing, but only 2 times frequency component is obvious. So the paper's method can more effectively in extracting the impact characteristic of rolling bearing fault and frequency doubling.

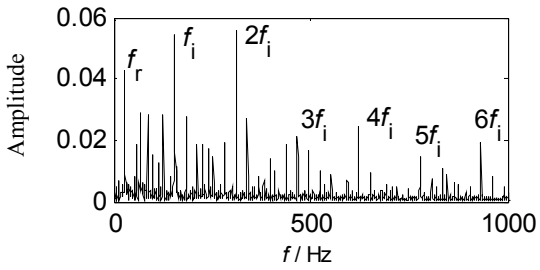

Fig.7 Analysis result of fault signal

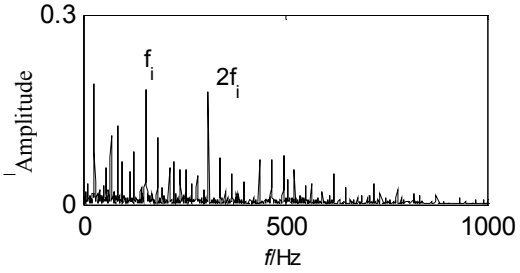

Fig.8 Envelope spectrum of fault signal

Conclusion

The paper proposes one rolling bearing fault diagnosis method based on MED and morphological filter. The MED has good ability of de-noise and difference morphological filtering can extract impact characteristic in the signal. The result of simulated signal and example signal showes that this method can extract the rolling bearing impact characteristic and frequency doubling effectively, and the result is better than traditional envelope spectrum.

Keywords: Disk Spring, Stress Relaxation, Failure, Life Time.

Abstract. Prediction of disk spring failure life due to stress relaxation is necessary for users; the problem was not solved before. According to special test requirement, we modified a 100N mechanical testing machine into high temperature testing equipment which can be used for different types of disk spring. With a test for 36 days on a group of 45×22.5×3.5×2.5 mm disk springs, a result of prediction of 3.38% load loss ratio after 12 years relaxation is obtained, these disk springs are qualified. Our modified equipment has the advantages of real time, heavy loading, high sensitivity and good generality.

Introduction

Disk spring has the characteristics of super high elasticity, compact axial size, variable stiffness etc, it is widely used in the area of mechanism of preloading, seal, mechanism reset, security protection etc. Disk spring acts as very important role; once it is installed, it is to be used for a long period up to 10 years [1].

Stress relaxation is a common phenomenon in metal material or element. The stress under constant strain would be decreased with the lapse of time. It is the main form of elastic element failure [2,3].

There was no disk spring stress relaxation testing method and equipment for a long time, and there was no special requirement for it in national standard GB/T1972-2005. However, with the production and use of high temperature disk spring, the higher the temperature, the greater the influence. It is eager to design and manufacture disk spring relaxation testing equipment [4].

Equipment requirements

Due to the characteristics of disk spring, the equipment should satisfy following requirements:

Real time ability. To predict the load loss ratio after some years, the stress relaxation curve is needed to extrapolate the life time. To obtain the stress relaxation curve, the real time load changes should be measured at high temperature.

Heavy loading. Disk spring can be used for heavy loading. 40×20.4×2.25×3.15 mm disk spring can be loaded on 6540N, 100×51×6×8.2 mm for 48000N and 200×102×8×13.6 mm for 76400N.

High sensitivity. Load change caused by stress relaxation of disk spring is very small for a short period of time, the sensitivity requirements for the test system is very high.

Generality. Standard disk spring is divided into 3 series, each series is divided in to 3 classes, each class has 29 types. Coupled with non standard disk spring, the specifications is very complex. Testing system should have good generality.

Heating device. For simulation of the actual environment at different temperature, testing equipment should have a thermal isolation furnace.

Test Principle

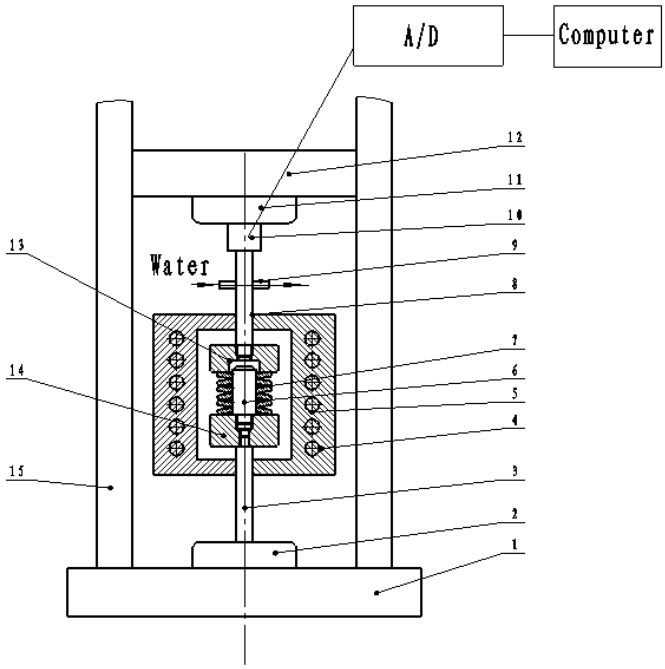
There are two methods for testing [5]:

Screw or bolt method. The disk spring string is put in a bolt and the amount of compression of each disk spring is calculated. We firstly made a mark on the bolt as initial hight of the string and measured the corresponding load, then locked the string by a nut until next measurement. We remeasured the load on the same mark after a certain time, then we obtained the stress relaxation curve.

The results could not be accurate, although this method is simple. This is because of huge elastic coefficient and small stress relaxtion of disk spring. Obviously, this method is not feasible.

Real time testing method. Prof. Su, De Sheng from Material Institute of Tianjin University, China, proposed a method for helical spring [6]. In this method, the spring is preloaded and the reduction of force is recorded by computer using A/D conversion. This method can reflect the real stress relaxation more accurately.

Equipment Modification



1-the base of electric universal mechanical testing machine 2-lower flange 3-lower support connecting link 4-electric furnace 5-electric heating wire 6-inner rod 7-disk spring 8-upper support connecting link 9-cooling water pipe 10-senser 11-upper flange 12-beam of electric universal mechanical testing machine 13-upper platen 14-lower platen 15- portal rigid frame of electric universal mechanical testing machine

Fig. 1 Diagram of real time testing equipment

Due to heavier load of disk spring and smaller deformation, the stress relaxation numerical value is extremely small. Required real time testing equipment should provide sufficient force and precise range of measurement. A 100N mechanical testing machine meets the requirements for the experiment, and the modification diagrammatic sketch is shown in Fig. 1. A Photo of the equipment is shown in Fig. 2.

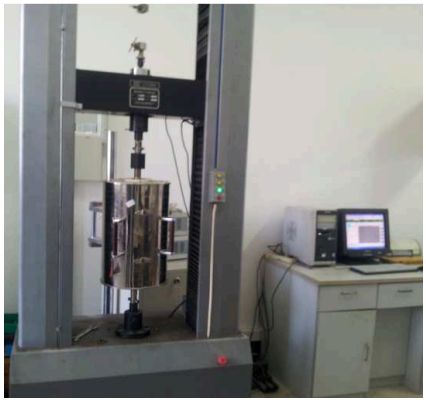


Fig. 2 Photograph of high temperature stress relaxation testing equipment

The support link is Lengthened, and the disk springs are placed in electric heating furnace. All the disk springs are put on inner rod. The force is transffered through upper and lower platen. The upper link rod is cooled by flowing water to prevent senser from being heated. Different disk spring can be measured by replacing inner rod, and the generality is achived easily.

Measurement Example

Disk spring, material: 60Si2MnA; specification: 45×22.5×3.5×2.5 mm; 40 disk springs are cascaded by pairs, each pair has 2 double disks face to face; rated load: 15.4 kN. Results measured at room temperature are shown in Table 1.

Table 1 Results of real time testing of stress relaxation of disk spring

Time [min]	Ln(time)	P [kN]
0		15.4
1	0	15.35
3	1.0986	15.3
5	1.6094	15.26
10	2.3025	15.23
30	3.4012	15.2
1020	6.9276	15.11
1200	7.09007	15.1
2640	7.8785	15.09
2690	7.8972	15.08
4070	8.3114	15.07
6510	8.7811	15.06
9390	9.1474	15.05
10830	9.29	15.05
13710	9.5259	15.05
19470	9.8766	15.02
32430	10.3868	15.01
36750	10.81189	15.01
45390	10.723	15
52590	10.8703	15

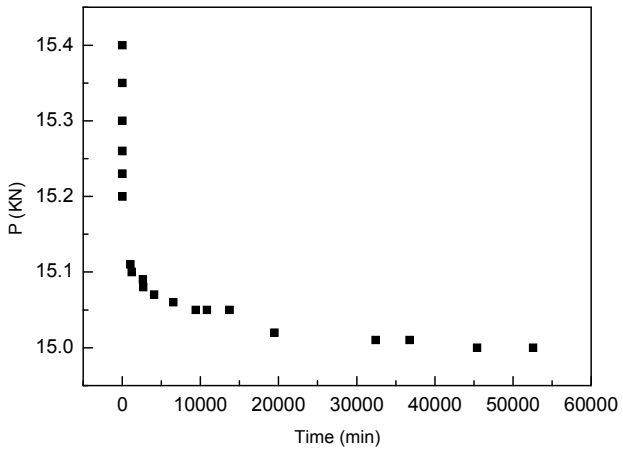

Fig. 3 Curve of load vs. time

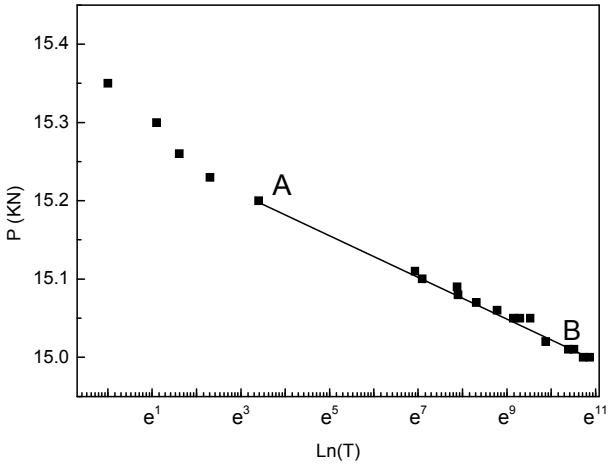

Fig. 4 Ln curve of load vs. time

Analysis

Fast and Slow Stages. In Fig. 3, it shows two stages of stress relaxation. One is fast stage (0~1000 min), another is slow stage (>1000 min).

Load loss ratio.

$$V = \frac{\Delta P}{P_0} \times 100\% = \frac{15.4 - 15}{15.4} \times 100\% = 2.60\% \quad (1)$$

Life time. The first stage is considered as permanent plastic deformation induced at the corner of disk spring, and the second stage is real stress relaxation. The relationship between load loss ratio and logarithm of time is linear. A linear equition is obtained from Fig. 4 [7]

$$y = a_0 - b \ln t \quad (2)$$

in which a_0 is initial load, b is the second stage line slope.

In the period from 1000 min to 60 days, a_0 =15.306 and b =0.028278 can be calculated from two selected points A (6.93, 15.11) and B (10.82, 15.00).

$$y = 15.306 - 0.028278 \ln t \quad (3)$$

The predicted life time of disk spring is 12 years. Use Eq. 3, load at that time can be calculated:

$$y = 15.306 - 0.028278 \ln t = 15.306 - 0.028278 \ln 12 \times 365 \times 12 \times 60 = 14.88 KN \quad (4)$$

Load loss ratio is

$$V = \frac{15.4 - 14.88}{15.4} \times 100\% = 3.38\% \quad (5)$$

Conclusion

Due to small stress relaxation and huge load of disk spring, the testing for stress relaxation is difficult to achieve. Using an electric mechanic testing machine modified with adding device, the testing measurement is successfully achieved. Not only the problem is solved, but also the precision and the reliability is ensured. The equipment development cost and time are greatly saved. By testing the stress relaxation, long time load loss ratio of disk spring can be calculated. By replacing mechanical fixture, disk spring with different specifications can be tested. The equipment has capability of high temperature testing with electric heating furnace.

Keywords: silt brick-making; brick cutting machine; automatic control

Abstract. Brick cutting machine is the important device during the process of making bricks. The automatic control system, device of power and the pattern of cutting machine have been developing well. The new ideas, new technology and achievement of the brick cutting machine are taken out. The important achievement and application of the cutting machines are introduced, as well as the development tendency.

Foreword

As the rapid development of national economy, urban and rural construction, brick industry advocates saving land resources and energy, protecting environment and utilizing resources adequately. Making bricks with slit[1] can effectively protect the land resources and solve the problem of rivers blocked.

Slit brick cutter, an important part of the brick making machine, mainly consists of cutting platform, steel wire, steel wire hook, power plant and automatic control system. Brick-cutting machine has developed rapidly, the power system has developed from electrical machine to the hydraulic system. In terms of control system, relay control has been instead of Programmable Logic Controller(PLC). A good design of cutting machine can improve the production efficiency and quality, and it can save much silt resource. Therefore the design of cutter is valued by brick-making researchers.

Theory of silt brick-making and cutter

The main raw materials of mud sintered porous bricks are silt, coal gangue and something used to make micropores, they are mixed at a certain proportion, stirred, extruded, cut to prepare for making silt-bricks.

Currently the advanced cutter has basically realized intelligence and automation. When the cutter detects the slugs put out, it begins to cut mud strips constantly with steel wire under the control of PLC. In order to keep cross section neat, the cutting plane and mud should be synchronously moved. When the cutting machine finish cutting slugs, the accelerate belt quickly sends briquets to the next workbench. The whole cutter device is equipped with alarm system, once the steel wire is broken or equipment stops running, the device will buzz to alarm.

Development of brick cutting machine

Cutter power system

At present many enterprises use linkage to cut slugs, the working process is that motor drives the clutch, then drives the connecting rod to make the wire rack cut the mud constantly. The connecting rod cutter has many disadvantages [2]: (1) The working noise is loud, which will cause vibration and working process is not smooth. (2)The structure is complex, there are always a lot of faults, and it is not easy to maintain and repair. (3)The automation degree is low, labor force consumption is too large. (4)It is difficult to calculate the part size in detail and process accurately.

The domestic researchers have developed the hydraulic cutter with low noise, small energy consumption and high productivity [3]. This kind of cutter adopts hydraulic system as the power to cut mud, the largest stroke is 260 mm - 800 mm, and the maximum working pressure is 25Mpa. Shenzhen WoPeng limited company [4] in 2011 applied hydraulic cutting technology to concrete nondestructive cutting, and successfully developed the hydraulic concrete wall sawing machine and hydraulic rope saw machine and any other products. These products can be applied to cut any kind of clay bar. Hydraulic cutter has more prominent advantages: (1) Low energy consumption, energy is used more reasonably. (2)Working noise is low, operation is smooth, and guidance precision is better. (3)Hydraulic push rod system is simple, it's more convenient to control the cutting system. (4)Hydraulic push rod system uses the technology of two-stage pressure regulation, when the working pressure is higher than the safety system, it will relieve pressure automatically to ensure the security of machine. The disadvantage is that once the tubing is aged, it will leak easily, it is hard to maintain and the cost is high.

Cutter control system

Nowadays some brick enterprises still use the traditional relay to control the cutter. Relay consists of the middle relay, counter, time relay and on-off contacts. It achieves the goal of automatic cutting through the logic combination of contacts. Although the cutter with relay control is easy to manufacture and the cost is low, the number of contacts is large[5], the wire is complex, equipment is easy to age, control accuracy is not high, a loosen contact will affect the entire cutting system control and it is more difficult to find faults. Therefore, authorities stated that relay control must convert to PLC soon.

There has been great development in the automatic control technology because of PLC, the production efficiency is also greatly increased. The working process of the cutter controlled by PLC is that when the mud is detected by signal detector, the belt begins to turn to carry the mud from the vacuum extruder extrusion into the cutting device, all the information is transmitted to the control center, then the motor rotates to drive the cutting plane and conveyor synchronously. At the same time, the slug will be cut by the steel wire into certain shape neatly.

Wei Xiaolin[6] has used PLC to control the cutter, the automation of whole process can be implemented, such as sending board, feeding, demolding and cutting bricks. All the actions in cutting process are controlled by PLC, the operation is stable and reliable. Compared with the traditional relay control, the cutter controlled by PLC is higher reliability, stronger anti-interference ability, wider range, and easily programmed. It's proved that the qualification rate of products have reached 98% above, the brick-making number is more than 1200 per hour and various performance indicators of cutter meet the national standard.

Cutting patterns

At present the models and types are various, the cutting quantity and quality also need higher requirements, so various models of cutter are required to cut all kinds of bricks. Cutting pattern can be designed according to product model, transverse section and cutting quantity. Some commonly used cutting systems are illustrated below.

Vertical cutting. Vertical cutting refers to that the cutting wire, strained horizontally, cuts the mud vertically when the mud is transferred below the steel frame. After cutting, the cutting wire returns to top from the bottom, happening to separate the cut bricks. The vertical cutter invented by Liu Yunwu can make the cutting section smooth, make the size accurate, and it can also control the length at random. Either the hard or soft slug can be cut.

Combined cutting. The sizes of some productions are irregular, if cutting just once, it can't meet the requirement. Then the machine should repeatedly cut in order to produce various shapes of brick-products.

Model 4142 General Cutter invented by German Keller Company, adopts the combination of vertical and horizontal integration cutting system [7]. Combined cutting makes the cutting action at the same time or in turns. For example: the vertical cutting + chamfer + transverse cutting.

Vibrating cutting. Many producers add some combustible materials such as waste paper, waste wood chips, packaging rubbish and straw to the adobe, and then sintering bricks can form tiny holes

in order to achieve the purpose of heat preservation and heat insulation. But these additives may cause the cutting cross section deformation during cutting process, also can jam the inner hole of adobe, and the dry air cannot bring out the water vapor.

Making the steel wire reverberate under the action of magnet to prevent or reduce the occurrence of this situation, which is called vibration cutting[8].A good vibration cutting can increase the rate of hole, and the cutting deformation is reduced to minimum. The wire needs highly elastic so that the wire will avoid broken under the influence of resonance frequency.

Vista

The development trend of cutter is intelligent and systematic. The researchers of cutter pay more attention to the reliability, security, economy and environment. At present although domestic tile production equipments have developed quickly and the brick-making technology has made great progress, there is still a large gap compared with abroad in many ways. It is necessary to improve the structure property, research technology, productions quality and efficiency to meet the requirements of the brick market.

(1) Steel wire fracture is almost inevitable because of the alternate bending and tension. When the steel wire is cutting the slush mud, the resistance and friction loss will cause the wire fatigue and fracture. The quality of wire is critical to the production efficiency, so how to improve the quality of steel wire is still the researching focus in the future.

(2) The cross section of brick is not neat or cutting incompletely because of the impurity in sludge. In the future the mud material must be mixed fully before cutting, making sure the impurities particle size is less than 3 mm. In the aspect of cutting system, vibration cutting can be used to improve the cutting quality.

(3) Currently many brick enterprises equipments are relatively backward in the country. The researching focus is how the vacuum brick-making machine extrude more slugs than before. There are various bricks on the market, if each kind of brick only can be produced by one special cutter, it will obviously waste time. In the future, the procedure of each kind of production will be programmed into the cutter control system, when producing one kind of brick, the related program will be called. The cutting efficiency is greatly improved.

Peroration

Cutting machines play an important role in the brick industry, the development of cutters directly affect the production quality and efficiency. At present, the cutter structure is complete increasingly, production efficiency and degree of automation are very high. The rapid development of the national economy and housing industry modernization create a wide market for block production equipments. Strengthening technology innovation, developing advanced, practical and reliable products are the top priority. The development of the cutter for bricks has brought positive impact on the brick industry.

The design of the single-phase inverter based on DSP (TMS320F2812)

Zhaoxia Zhou[1,a], Jiaen Huang[2,b]

[1.2]School of Information Science & Technology, Xiamen University Tan Kah Kee College

[a]xia1108@126.com, [b]531462635@qq.com

Keywords: DC-DC, DC-AC, Single-phase, full-bridge inverter, SPWM, DSP

Abstract. This paper designs a single-phase inverter.Battery as a 12V DC input, and output for the 24V,50 HZ standard AC wave. The load is resistive.The power supply adopts the Boost booster and two full-bridge inverter transform. For the control circuit, the preceding Boost converter using tl494 chip control closed-loop feedback and for the inverter part, adopting the 6N137 to finish the optical coupling isolation.Then,through the DSP (TMS320F2812) to complete the output of SPWM modulation.And the modulated SPWM signal can drive chip IR211 conducting the full bridge inverter. Finally, through a low-pass filter output the standard sine AC inverter power.

Introduction

In the electronic technology,Inverter technology is the most major and cored one. it combines modern power transformation, the analog and digital electronic technology, PWM technology, frequency meter, phase modulation technology, switching power supply technology and control technology, etc.At present, the digital AC power has gained rapid development, and the DSP is widely applied to the power supply .For using DSP chip as the core control chip, the SPWM wave signal produced by DSP can help the inverter power supply offer more perfect sine wave to its continuity [1], and it can be got low noise and high efficiency advantage through using of DSP.

Design index and design scheme

Design index: Design a single-phase inverter power supply.The input voltage is 12 V DC.The output RMS voltage is 24 V AC sinusoidal alternating current.The load is resistive.Specific indicators :

① the rated input voltage: $U_i = 12V$
output voltage: $U_{ORMS} = 24 \pm 0.5V$,frequency: f_O=50±0.5Hz

②Full rated output power:11.52W（$R_L = 100\Omega$）;Output sine wave voltage, $THD \le 3\%$

③Tunable output frequency:40HZ~60HZ

Structure diagram is shown in figure 1:

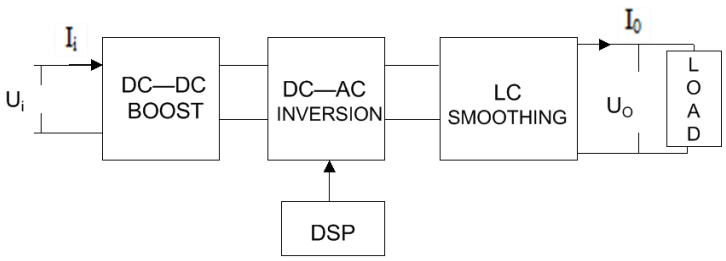

Figure 1:The hardware design block diagram

The overall design scheme: System has two power supply, the input of the 12 v DC voltage supply the DC - DC converter and the DC-AC converter,and these two converters respectively drive the chip TL494 and chip IR2111 work normally. By 7805 chip, the input voltage DC 12 v can be changed to an output with 5 v linear regulated power supply.It can drive 6N137, 74LS06, DSP(TMS320F2812) work normally.

System design block diagram is shown in figure 2

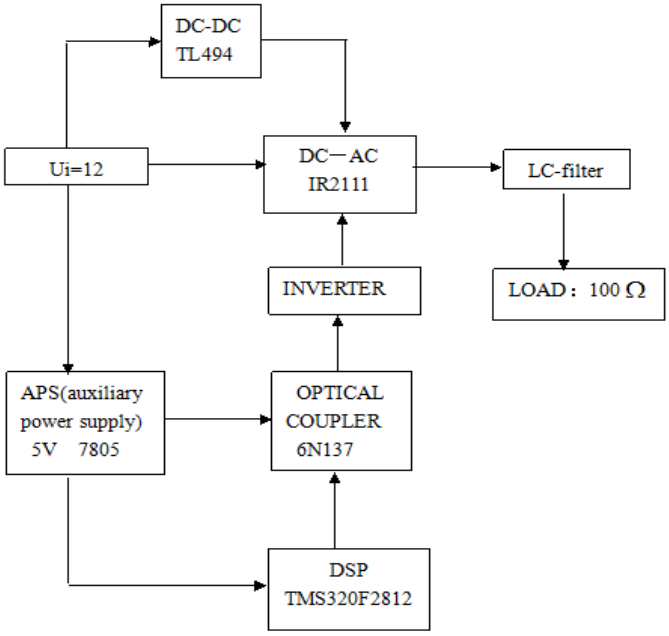

Figure 2 System design diagram

The design principle of each module

Boost DC - DC boosted circuit: Boost DC - DC converter.when the MOS tube opened , inductance L will store energy by V_{in} ,making the current increasing [2]. At the same time, the corresponding polarity of the electromotive force will change.Left is positive, negative right.The load's power supply provided by the capacitance C.When the MOS tube is cut-off,the current which through the inductive L will decrease constantly.And,the corresponding polarity of the electromotive force will change again.At this moment, the polarity is the same as V_{in} .After voltage's superposition and a part of power consumption on the diode, all the rest voltage was applied to the load.Meanwhile,the capacitor is recharged.So the DC voltage finishes the transformation from low to high.The principle diagram is shown in figure 3:

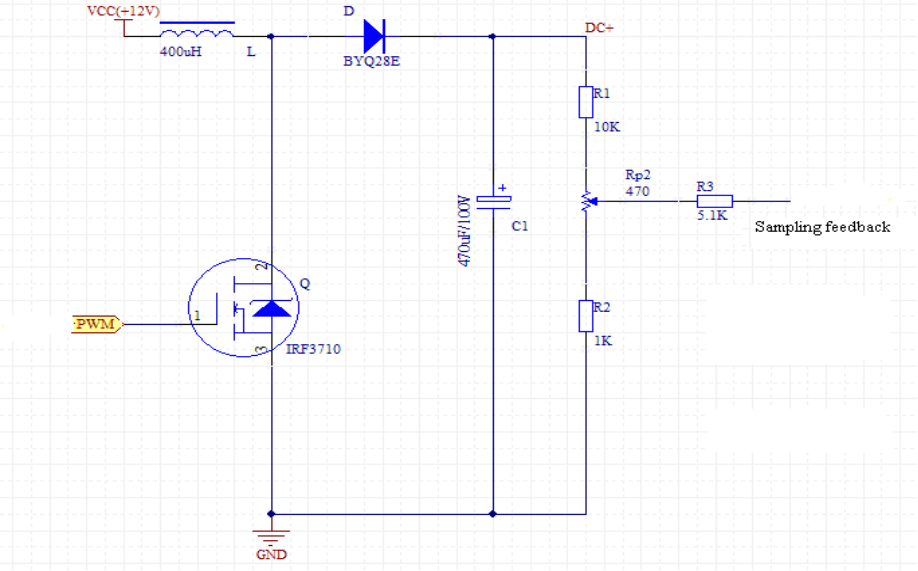

Figure 3 The principle diagram of the DC - DC boost converter

DC - DC transform drive circuit: DC - DC converter drive circuit composed of TL494 PWM pulse[3]. Modulate PWM pulse's frequency to 50KHZ ,choosing oscillation capacitance CT of 1000 PFand the resistance RT is 22 k Ω . The working principle diagram as shown in figure 4:

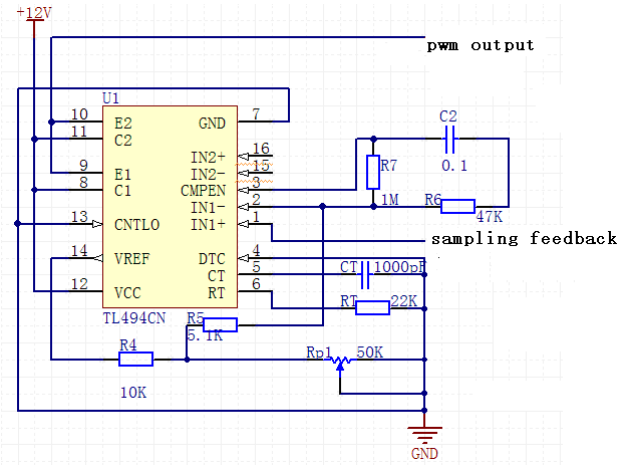

Figure 4 The principle diagram of the DC - DC converter controller

DC-ACinverter circuit: DC/AC adopts single-phase full bridge inverter circuit [4].It is made up of four IRF3710 bridge inverter circuit.In order to power the load, it uses the half bridge driver IR2111 which provide the drive signal to change the DC into 50 HZ AC .The working principle diagram as shown in figure 5:

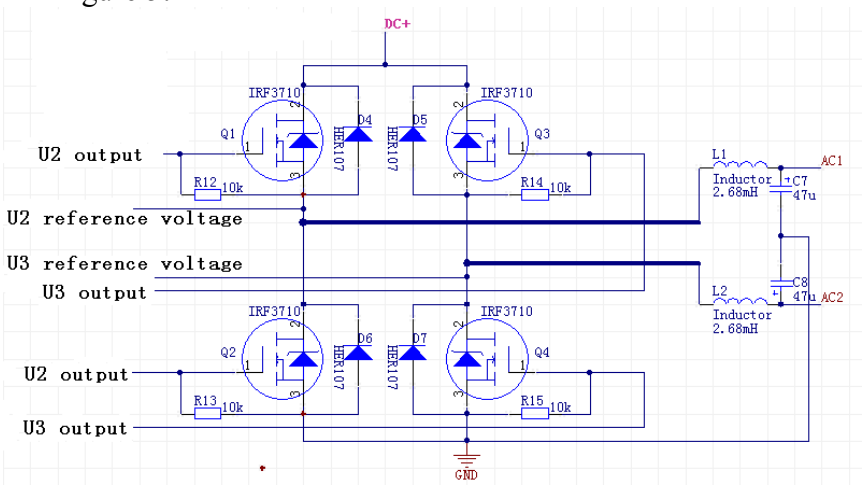

Figure 5 The principle diagram of the DC - AC inverter circuit

DC - AC converter drive circuit: The design of DC-AC inverter circuit adopts IR2111 half bridge driver chip.Single polarity SPWM signal generated by the DSP goes through the optical coupling isolation and the inverting step-up by74 LS06 inverter,the single output as an input conveies to the IR2111 half bridge driver chip.As long as controlling these two pieces of IR2111 half bridge driver chip can complete the drive of single phase full bridge inverter circuit.The working principle diagram is shown in figure 6:

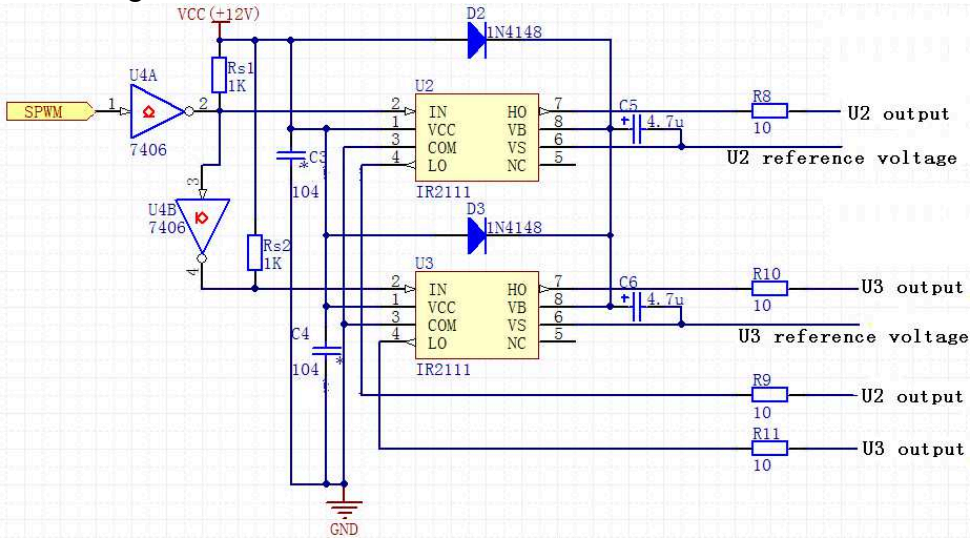

Figure 6 The principle diagram of the DC - AC converter drive circuit

System joint debugging

When in the test, debugging the situation without load first,the author adjust RP2 to make the output sampling voltage of DC - DC converter become 2.4 V.At this point, through the voltmeter measurement,we can see the DC - DC converter's output voltage is 34 v.Then the author adjusts the SPWM signal's modulation degree to1 as the input, and the output true RMS voltage of whole hardware and software system reachs 24 v. After finishing the no load debugging, the author disconnects the input power.In the output side,the author puts a 1 100 Ω resistance (load), making the whole system into a state of on-load.Opening the power supply,the Author adjusts RP2 again to make output sampling voltage of DC - DC converter become 2.4 V.Then,the author adjust the Rp1, to make the internal reference voltage of TL494 reach 2.4 V.Eventually, make DC - DC converter's output voltage reach 34 V.Meanwhile, the author adjust the SPWM signal modulation degree to 1, making the output true RMS voltage of whole hardware and software system reach 24V, and the output current is 0.25A.At this time, the whole hardware and software system debugging has completed.Physical test waveform which is the result of running on-load as shown in figure 9:

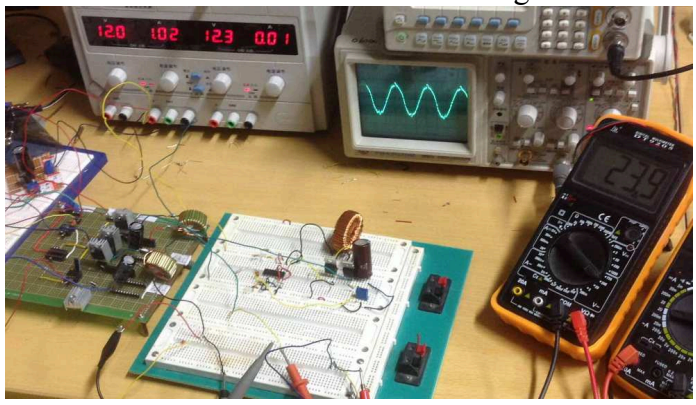

Figure 9 Waveform figure with on-load

Conclusion

Based on TMS320F2812 DSP chip can realize the drive digital control for inverter power supply. In the process of control, it should be point out that the reliability of hardware and software system is high, the precision affected by environment is weak, and it has strong programming. So it is superior to the traditional analog circuit. The result of experimental test obtained good sine waveform.

Keywords: LDO, power supply rejection ratio, ultra-low output buffer, compensation, error amplifier

Abstract. This study develops a low dropout regulator linear regulator, characterized by a high power supply rejection ratio using ultra-low output resistance buffer and two-stage error amplifiers. The high power supply rejection is based on a closed-loop LDO regulator. The ultra-low output resistance buffer achieves ultra-low output impedance with dual shunt feedback loops, subsequently improving load and line regulations, as well as the transient response for low voltage applications. The proposed LDO regulator linear regulator functions under an input voltage of 1.8~3V, and the output voltage can be maintained at around 1.27V. Moreover, its output voltage is independent of input voltage. The proposed regulator is applicable to light-emitting diode driver integrated circuits. The layout chip area of the LDO linear regulator is 21.5μm × 42.6μm.

Introduction

With the widespread use of battery-powered portable devices such as mobile phones, laptops, and various handheld devices, power management should be one of priority concern when attempting to maximize the battery lifetime and provide energy to multiple on-chip blocks. In LDO regulator design, a linear LDO regulator is characterized by its ability to remain stable under various operating situations. This regulator can also provide regulated low-noise and precision supply voltage. Capable of providing a precise output voltage and regulating the output noise, the linear LDO regulator is increasingly applied. In linear LDO regulator design, stability in various operating conditions should be of priority concern. Many frequency compensation schemes have been developed to ensure the stability of the regulator. The conventional approach forms the left half plane zero frequency by using the equivalent series resistance of the output capacitor. However, this approach is limited by its insufficient transient responses, owing to inaccuracy of the value of equivalent series resistance for different operating conditions. Pole-splitting by a nested-miller capacitor can also increase the stability of circuit operations. However, this approach requires a large area, owing to internal compensation and large quiescent current of the regulator as the load current is increased. This work attempts to improve the power supply rejection ratio (PSRR) by using a buffer of ultra-low output impedance with and two stage EAs.

LDO Linear Regulator

The circuit schematic of the conventional linear LDO regulator with the internal buffer is shown in Fig. 1. EA generates an error signal by comparing the reference voltage and feedback signal from a resistive divided output voltage. Several performance issues of the linear LDO regulator must be addressed in terms of line and load regulations, PSRR, load current and dropout voltage. A large voltage gain of the error amplifier is necessary to increase the loop gain for high regulation and PSRR performance [1], which can be achieved by using a large output resistance of the amplifier. According to our results, poles generated by the EA output resistance and parasitic capacitance of a pass transistor might cause system instability and, correspondingly, a large value of output capacitor with proper equivalent series resistance, which deteriorates the bandwidth of the regulator.

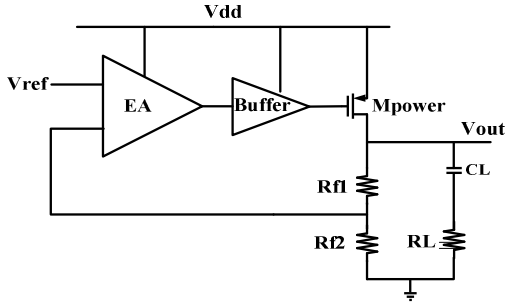

Fig. 1 Conventional linear LDO regulator using buffer compensation. (EA: Error amplifier)

The buffer circuit is added of the EA output it is shown in Fig. 1 [3]. By using two pairs of a parallel circuit, low output impedance can be achieved for frequency compensation, subsequently allowing the transient response to enhance low voltage applications, as shown in Fig. 2 (a). The small signal circuit is shown in Fig. 2 (b). This buffer contains two shunt feedback loops: on composed of M1 and M2, and other composed of M1-M2-M3. The output resistance of the proposed buffer $r_{o,Buf}$ is show as ,

$$r_{o,Buf} \approx \frac{1}{g_{m1}g_{m2}r_{o1} + g_{m1}g_{m3}g_{m4}r_{o1}r_{o3}} \tag{1}$$

The buffer prevents the circuit from operating in such an unstable condition by using its low input capacitance and output resistance characteristics. A dominant pole P_1 consists of output load capacitor C_L and equivalent output resistance R, which can be obtained as [$r_{o,mp} \parallel (R_{fb1} + R_{fb2}) \parallel R_{load}$], where $r_{o,mp}$ is the output resistance of the error amplifier. The second pole P_2 is generated from output resistance of the error amplifier $r_{o,ea}$ and capacitance, which results mainly from input capacitance $C_{i,buf}$ of the buffer. The third pole P_3 is generated from buffer output resistance $r_{o,buf}$ and parasitic capacitance C_p of the large size pass transistor. These three poles can be obtained as,

$$P_1 = \frac{1}{2\pi R_{out} C_L} \qquad P_2 = \frac{1}{2\pi r_{o,ea} C_{i,buf}} \qquad P_3 = \frac{1}{2\pi r_{o,buf} C_p} \tag{2}$$

The non-dominant pole need to very large, which let phase margin can be steady state operation. The gain of the error amplifier is shown in Fig. 3 (a). From the transient analysis to observe, when Vdd from 1.8V to 3.0V, rise time (R) and fall time (F) are both 10ps. The output voltage difference will not exceed 0.03V. The Vdd change with transient (R, F = 10ps) is shown in Fig. 3 (b). The Vout change with transient (R, F = 10ps) is shown in Fig. 3 (c). If the R and F are both 4μs, its output voltage difference will not exceed 0.06V, either. The Vdd change with transient (R, F = 4μs) is shown in Fig. 3 (d). The Vout change with transient (R, F = 4μs) is shown in Fig. 3 (e). Therefore, two EAs of added buffer circuit can improve PSRR. Then LDO circuit diagram is shown in Fig. 4.

Simulation results

Above experiments are list in Table 1(a) and 1(b). Simulation results indicate that, when the supply voltage ranges from 1.8V to 3V, the output voltage can be held at 1.27V, as shown in Fig. 5 (a). Consequently, the output voltage is stable and independent of supply voltage. By the

definition PSR=$V_{dd}=\frac{V_{out}}{V_{dd}}$, PSRR=$\frac{A_d}{A_{dd}}$, this circuit of PSR = -60dB is shown in Fig. 5 (b), and PSRR is more than 60dB which that is better than [3] and [4] is obtained. The LDO linear regulator is implemented in a 0.18-μm double-poly five-metal CMOS process. The layout chip area of LDO linear regulator is 21.5 μm× 42.6 μm as shown in Fig. 6.

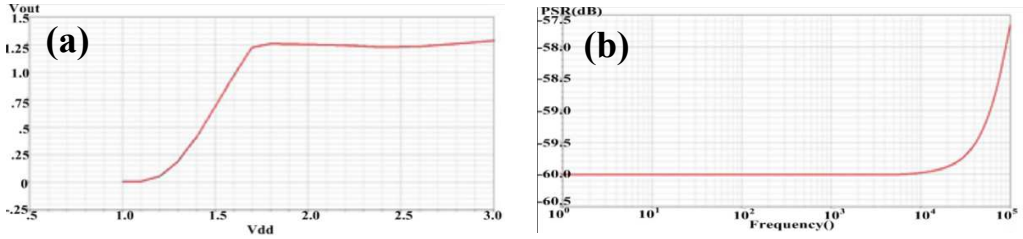

Fig. 5 (a) The output voltage at supply voltage 0V to 3V. (b) Measurement results of PSR.

Conclusions

In summary, this work demonstrates the feasibility of combining ultra-low output resistance buffer and two-stage amplifiers for LDO applications. Simulation results indicate that the high PSRR, stable output voltage and the circuit's PSRR is higher than 60dB, which is better than [3] and [4] obtained in this study. In addition to reducing the layout area, the proposed low dropout regulator linear regulator can add capacitors, which are needed based on the bandwidth. The circuit is designed and fabricated in a TSMC 0.18μm CMOS technology.

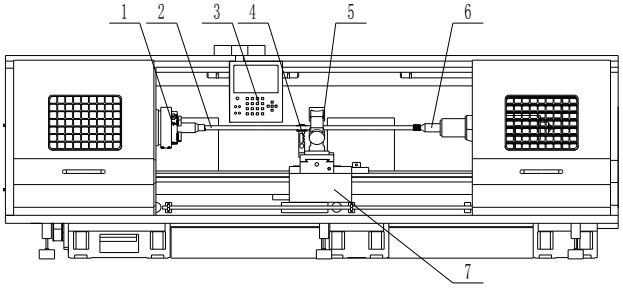
Abstract. A numerical control transformation （NCT）system for a conventional lathe machine is introduced in this paper. The NCT system is considered as the key equipment to the manufacture of the transmission shaft. According to the construction feature and technological requirements, both the hardware and software construction are analyzed, as well as the implementation method of the NCT system. By practical operation, the experiment test result is given at the end of the paper to support the usefulness and practicality of the NCT system.

Introduction

The transmission shaft is one of the key parts of engineering vehicle, by which the power transmission is completed from engine to wheel hub, bearing larger twisting and rolling load [1]. Therefore, the improvement of the transmission shaft hardness is crucial to improve the surface mass density and surface finishing [2]. Although the rolling and strengthening process processes have a long history and laggard implementation of conventional and ordinary lathe machines. This situation lead to high labor intensity, low machining efficiency and long measurement cycle, so a numerical control transformation from conventional lathe to highly automated rolling machine is under badly need[3].

Description of the control objective

The construction of the rolling machine tool is shown in fig.1. The rolling machine is transformed from a conventional lathe machine. The transmission shaft 2, to be rolled, is stuck within the spindle 1 and goes through the center for the rolling head. By using the operating panel 3, the carriage 7 carries the rolling head 5 moving along the horizontal direction while the hydraulic pressure is engaged to the rolling head by hydraulic system. At the same time, the laser displacement sensor 4 in rolling process will carry out a measurement of the part size both before and after the rolling process.



1-Spindle C） 2-Transmission shaft 3-Operating panel 4-Laser range sensor
5-Rolling head 6- Hydraulic tailstock 7- Carriage
Fig.1 Construction of the Rolling Machine Tool

The process parameters of the rolling will be preserved and analyzed through the process database system. According to the reinforcement processing characteristics and manufacture feature of the rolling transmission shaft, there are two kinds of rolling head 5, the rod rolling head and the gear rolling head, which are used differently according to the rolling position of the transmission shaft.

The transmission shaft has a centrosymmetric structure and each end of the transmission shaft is the transitional arc from the rod to the gear. By crossing the rod, the rolling head goes from the gear at left to another at right. According to the process demand, the hydraulic pressure is dynamic-adaptive changed according to the dimensional size of the transmission shaft, which rises up a high precision and swift response control demand both on hydraulic servo control and the displacement measurement, as well as the motion control.

Hardware technique scheme

The NCT system is based on Turbo PMAC (Programmable Multi-Axis Controller), which is the product of Delta Tau Data System Inc. It is and the key part of the whole control system and the representative for open CNC system .The NCT system consists of embedded PLC control system, hydraulic control system ,measurement and data acquisition system, process database system; The Machine tool carriage goes along the X axis direction, spindle rotation is around the C shaft, hydraulic control system outputs accurate pressure value according to the demand of rolling process, control and measurement system of acquisition of transmission shaft parts will get surface size parameters, by detecting the diameter deviation of the transmission shaft before and after the rolling. At last, the rolling process of each parts of various process parameters will be transmitted to the remote process database server.

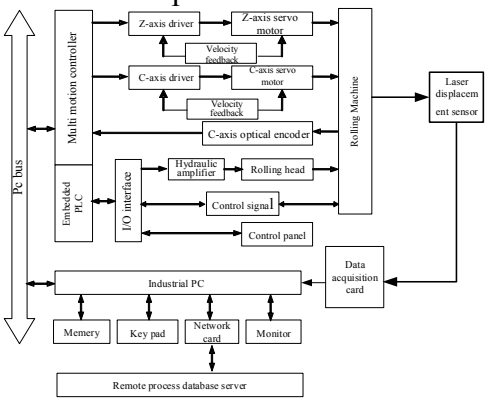


Fig. 3 The hardware principal of the NCT system

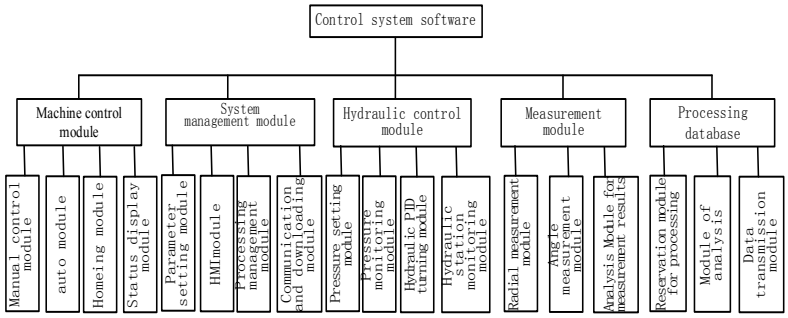

Fig.4 Schematic software construction

Motion control system consists of multi motion controller, I/O interface, servo motor, optical encoder, travel switches and other parts. It is the core of the rolling machine tool, which is responsible for the motion control, the interpolation between Z and C axis, encoder signal input and output, tooth rolling dividing control etc...

Embedded PLC control system is the core of the logical control of the rolling machine tool including digital I/O, A/D, D/A conversion function and the processing of the feedback signal, electromagnetic valve, hydraulic tailstock etc...

The hydraulic control system is composed of PID control algorithm, analog input and output card, servo amplifier, hydraulic servo module, hydraulic pipeline, hydraulic pump station, and rolling head[3]. It provides constant oil pressure within certain process section, and the pressure will also change swiftly from one dimension to another. To realize this swift and constant hydraulic pressure adjustment a pressure sensor is installed within the rolling, and giving the pressure feedback to the hydraulic control system. Under the precise pressure control, the rolling head generates corresponding force upon the transmission shaft, leading to a better surface density.

The diameter and the rotation angle of the transmission shaft, which are measured by the laser displacement sensor and optical encoder respectively [4-5], is considered to form a real-time section of the transmission shaft, which is shown in Fig.5-(a).The final process data can be determined, considering the section as well as the transmission shaft part size and location characteristics, by the remote process database system. Under the construction of the process data, the start point of the rolling, the specific pressure of each section and the rotation speed are all confirmed and applied intelligently [6-7].

Software of the NCT system

Object-oriented and modular programming technology are adopted during the control system software development which is based on Windows XP operating system. The application program is supported by Delphi 7. The structure of the system software is shown in figure 4. The software system includes five main modules: machine control module, system management module, hydraulic control module, measurement module, processing database.

Machine control module is responsible for all precise motion control functions, such as axis interpolation, acceleration and deceleration, etc... Status of servo system and hydraulic system can be monitored in this module in real-time.

System management module is mainly responsible for parameter settings of rolling pressure, velocity of the linear motion as well as the program file management, such as establishing, deleting, loading and store a program. Some communication functions among control system, multi motion controller and processing database are also integrated within this module.

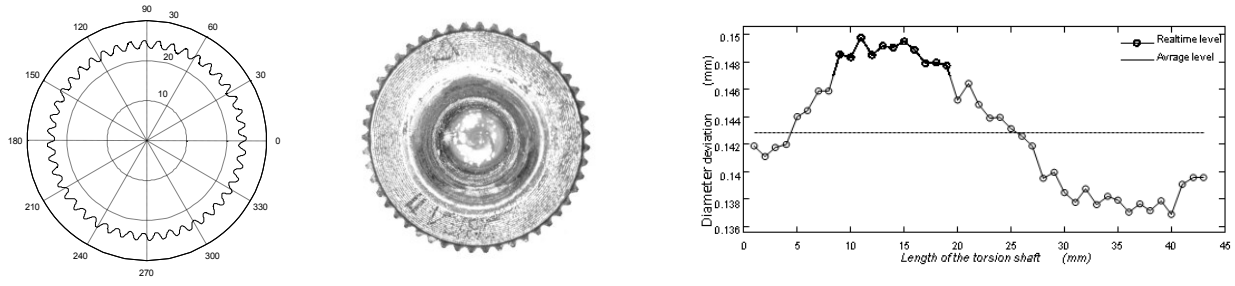
By reading the output of the laser displacement sensor, the detection of the diameter changes can be obtained according to the angle that measured by optical encoder [8-10]. Also by this way, the cross section feature of the transmission shaft will be transferred into the industrial computer, which is shown in fig.5 (a). Under the help of the processing database, the processing parameters, such as the start point, endpoint, and adjustment of the rolling pressure will be calculated and confirmed by the control system software.

The hydraulic module makes a real-time controlling and monitoring to the rolling pressure. It is deigned to be every sensitive to maintain the continuation and stability by the PID turning algorithm embed within the multi motion controller. When the process data is changed, the rolling pressure will be changed intelligently and quickly according to the process data.

ACCESS format is applied in the database development, in which the part number, part dimension (before and after processing), processing capacity, processing date information are included. All the information to be analyzed and reserved will be uploaded to the remote database by TCP/IP protocol, every time the rolling is finished.

Rolling test

With the diameter of 45.84mm, the number of teeth is 44, a transmission shaft is rolled by the rolling machine tool with the control system. The sampling frequency is 10 kHz, 12450 coordinate points are gathered every rotation by the measurement module with time-consuming 1.25s. The measurement result of the rolling is shown in Fig.5 (1)， and the program data generated is shown in Fig.5 (b)



(a) Cross section of the transmission shaft (b) the diameter change after rolling

Fig.5 Experience result of the rolling

Summary

The NCT system is the combination of the numerical control technology, servo hydraulic technology, laser detection technology, database programming technology. The rolling of transmission shaft is implemented the by interpolation of C axis and Z axis, servo control and adjustment of the hydraulic pressure is carried out by PID auto turning algorithm.

The reconfigurable rolling module is used to meet the demand of rolling to different parts of a transmission, the surface of the rod, the transitional arc between the rod and the gear and the teeth of the gear. The whole control system is with high degree of automation, extension and easy system. By using the control system, the intelligent transmission shaft rolling is realized, the system is easy to extend, the efficiency of rolling process is also improved dramatically.

Keywords: rotor system; local rubbing fault; Teager-Huang transform; fault diagnosis

Abstract. An analysis method based on Teager-Huang transform for rotor local rubbing fault diagnosis is introduced. Firstly, the original vibration signal is decomposed into some Intrinsic Mode Function (IMF) components by using Empirical Mode Decomposition (EMD) approach, secondly, Teager energy operator is applied to estimate the instantaneous amplitude and instantaneous frequency of each IMF component, so the time-frequency distribution of the signal is obtained. The rotor local rubbing fault is simulated on a rotor test rig. The analysis results show that this method compared with Hilbert- Huang transform (HHT) can track the occurrence of rotor local rubbing fault better and can extract the characteristics of rotor local rubbing fault effectively. It provides a reliable method for timely and accurate diagnostic to the rotor local rubbing fault.

Introduction

With the requirement of high speed and efficient to rotating machinery, space between the rotor and stator is smaller and smaller. It often happens rubbing accidents between the rotor and stator, therefore, it is important to extract the fault feature of early local rubbing rapidly and to diagnose the rotor rubbing early. It is significant to diagnose the rotor local rubbing which occurs before the full rubbing.

Rotor rub impact signal is nonlinear, non-stationary. Some non-stationary signal processing methods such as: wavelet analysis [1], Hilbert-Huang transform [2], singular value decomposition [3] are widely applied in extracting the rubbing fault feature. The Hilbert-Huang method is a common rub impact fault characteristics time-frequency analysis method. It is composed of two parts EMD and Hilbert transform. EMD can decompose the signal into some IMF and Hilbert transform can solve the instantaneous amplitude and instantaneous frequency of each IMF component, but the Hilbert transform itself has endpoint effect, and can produce meaningless negative frequency [4].

Teager-Huang transform bases on Hilbert-Huang transformation. It combines the EMD and Teager energy operator to analyze the vibration signal. EMD can decompose the signal into several IMF components adaptively, then the Teager energy operator gets the instantaneous amplitude and instantaneous frequency of each IMF component [5]. Teager energy operator can reveal the change of instantaneous frequency better from the energy trace point of view, so it is an effective means to monitor the rotor rubbing occurrence and to extract the local rubbing feature.

Fundamental of Teager-Huang transform

The EMD method. This method of Huang et al.[6] to extract such IMFs is a pure algorithmic method. Candidates for an IMF are extracted by first computing the upper $u(t)$, and lower $v(t)$, envelopes via a cubic spline interpolation from the maxima and minima of $x(t)$. Then the mean envelope is obtained by computing $m(t)=[u(t)+v(t)]/2$ and finally the candidate by $r_1(t)= x(t)-m(t)$. Generally, r_1 does not fulfill the properties of an IMF. A good candidate can be reached by iterating the same process to r_1 and the subsequent r_k. The final retained IMF is $x_1(t)= r_n(t)$. Then the next IMF is obtained by the same algorithm applied on $x(t)- x_1(t)$. The remaining IMFs can be computed by repeating this algorithm on the successive residues.

Teager Energy Operator(TEO). Because TEO is high demodulation precision and high speed, in recent years, it is widely used in the instantaneous frequency and instantaneous amplitude analysis [7], the definition of TEO for continuous signal:

$$\psi[x(t)] = [\dot{x}(t)]^2 - x(t)\,\ddot{x}(t) \tag{1}$$

$x(t)$ is the original signal, $\dot{x}(t)$ and $\ddot{x}(t)$ are the first derivative and the two order derivative.

To discrete signal, TEO can be defined as

$$\psi[x(n)] = x^2(n) - x(n+1)x(n-1) \tag{2}$$

From the calculation of Eq.2, TEO requires only three sampling points every time, literature [7] analyzed the singe AM-FM signal by TEO. The instantaneous amplitude and instantaneous frequency:

$$f(n) = \frac{1}{2}\arccos[1 - \frac{\psi[x(n+1) - x(n-1)]}{2\psi[x(n)]}] \tag{3}$$

$$a(n) = \frac{2\psi\,[x(n)]}{\sqrt{\psi[x(n+1) - x[n-1]]}} \tag{4}$$

TEO compared with Hilbert transform has no complex number calculation, so its calculation amount is very small. It can quickly track the change of the amplitude and frequency of signals, and can reveal the instantaneous frequency mutation better.

Teager-Huang transform. The original signal can be decomposed into a series of IMF components through the EMD method, then calculate the instantaneous amplitude and instantaneous frequency of each IMF by Eq. 3 and Eq.4, so the time-frequency expression of the original signal is:

$$T(w,t) = Re\sum_{i=1}^{n} a_i(t)\exp^{j\int w_j(t)dt} \tag{5}$$

According to Eq.5, the time-frequency diagram and time-frequency-amplitude three-dimensional diagram can be constructed to reveal the signal time-frequency characteristic.

Rotor Local Rubbing Fault Analysis

When the rotor local rubbing occurs, the speed is unstable. The time frequency distribution characteristics assume the regular fluctuation along the base frequency. The mutation moment of instantaneous frequency is corresponding to the deformation point time in the time domain waveform, also this is the moment of the local rubbing occurrence. As the continuous rubbing process, the base frequency component changes acutely in the time frequency diagram at the late rubbing stage, at the same time the low frequency and high frequency appears.

The local rubbing simulation experiment is done at 3300r/min speed by Bently RK-4 rotor test rig. Two electrical vortex sensors are set up at the single plant's two sides to get the radial direction displacement vibration signal. The copper rubbing thimble is fixed in a place which has a small separation from the shaft. Sampling Frequency is 5120Hz. The analysis time is 60.4s.

Because the gathering data is large, the paper re-samples every 10 point to analyze, so the analysis frequency is 512 Hz. For tracking the whole process of rotor local rubbing, the time course is divided into three stages: the occurence stage, the early stage and the late stage.

The occurrence stage of rotor local rubbing impact. Analysis the 0-16s' data, the time domain waveform is shown in Fig. 1(a), it shows the signal amplitude distortion at the 9 second. Fig. 1(b) shows Teager-Huang transform analysis, it indicates the instantaneous frequency mutation at about the 9 second too, the low frequency and high frequency appears. Fig.1(c) is the time-frequency-amplitude three-diagram which shows the same result. Fig.2 is the analysis result by HHT, it doesn't show the instantaneous frequency mutation clearly when the rotor rubbing occurs. So

Teager-Huang transform can track the instantaneous frequency mutation better then HHT, and it can be used in the online rotor monitor and diagnosis.

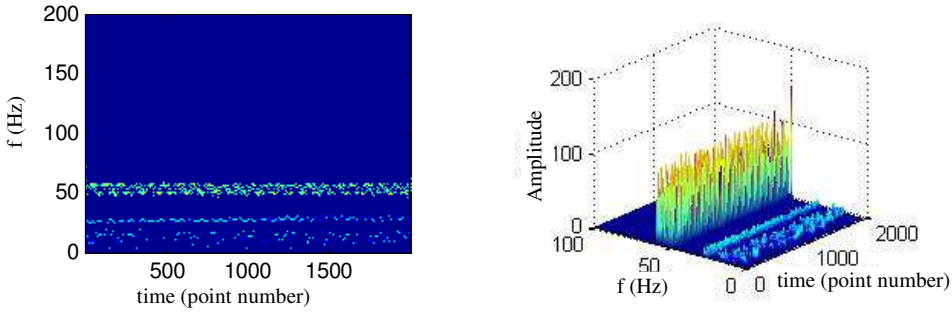
Fig.2 The occurrence stage analysis by Hilbert -Huang transform

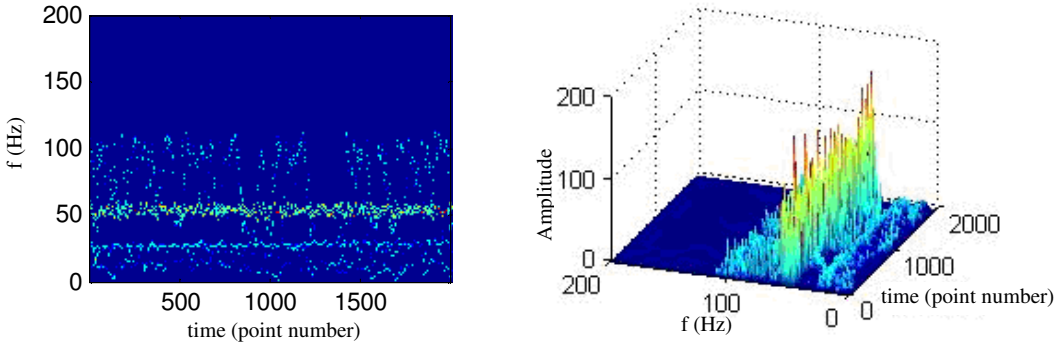
The early stage of rotor local rubbing impact. The paper analyzes the rubbing data of 17-19.9s by Teager-Huang transform. Fig. 3(a) shows the time frequency distribution. Fig. 3(b) shows the time-frequency-amplitude distribution. They show that the rubbing signal characteristic appears evident regular fluctuation, and the 1/2, 1/3 frequency components appear, all of this reflect the characteristics of early local rubbing.



(a)time-frequency diagram (b)time-frequency-amplitude dimensional

Fig.3 The early stage analysis by Teager -Huang transform

The late stage of rotor local rubbing impact. The paper analyzes the late stage rubbing data of 56-59.9s by Teager-Huang transform. Fig. 4(a) shows the time frequency distribution. Fig.4(b) shows the time-frequency-amplitude three-diagram. They show the frequency components of this stage is more complex and the rubbing signal characteristic appears more high frequency besides the 1/2, 1/3 frequency components . The amplitude increases compared with the early stage, it assumes rotor vibration is more complex and acutely.



(a) time-frequency diagram (b) time-frequency-amplitude dimensional

Fig.4 The late stage analysis by Teager -Huang transform

Conclusion

The paper introduces the fundamental of Teager-Huang transform firstly, also simulates the rotor local rubbing fault at the constant speed condition through the Bently RK-4 rotor test rig, then analyzes the local rubbing process data by Teager-Huang transform. The results show this method can track the rotor local rubbing occurrence, development better, and can extract the rotor local rubbing fault feature effectively. It provides important method for the rotor local rubbing fault diagnosis.

Keywords: Grinding; Multiple-grain cutting; Finite element method (FEM); Smooth particle hydrodynamics (SPH); Cutting Force.

Abstract. A multiple-grain cutting model is developed to simulate the grinding process for rolled homogeneous armor steel (RHA) 4043 using a coupled three-dimensional (3-D) finite element (FE) - smoothed-particle hydrodynamics (SPH) approach in the research. The proposed numerical model is then employed to investigate interactions and interferences among the grains at high speed cutting. The numerical results show the cutting forces and pile-ups of chips are greatly influenced by these interactions and interferences during the cutting process.

Introduction

Grinding is a commonly-used material removal processes using grinding wheel as cutting tool and employed as a finishing process in machining for shaping workpieces with high precision. The grinding wheel is an expendable wheel and composed of an abrasive compound used for various grinding and abrasive machining operations. These particles are termed as abrasive grains at a large number and their size and distribution are very random and therefore it makes the grinding process a very complex machining process to be studied. For simplicity, the cutting process of a single grain has attracted research interests using both numerical and experimental means, which becomes a precursor to understand the entire grinding process. However in reality, the single-grain cutting process is not easy to be studied using traditional experimental approaches because the grain is too tiny at micro scale. Therefore, numerical modelling and simulation techniques have been widely used for simulating the single-grain cutting process, including kinematic approaches, finite element analysis and molecular dynamics, etc.[1] and among them, the finite element method (FEM) is the most powerful tool for simulating cutting processes [2][3]. The smooth particle hydrodynamics (SPH) method is also used, which was originally developed for problems in astrophysics and now it is used in fluid and continuum mechanics.

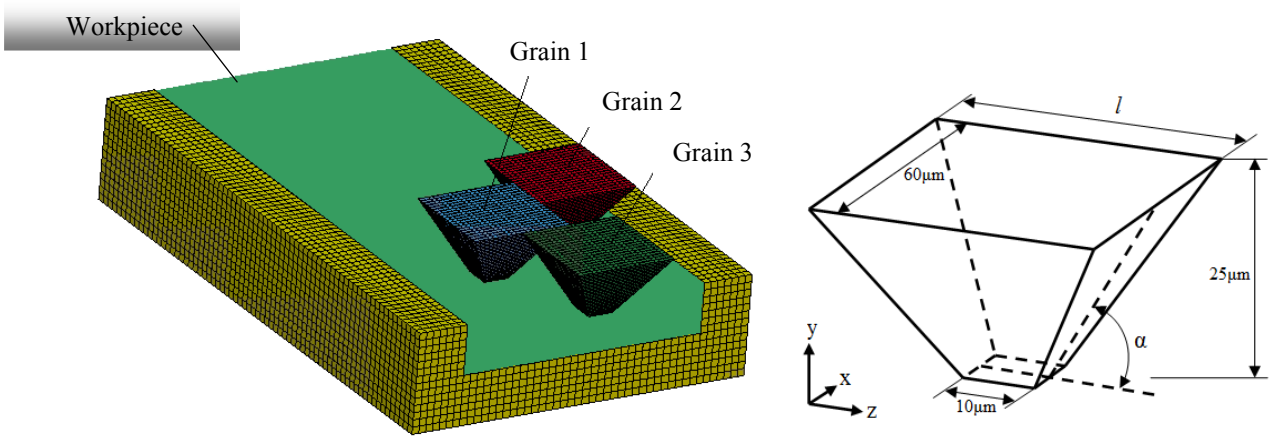
Doman et al. [3] developed an experimentally validated finite element model with the Lagrangian method for the rubbing and ploughing phases as precursors to the cutting phase in scratch tests. Also using the Lagrangian method, Öpöz and Chen[4] conducted a 3-D simulation of single grain grinding with the adaptive remeshing technique for the rubbing and ploughing phases. Su et al. [2] conducted a simulation of single grain cutting based on fluid-solid interaction method, in which the grain was modeled by Lagrangian meshes while the workpiece was modeled by Euler meshes. In the work of Anderson et al.[5], a finite element model combined the Euler and Lagrangian methods was developed in which Euler meshes were implemented in large deformation zones while Lagrangian meshes were used in others. Villumsen et al.[6] introduced a simulation approach on metal cutting using the SPH method and Niklaus et al.[7] conducted a simulation of single grain cutting using the SPH method to investigate influences of grain geometry, grain orientation and grain placement on cutting forces, burr

generation and chip removal rates. Recently a coupled 3D FE-SPH model of a single-grain cutting process for the grinding on RHA 4043 was developed by authors [8], focusing on influences of grain negative rake angle as well as high and super-high cutting speeds from 100 m/s to 260 m/s.

In this study, based on authors' previous work on single-grain model, a three-dimensional (3-D) numerical model of the multiple-grain cutting, using the coupled Lagrangian finite element (FE)-smoothed particle hydrodynamics (SPH) approach, is developed for the high speed grinding of RHA 4043 workpiece. The multiple cutting grains are modelled as several truncated pyramids, which can be made with cubic boron nitride (CBN) abrasive materials. The developed numerical model is employed to investigate the interactions and interferences of grains during the grinding process. The results extracted from the proposed model mainly include the cutting force and chip formation.

Coupled FE-SPH Model for Multiple-grain Cutting

In the current study, the multiple-grain cutting model was idealised as a RHA 4043 workpiece (160 μm in length, 200 μm in width and 40 μm in height) and three CBN cutting grains as shown in Fig. 1 (a). The single grain was treated as a truncated rectangular pyramid which is made of cubic boron nitride (CBN) abrasive materials.



(a) (b)

Fig. 1 The multiple-grain cutting model

In high deformation zones close to contact zone between the workpiece and the grains, the SPH method was implemented in the central part of the workpiece as a cuboid of 160 μm × 120 μm × 20 μm with fully taking advantage of this method. The benefits employing the SPH method include a fracture criterion is not required to initiate chip formation since the workpiece material defined by SPH particles will naturally flow around these cutting grains and also adaptive meshing which is usually implemented in cutting process using the Lagrangian method is avoided. In the regions relatively far from the contact zone, since the deformations are relatively small, the Lagrangian finite element method was implemented for the rest zones in the workpiece and the grains using 8-node solid hexahedral Lagrangian elements. The coupling between Lagrangian elements and SPH particles was achieved using "automatic nodes_to_surface" contact type where the slave part was defined with SPH particles and the master part was defined with the Lagrangian elements [10]. Also considering the symmetry of the model, only a ½ model was used to reduce the computational costs. The SPH zone has a mesh density of 512×10^6 nodes/mm^3.

The geometry of the CBN abrasive was captured under the scanning electron microscope (SEM) in literature [8] and the mathematical model of a single grain is the truncated pyramid and its dimensions are shown in Fig. 1 (b), which can be treated as elastic. The single grain model has an adjusted dimension – its length l, which can be varied to get different values of negative rake angle α of interest. In the numerical simulation, the grain was moved along the positive direction of the z-axis in a defined moving path depicted in Fig. 2.

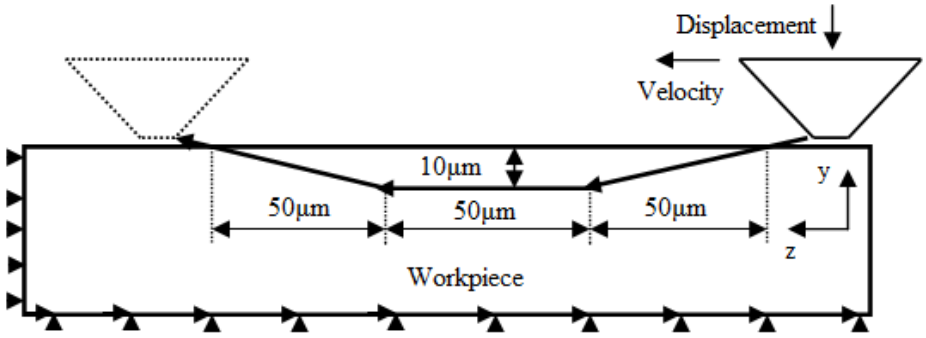


Fig. 2 Grain cutting path and boundary conditions in the numerical model

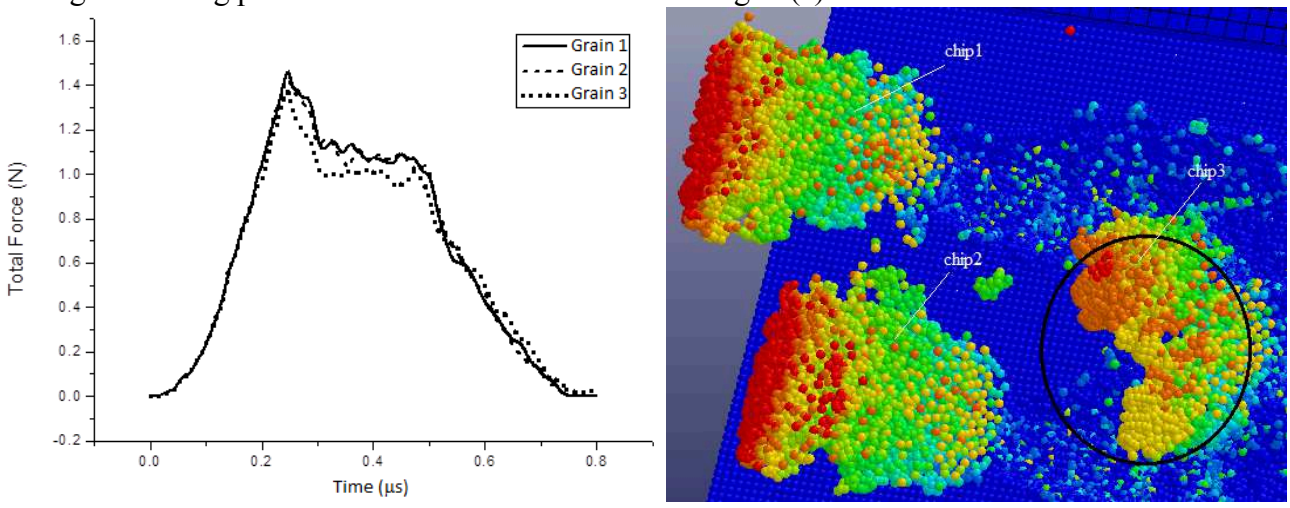
To model the mechanical behaviours of RHA 4043 steel at high strain rates and material softening caused by plastic heating, the Johnson-Cook material model was chosen for the workpiece and its general form is given as

$$\sigma_y = \left[A + B\left(\varepsilon_p\right)^n\right]\left(1 + C\ln\frac{\dot{\varepsilon}_p}{\dot{\varepsilon}_{p0}}\right)\left[1 - \left(\frac{T - T_0}{T_m - T_0}\right)^m\right] \quad (1)$$

where σ_y is the material yield stress, ε_p is the effective plastic strain, $\dot{\varepsilon}_p$ and $\dot{\varepsilon}_{p0}$ are the effective plastic and reference strain rates, and T, T_0, T_m are the current, ambient, and melting temperatures, respectively. A, B, n, C and m are materials constants. The main parameters in this model were adopted from literature[10].

Results and Discussion

A series of simulations were conducted to investigate the interactions and interferences among the cutting grains. The grains were set with a same negative rake angle of -31° and moving at the same cutting speed of 200 m/s. The total simulation time was set as 0.8 μs. Total forces of all three grains during the cutting process were obtained and shown in Fig. 3 (a).



(a) (b)

Fig. 3 Total force and chip formation at each grain from 3-D simulations

In the model, Grain 2 was arranged right to Grain 1 while Grain 3 was just behind these other two. Grains 1 and 2 have much closer results during the cutting process compared to Grain 3 since these two grains are located in the upstream. These two grains influence each other almost at the same level. However the comparisons between Grain 3 with other two are more interesting and there are three stages identified: 1) $0 < t < 0.18$ μs, total forces have no difference with each other as Grain3 was not influenced by other two and still out of the affected region; 2) $0.18 < t < 0.55$ μs, Grain3 began to

reach the heat-affected zone where the workpiece material was softened by a large amount of heat generated by Grains 1 and 2. The material became much easier for Grain 3 to cut and thus the cutting force from Grain 3 was much lower than the other two; and 3) $t > 0.55$ μs, in this last stage, all grains finished the cutting on the workpiece and cutting forces were all dropped dramatically meanwhile the generated heat undergone a rapid decrease too.

The chip generation was also checked during this multiple-grain cutting process as shown in Fig. 3 (b). Pile-ups generated by Grains 1 and 2 were found ahead of Grain 1 while the softening was decreased, thus the cutting force of grain1 became larger than those from Grains 2 and 3. In addition, the interferences on chip generation have been found in the cutting process. Chips generated by Grain 3 were squeezed to fracture.

Summary

In this study, a 3-D multiple-grain model has been devised for modelling a high speed grinding using the coupled FE-SPH approach to investigate the interaction and interferences among the grains during the cutting process. Numerical results show that cutting force variation of these grains can be divided into three stages to show such interactions and interferences. When the subsequent grain is in the heat-affected zone and the workpiece material is softened by heat, the cutting force of the subsequent grain becomes much lower than those of the forward ones.

Keywords: switched reluctance motor, sensorless control, variable thresholds, position estimation error

Abstract. To realize starting operation and reduce position estimation error of switched reluctance motor(SRM) without position sensor, a novel control method based on pulse injection, divided angle section and variable threshold is presented. The starting operation of SRM can be accomplished by injecting high frequency pulse and judging position sectors. Variable threshold is used to reduce position estimation error. The value of threshold is obtained by looking up table prestored in controller. The method avoids complicated mathematical model and is suitable for starting operation with two phases. Besides, rotor position estimation error of this method is analyzed and the method which can decreased the error is proposed. At last, the experiment has been done to verify the performance of the control method.

Introduction

Switched reluctance motor (SRM) has received widespread attentions on account of its good speed performance and fault tolerance. The using of position sensor, however, increases the system cost, reduces the reliability of the system and limits the range of application of SRM. Therefore, the development of reliable and low cost sensorless control method is quite necessary. To realize the sensorless control of SRM, a method based on pulse injection, position sectors divided and variable thresholds is proposed. The way of pulse injection is suitable for SRM at starting and low speed[1]. Divided sector simplifies the estimation of position[2-3]. The estimation error can be decreased by means of variable thresholds. Experimental results testify the advantage and feasibility of the method.

The Principle Analysis of Position Estimation Method

The Base Principle of Pulse Injection and Position Sectors Divided. The position of traditional SRM is detected by means of using a number of photoelectric tube installed on motor stator and a toothed plate installed on the rotor. The photoelectric tube outputs the logic value accordingly as long as the motor rotates. The controller receives the logic value and judges which position sectors the motor is located at. Thus, the electrical degrees of position is divided into several sectors. The controller receives the logic value of position sensor to judge the position sectors of the motor. The motoring phase changes according to the change of position sector.

the phase voltage equation of SRM can be expressed as

$$U_{dc} = Ri + L\frac{\mathrm{d}i}{\mathrm{d}t} + i\frac{\mathrm{d}L}{\mathrm{d}\theta}\omega \quad (1)$$

Here, U_{dc} is the bus voltage, $dL/d\theta$ is the change rate of phase inductance, ω is the angular speed.

With three-phase motor, for example, when the SRM is still, the high frequency voltage pulse is injected into three phase winding. Because the motor is static and the frequency of voltage pulse is very high, the amplitude of responding current is small. SRM does not rotate. The counter

electromotive force(EMF) and voltage drop of phase resistance can be neglected. the phase voltage equation can be simplified as

$$U_{dc} = L\frac{\mathrm{d}i}{\mathrm{d}t}. \tag{2}$$

From Eq. 2, the responding current value can be derived as

$$di = U_{dc}dt / L(\theta). \tag{3}$$

For discretization Eq. 3, the magnitude of current can be expressed as

$$\Delta i = U_{dc}\Delta t / L(\theta_0). \tag{4}$$

Here, Δi is the magnitude of responding current, $L(\theta_0)$ is the value of inductance at initial position θ_0, Δt is the pulse duration.

From Eq. 4, it can be found that the amplitude of responding current is inversely proportional to the value of phase inductance[4]. So the phase inductance can be determined according to the responding current amplitude. The phase inductance value of motor is in accordance with the electrical position. These are shown in Fig. 1.

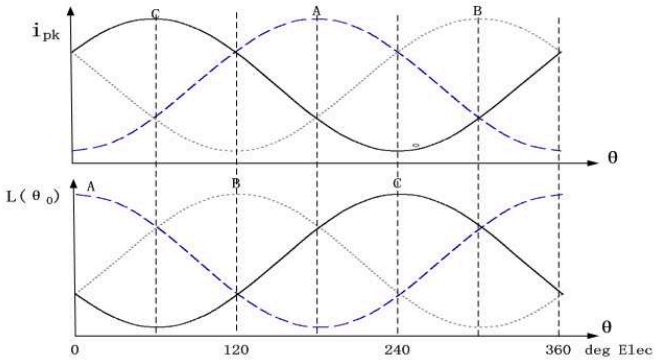

Fig.1 The value of responding current and phase inductance.

So, the position sectors of SRM can be determined by comparing the value of responding current with the thresholds which are used to distinguish the rotor position of SRM.

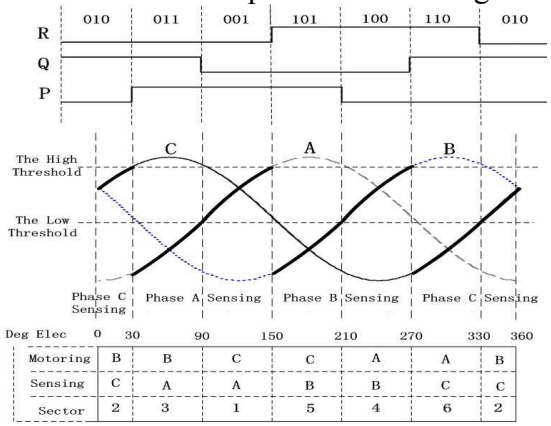
Rotor Position Estimation at Starting and Low Speed. The starting algorithm for the sensorless operation has to be able to run the machine from any initial condition. To do so, the power converter is used to inject current pulses simultaneously on all three phases of the SRM. The rotor position can be obtained based on a comparison of the pulse amplitudes and the two thresholds[5]. Table 1 summarizes the comparison algorithm. For example, if the initial position of SRM is located at the sector 3, the pulses are injected into all three phases of the SRM simultaneously to detect the position, the relative amplitude of the three phase pulses will be that: the pulse amplitude of phase A is lower than The Low Threshold, the pulse amplitude of phase B is also lower than The Low Threshold and at the same time the pulse amplitude of phase C is higher than The High Threshold. By looking up Table 1, it can be judged that the position is located at sector 3. The operation in sector 3 is phase B motoring and phase A sensing. After that, the starting of SRM will be realized.

Table 1: Sector in function of pulses amplitudes

sector		Phase A pulse amplitude	Phase B pulse amplitude	Phase C pulse amplitude
3	Phase B Motoring Phase A Sensing	$I_A<TL$	$I_B<TL$	$I_C>TH$
1	Phase C Motoring Phase A Sensing	$TL<I_A<TH$	$I_B<TL$	$TL<I_C<TH$
5	Phase C Motoring Phase B Sensing	$I_A>TH$	$I_B<TL$	$I_C<TL$
4	Phase A Motoring Phase B Sensing	$TL<I_A<TH$	$TL<I_B<TH$	$I_C<TL$
6	Phase A Motoring Phase C Sensing	$I_A<TL$	$I_B>TH$	$I_C<TL$
2	Phase B Motoring Phase C Sensing	$I_A<TL$	$TL<I_B<TH$	$TL<I_C<TH$

The algorithm is suitable for any repetition of three-phase machines. For machines with high number of phases, a suitable sector arrangement can be made similar to the three-phase implementation. The value of thresholds will depend on the inductance profile of the machine. After the starting of SRM, the suitable motoring and sensing phases in terms of the sectors are shown in Fig.2. Here, R, Q and P represent the logical value of position sensor in traditional SRM. The bold line represents the responding current which is given by injecting high frequency pulse after starting. The Low Threshold is used to determine when the phase used for motoring has to change. The High Threshold is used to determine when the phase used for sensing has to change.

A summary of the phase selection for motoring and position sensing as functions of the sectors related to the Table 1 sensing and motoring phases rotor position is shown in Fig.2. Fig.3 is the flowchart describing the SRM motoring operation. This algorithm directly depends on the sector information[6]. This information is first generated by the initialization algorithm, and then maintained with the phase selection algorithm.



Motoring	B	B	C	C	A	A	B
Sensing	C	A	A	B	B	C	C
Sector	2	3	1	5	4	6	2

Fig.2 Position sectors and responding currents.

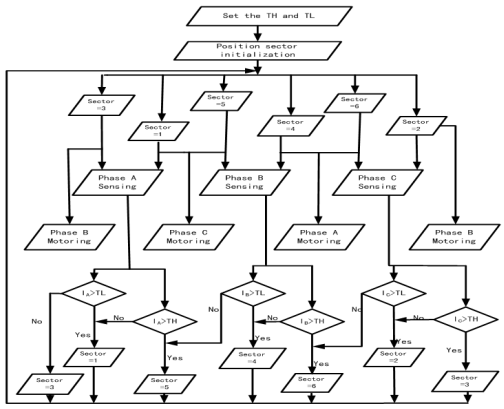


Fig.3 Flowchart of SRM sensorless operation.

The Variable Threshold under the Condition of Different Speed. It can be seen from equation (1) that the pressure drop of the winding and counter EMF are neglected when estimating the position of SRM. Solving the differential Eq. (1), the value of responding current can be derived as

$$i = \frac{U_{dc}}{A}(1 - e^{-\frac{A}{L}t}) \quad . \tag{5}$$

Where, $A = R + \frac{dL}{d\theta}\omega$.

When the SRM starts, the value of back EMF increases with the speed increasing. So the amplitude of responding current will decrease. The position estimation on certain point will have great error if still using the threshold which is setted before. It is illustrated in Fig. 4: ω1, ω2 and ω3 represents the curves of responding current amplitude when the SRM speed are respectively 0rpm, 200rpm, 500rpm. When the speed of SRM is 0rpm, the value of responding current is biggest because of the back EMF is zero. When the speed is 200rpm, the value of responding current decreases. When the speed becomes 500rpm, the value of responding current is smaller than its of 200rpm. The Threshold 1 is assured as The Low Threshold which is used to compare with responding current. Take the speed 0rpm and 500rpm for example, the phase commutation point is $A_1$when the SRM is still. This point can be detected as the 90 deg electrical. But when the speed increases to 500rpm, the phase commutation point will be A'_1 if still using The Threshold 1 as The Low Threshold. At the same time, the controller will take A'_1 as the 90 deg electrical. Actually, A_2 is the phase commutation point which should be obtained by comparing the responding current with The Threshold 2. So it needs to change threshold according to different speed.

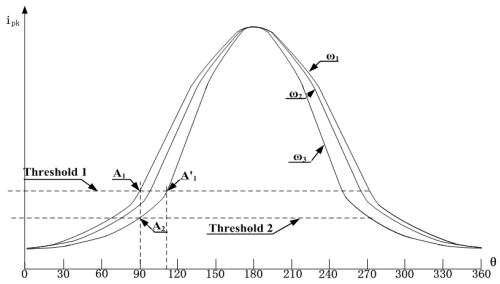

Fig.4 The variable thresholds under different speed.

To decrease the position estimation error caused by speed, a variable threshold method is proposed. The detail procedure is that testing The Low Threshold and High Threshold at different speed and then storing it in a table for controller to look up. The controller chooses different thresholds according to different speed to decrease the position estimation error.

Position Estimation Error Analysis

The machine structure, especially the number of rotor poles, and the inverter switching frequency limit the position resolution and fix the rotor position error. The resolution varies with the operating speed gradually worsening as the speed increases. For an SRM operating at a speed of n rpm and with a pulse injection frequency of pulse, the resolution in mechanical degrees is

$$\theta_{\delta} = \frac{n}{60} \times 360 \times \frac{1}{f_{pulse}} \quad (6)$$

The resolution in electrical degrees for an SRM with N number of rotor poles is

$$\theta_{e\delta} = \frac{n}{60} \times 360 \times \frac{1}{f_{pulse}} \times N \quad (7)$$

It can be inferred from Eq. (7) that with the senseless operation, the maximum position error occurs at the maximum speed of the machine, and the number of poles repetition directly affects the speed range of the senseless method. If the number of pole repetition is low, the senseless method will be able to reach higher speeds. For a pulse injection frequency of 3kHz, a SRM with 6/4 structure, the position resolution is 1.6 deg electrical at the speed of 200rpm and 4 deg electrical under condition of 500rpm. While if the SRM is 12-8 structure, the position resolution will be 3.2 deg electrical and 8 deg electrical. The frequency of pulse injection can be increased to decrease the position error under the allowance of switch devices and Signals to Noise Ratio(SNR).

Experimental Verification

To verify the performance of the control method, the experiments are implemented at a three-phase, 1KW, 6-4, low speed SRM. The base speed of the machine is 1000 rpm with a DC bus voltage 30V. The SRM drive used in this experiment is a classical bridge power converter with the phase winding between the two switches of the same phase. High capability price ratio DSP chip of TMS320F28335 of TI cooperation and CPLD chip of EPM3032 of ALTERA Company are chosen as the digital controllers. The phase current signals are obtained by the hall current sensor ACS750 timely. An absolute encoder is fixed on the shaft of motor to detect the position of SRM. A DC motor is fixed on the output of SRM to drive the SRM with a certain speed. The digital controller stores The Low Threshold and High Threshold under different speed. Hardware of the experimental system is shown in Fig. 5 and Fig. 6.

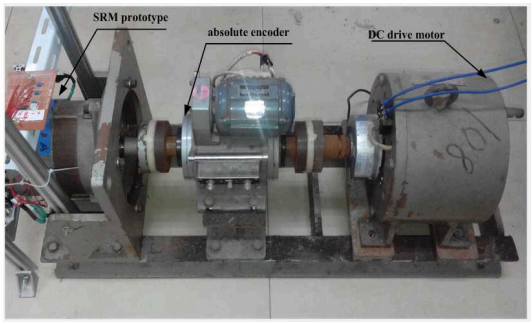

Fig.5 Hardware of the SRM.

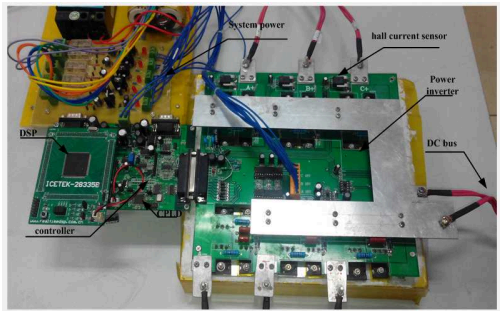

Fig.6 Hardware of control system.

The SRM is motioned by DC motor with a certain speed. At the same time, a high frequency pulse is injected into three phases and the phases give the responding current. The DSP will receive the signal of responding current which has been amplified and filtered. The DSP stores The Low Threshold and High Threshold at 22.5 deg mechanical and 37.5 deg mechanical which can be obtain by absolute encoder. Fig. 7 is a scope screen shot of one phase responding currents and position waveforms of SRM under the speed of 100rpm, Fig. 8 is under the condition of 500rpm. The High Threshold and Low Threshold under different speed is shown in Table2.

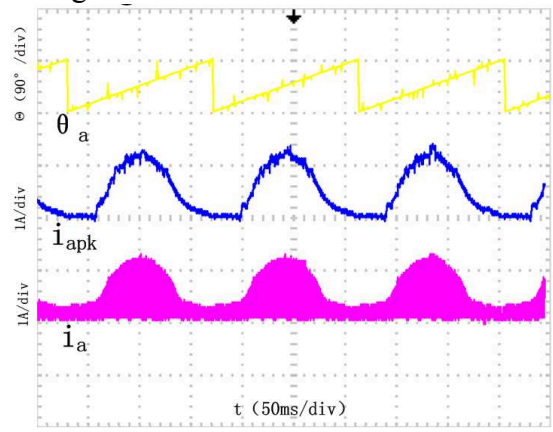

Fig.7 Wave under 100rpm.

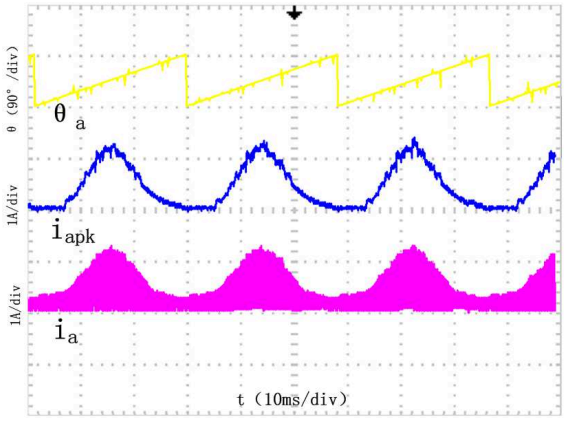

Fig.8 Wave under 500rpm

Table 2 The Low Threshold and High Threshold under different speed

Speed (rpm) / θ_c (deg)	0	100	200	300	400	500	600	700	800	900	1000
22.5°	0.454	0.45	0.448	0.445	0.441	0.439	0.436	0.431	0.427	0.421	0.41
37.5°	1.231	1.229	1.226	1.224	1.221	1.217	1.212	1.205	1.198	1.191	1.182

The position estimation errors under different speed are shown in Fig. 10. It can be seen from the Fig. 9 that the position estimation errors become bigger with the increasing speed of SRM. With the increasing of speed, the number of pulses in one sector becomes less. The resolution of responding current becomes low and the position estimation errors become big.

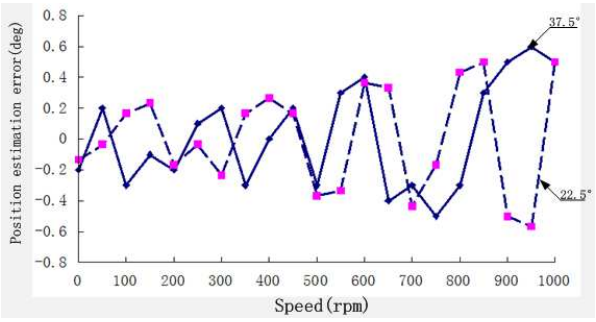

Fig.9 The position estimation errors under different speed

Conclusion

To overcome the starting and position estimation error problems of the SRM without position sensor, a algorithm based on pulse injection, position sectors and variable thresholds is proposed. By using this method, the position estimation error can be decreased and this method needs only the sector of the position instead of the precise position of SRM. The value of High Threshold and Low Threshold is changeable with different speed by looking up the table which is restored in controller and avoids complicated mathematical model. The high frequency pulse is injected in one phase only when SRM runs. It means that the SRM can work in condition with two phase motoring. The experimental results fully verify the proposed senseless scheme and demonstrate its advantages.

Keywords: Corrugated cushion, Static cushioning property, Corrugated paperboard

Abstract. 0940 type cushion of E-flute corrugated paperboard is selected as the research object. By changing the load area, side breadth and the height of the cushions separately, static compression tests were done. The effects of structural parameter to cushioning property were analyzed through energy absorption method. It is useful to promote the application of corrugated board cushion.

Introduction

Since the requirements of "green packaging", when choosing cushion, they takes into account not only rationality of cushion structure and economy of cost, but also the importance of environmental protection of materials. So Compared with the traditional foam packaging materials, paper materials are valued more and more. Due to the light weight, good absorption of impact energy, extending the acting time of shock pulses, easy recycling and low recycling cost, corrugated paperboard gain growing popularity.

There have been many research on cushion property of corrugated paperboard structure. Some scholars in China or abroad have researched on the mechanical properties of different corrugated structures. Bending test of corrugated cushions for both horizontal and vertical on five different structural forms have been done by Myung Hoon Lee [1] . Sek tested the cushioning property of on stacked type corrugated board through dynamic shock [2]. Xu Wencai only tested the dynamic property of two cushioning structural forms of corrugated board [3, 4]. Wang Dongmei researched the static and dynamic properties of corrugated composites on four different structures [5]. In this paper, the author selects 0940 type cushion of E-flute corrugated paperboard as the research object. By changing the load area, side breadth of the cushions separately, static compression tests were done. And The effects of structural parameter to cushioning property were analyzed through energy absorption method. Gain the energy value E of the maximum compressive load by integrating to force-displacement curve getting in the static compression process. Further, its unit volume energy absorption E' is obtained. E' not only considers the effects of all parameters, also meets its cushioning mechanism. Then defines cushion efficiency $\rho = E/F$, and ρ can compare cushioning property under different parameter changes more comprehensively [6].

Experiments

Material and Equipment. Experimental materials: Materials used in the experiment were E-flute corrugated paperboard purchased from SCA (Tianjin) Packaging Products Limited Company, the thickness is 1.8mm, the basis weight is 475 g/m^2. The material surface is clean, no paper defects. The top of test sample is square, the smallest size 100mmx100mm, Max 160mmx160mm, the range of height and breadth both range from30mm to 60mm, and there are 4 parallel samples in each group.

Experimental equipment: Packaging prototype (PRODUCER1317) from Beijing State technology development limited, electronic universal material testing machine (model 3300) from Instron Company of the United States.

Experimental method. In order to study the effects of every parameter on the structure energy-absorbing, the cushioning structure were divided into two groups. The first group, load area(s) is the only variable. The second group, breadth is the unique variable. Height is 35mm constantly. All the parameters are showed as Figure 1. All size of the samples in three groups are showed in Table 1. Every group of the samples includes seven size.

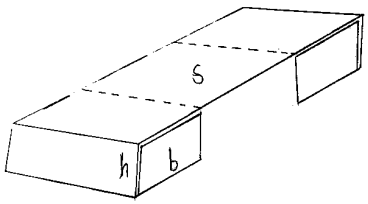

Fig.1 Diagram of 0940 type cushion

Table 1 Sample parameters of the three groups

b=40mm, s(mm^2)	100×100	110×110	120×120	130×130	140×140	150×150	160×160
s=150mm×150mm, b(mm)	30	35	40	45	50	55	60

The experiment was done according to GB 8168 "Testing methods of static compression for package cushioning materials". The test temperature is 23 ℃, relative humidity is 50%. In order to increase the friction to prevent the sliding during the experiment, two pieces of wooden board were fixed to the upper and lower pressing plates separately.

Results and analysis

Effect of load area on cushioning property. The relationships of load area and unit volume of energy absorption, cushioning efficiency, maximum compression loads in first group are shown in the Tables 2 below.

Table 2 Cushioning parameters under different load area

Load area（mm^2）	100×100	110×110	120×120	130×130	140×140	150×150	160×160
Load（N）	1683.83	2004.46	2122.82	2503.48	2301.51	2457.54	2811.50
E（KJ/m^3）	26.5	17.6	23.2	30.9	19.2	14.5	14.1
ρ	7.4	10.6	7.2	11	3.5	3.4	10.6

In order to see the trends of maximum load and energy absorption visually, fit the discrete points in the table 2, the results as shown in Fig.2.

From Fig.2 we can see, as load area increasing, maximum compression load increased, but the energy absorption of unit volume changes irregularly. When area that surrounded by the load and load area increasing, the energy absorption increasing. That is when the sample's deformation appears platform and the maximum compression load appeared at large deformation, the sample cushioning property is the best. So combining data and figure analysis, the energy absorption of unit volume is best while the load area to be 130mm×130mm. The cushioning efficiency of the structure is shown as Fig.3.

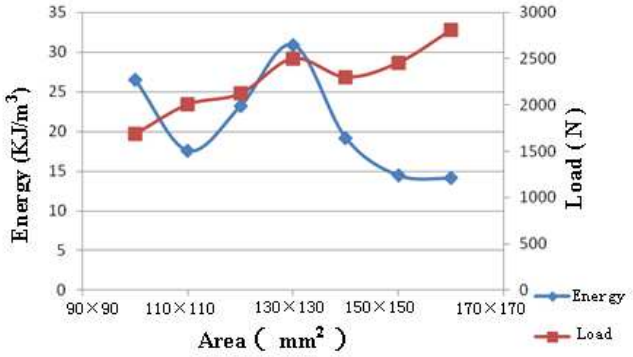

Fig. 2 Energy absorption of unit volume and maximum load curve

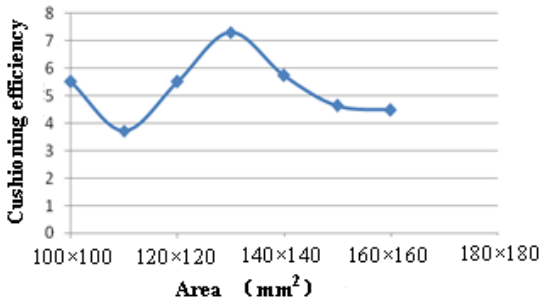

Fig. 3 Cushioning efficiency-area curve

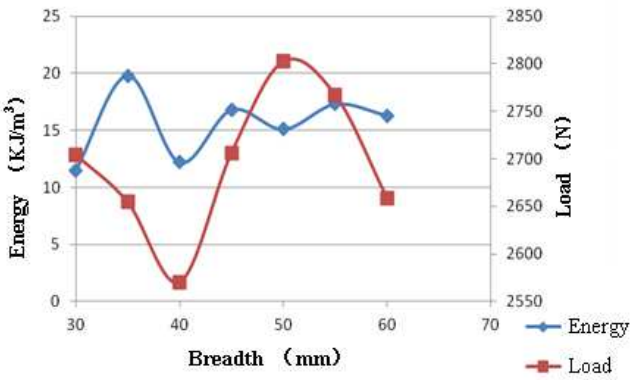

Fig. 4 Energy absorption of unit volume and maximum load curve

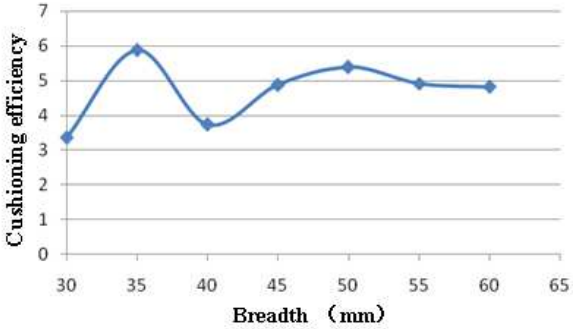

Fig. 5 Cushioning efficiency-breadth curve

Combining table 2 and figure 3, the maximum cushioning efficiency also appears at s=130mm×130mm, namely the cushioning effect is best.

Effect of breadth on the cushioning property. The relationships of breadth and energy absorption of unit volume, and unit volume of energy absorption, cushioning efficiency, maximum compression load are shown in the tables 3.

Table 3 Cushioning parameters under different breadth

Breadth（mm）	30	35	40	45	50	55	60
Load（N）	2704.51	2654.52	2570.08	2706.35	2802.85	2767.33	2658.32
E（KJ/m³）	11.5	19.8	12.2	16.8	15.1	17.3	16.3
ρ	3.36	5.88	3.73	4.88	5.39	4.91	4.82

In order to see the changing trends of maximum load and energy absorption of unit volume following load area visually , the discrete points are fitted. The results is as shown in Fig.4.

With the increase of breadth, energy absorption of unit volume and maximum load have no fixed changing trends, but within the breadth of the experiment, there is an extreme point, which the corresponding breadth is 35mm. Maximum load appears at b=50mm.

The cushioning efficiency of the structure is shown as Fig.5 .

Combining tables 3 and figure 5, the largest cushioning efficiency appears at b=35mm, so the cushioning effect is best.

Summary

In this paper, through the static compression cushion test for 0940 type cushion, came with the increase of load area and side panel breadth, maximum load, the energy absorption of unit volume and cushioning efficiency and best value. Results show that in all tests of the paper, when the load area is 130mm×130mm, side breadth is 35mm, the cushioning efficiency is highest, the cushioning property is best.

Keywords: Children's food, Packaging design, Fun packaging, Food packaging

Abstract. Biscuit, as a common snack, in order to attract the children's attention, besides its taste and shape, packaging design is equally important. The beautifully decorated surface of the box can be divided into a number of blocks (4 or 9) by setting the punch lines. After the biscuits are eaten up, tear the box along the punch lines, then it becomes a simple jigsaw puzzle. Inside the box except the biscuits bag, a cute clamp like scissors added. So the children can gripping biscuits by the clamp rather than by hand directly.

Introduction

Food industry and food market develop rapidly in China. The total output of food industry has risen to the first one in the country. A survey shows that food is the first one in China's urban residents' consumption structure, where children's consumption in the proportion of total household occupying more than 33% in more than 90% of families. The sixth Chinese population census in 2010 shows that the number of children in our country accounts for about 16.60% of the population, We can see children's food market is a considerable market [1].

In recent years, world food consumption grows constantly, and biscuits consumption topped the list in most countries. Although the types of children's food had become more and more, biscuits are always one of most favorite food for kids. Because biscuit can not only satisfy one's hunger, but also can be eaten as a snack. And compared with bread, pastries, biscuit can be stored and carried easier, so it is also liked by the parents [2].

Children are a special consumer group. They are curious and like to explore. Because the children's recognizing of products begin from the overpacks. The colorful pattern and the lively graphics of the overpack can impress children's mind very much. Most of children's biscuits have possessed that basically. Therefore, the entry point of this article is the packaging structure. The aim is to increase interest of the biscuits.

Children's biscuits purchase decision analysis

With the development of market economy and people's changes of consumption, biscuit that is used to allay our hungers or as gift for others before, is moving to leisure, health-based direction. And so are children's biscuits [3]. Children's food market is a special market. Although the target consumer group is children, but parents are the participants during the consumption process, and sometimes parents are the decision-makers. A survey shows children that are under 6 years old, 80% of purchase decisions are made by parents; 70% of children that are 6 years old to 12 years old have the decision-making power. So there are two decision-makers whether or not the product is purchased: children and parents. In consume concept, children and parents are quite different. Children's consumption is a typical emotional consumption, while parents are rational consumption. Whether to buy the biscuit or not, consumers can only determine through the packaging before purchase it. So

packaging is an important factor that attracts their purchase decision. If you want to attract the children's and parents' eyes through packaging, to master their consumer psychology is necessary during the packaging design stage.

Analysis of children's and parents' consumer psychology

Curiosity. Children are curious about everything. Something new and interesting can be a strong temptation for children. Therefore packaging with novel shape, distinctive appearance and full of changes can attract children's attention. Before making purchase decision children judge the biscuit only from packaging styles firstly, and then determine whether to buy it or not. So children's consumer behavior has obvious novelty, odd psychological characteristics, for them the interesting packaging is very important [4].

Fickleness. Children's consumer behavior is purely emotional in nature. They are interested in one thing quickly, and lose interest fast. The unique shape or bright colors of a commodity may attract the attention of children temporarily, but over time will slowly in the cold. Because they find that something else is more interesting. Therefore, in order to keep a kind of biscuit for a long freshness in children's heart the packaging must have sufficient "playable."

Health and safety. When parents are shopping for their children, the first consideration is health and safety. Particularly, food safety issues appeared frequently in modern society, which adds to parents' anxiety while buy food for children. And thus they are more cautious to it. After all, there is only one child per family, it is important than anything else that children grow up healthily. Food safety problems caused by many reasons, in addition to the food itself, the packaging is also the main reason. Even though both of these have no problems, it is bad for children's health while they taking food with unclean hands.

Versatility. For the average family, the children's consumption holds a big proportion of the total household expenditure. If buying one thing can meet children's various needs, which is helpful to reduce the family burden. With the growing awareness of environmental protection, considering the packaging to be versatile at the design stage, and it is popular that do not let them become "disposable" consumables.

So, to be able to attract children's attention, the biscuit packaging had to be novel, rich interesting; to attract the attention of parents, the biscuit packaging must be hygienic and versatile.

Packaging status of children biscuit

Paperboard carton. Now children biscuits mostly chose paper cartons as their sales packaging. And the inner packaging is composite plastics. Because paper materials are more environmentally friendly, recycling convenient and lower production costs, to be printed easier by variety of printing methods and to be decorated by rich colors. Structurally speaking, children biscuit cartons are rectangular mostly, And always decorated by bright colors, cartoon patterns looked lively. This packaging is stronger, and can protect the biscuits well. Once it's squeezed, biscuits will not be crushed easily.

Composite plastic bags. Another big category of children biscuit packaging is composite plastic bags. The characteristics of such packaging are easier processing, lower cost, but weaker protection to the product. Generally, biscuits are crisp, when transported or stored, they are easy broken. Nobody wants to buy a bag of crushed biscuits.

Other packaging forms. There is also a small proportion of children biscuit packaged by metal can or corrugated packaging boxes. Biscuits in metal can are often as gift. This packaging is stronger than others, and can protect the biscuits well. But it is deformed easily while impacted by others. The packaging cost is higher. Corrugated packaging is less cost. But it's more suitable for family pack, and is difficult to attract children's attention.

Interesting packaging design of children biscuits

Biscuit carton design. Packaging is a rapidly growing, high eliminating industry. 70% of packaging output will become waste after single-use. So how to recycle use packaging waste is an extremely meaningful thing.

There are already many food companies are sought to develop multifunctional or recycled biscuit packaging, such as Glico clamshell packaging cartons, Kraft plastic sealed cans biscuits packaging . In order to increase the attractiveness of biscuits and increase the fun of eating biscuits for children, and to avoid the packaging becoming waste immediately after the biscuits were eaten out, children's biscuit carton structure are made the following improvements in this paper. But the decorating style is not changed [5].

Biscuit carton is still the original rectangular structure, and the decoration is also cartoon-based style. On the front side are brand logo, biscuits taste and other information. For the bottom side, cartoon image or beautiful situation that children familiar with are used. And this side can be divided into 4, 6 or 9 pieces with punch lines. According to the increasing ages of the consumer group, the number of pieces can be increased. After the biscuits were eaten out, the packaging carton would become a fun toy – a jigsaw puzzle. The divided bottom side is shown in Fig.1.

Fig.1 The divided bottom side

The benefits of this design are the package's reuse after emptied, and it can also cultivate children's attention and develop their intelligence. The versatile packaging can stimulate the purchase desires of both parents and children. Moreover, these can also be designed as a series of jigsaw puzzles. Children will be curious about collecting all of puzzles, and then they will also enjoy this kind of biscuits.

Biscuit clip design. Now most of the children biscuits require grabbing with hands directly. It is neither hygienic nor interesting, and lack of challenging and fun. It is easy to cause disease if the children just come back outside, do not wash their hands and ate biscuits directly. It is a core objective of children product packaging that making learn more interesting. If we design a lovely "clip" for biscuit, it would be more interesting for eating. Younger children are at the stage of exercise capacity in all aspects. This cute little "clip" not only avoids children's hand contacting with food directly, but also to inspire their desires of learning to grab something with tools. At the same time, their muscles of hands and hand-eye coordination being exercised. So parents will be more confidence when children eating biscuits. In order to attract children, the head of the clip can be designed into a variety of animal heads, for example, bear head. It is shown as Fig.2.

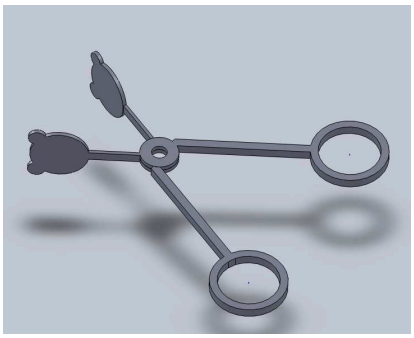

Fig.2 Biscuit clip

Summary

With the social development, the improvement of consumer demand, packaging sustainability is concerned more and more. packaging in line with the requirements of green packaging will be more and more. Child is a special consumer groups. Children's food packaging need constant improving to capture children's interests. Children's food packaging must meet the psychological needs of the consumer group. Besides basic functions, hygiene and interests of packaging are important for children's growth, which is a new challenge presented by age.

Keywords: Coordinate Measurement. Binocular Vision. Axis Calibration of Rotation Stage. Measurement Range

Abstract. For a coordinate measurement system based on binocular vision, system calibration is an important factor for measurement accuracy. In this paper we present a flexible calibration method for the axis calibration of rotation stage which is installed in front of the binocular vision system to increase the system measurement range. By putting a standard ball in front of the binocular vision system, a sequence of pictures is taken by the two cameras with a few different rotation angles of the rotation stage. With the method of space intersection of two straight lines, the reference points(the ball centers at each rotation angles) for axis calibration are figured out. The trail of standard ball is a circle. Since all ball centers of rotation are on a plane perpendicular to the axis, the center of circle is on the axis of rotation stage. The rotation axis of stage is then calibrated according to the calibration model.

Introduction

A basic problem in binocular stereo system is recovering the 3D construction of a world scene or object from a pair of images[1]. The main method to solve the problem is to find a binocular vision calibration method, which has a key effect on the measurement accuracy. To increase the measurement range of the system, a rotation stage is installed in front of the binocular vision system [2, 3], as shown in Fig.1.To reduce effect for the measurement accuracy of the turntable rotation, the rotation axis of stage needs to be calibrated before measurement.

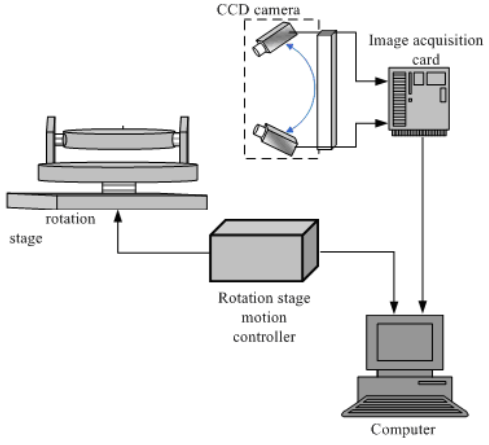

Fig. 1 The system structure

The measurement principle of system

The measurement model is shown in Fig.2[4, 5]. To increase the measurement range of the system, a two-axis rotation stage is installed in front of the binocular vision system.

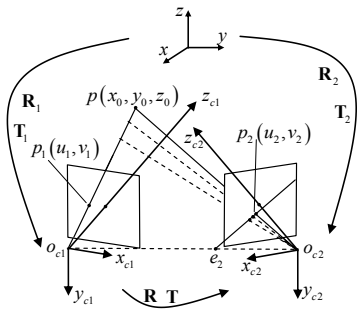

Fig. 2 The measurement model

Since the two axes usually do not intersect at one point, the measurement model should be constructed for this situation as shown in Fig.3: Firstly, the three axes are calibrated using a standard ball with the calibration method. Secondly, $O_{Ay}(x_{Ay}, y_{Ay}, z_{Ay})$ of azimuth axis is set as the origin and the upward direction of azimuth axis is set as the $O_{Ay}Y_{Ay.}$ In this way, the coordinate system Ay is established and the rotation and translation matrix M_{Ay} is determined. Based on the calibration information of pitch axis, two points s_1, s_2 are obtained and these two points can be converted into the representation in the coordinate system Ay. The rotation and translation matrix of pitch axis is M_{Ax}. Finally, given rotation matrix R (x) and R (y) which donate a object rotate around a fixed axis, the measurement model is built as shown in formula (1) according to the rotation order: azimuth (rotation angle a)→pitch (rotation angle b).

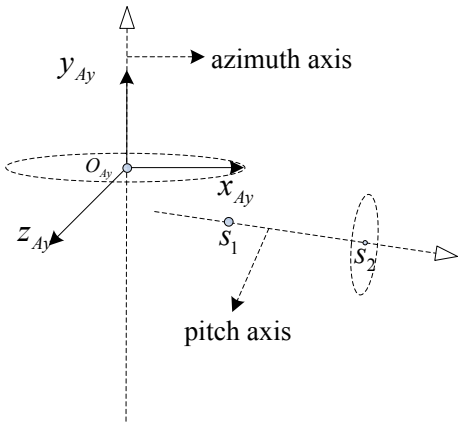

Fig. 3 The measurement model of two-axis rotation stage

$$\begin{bmatrix} \cos a & 0 & \sin a & 0 \\ 0 & 1 & 0 & 0 \\ -\sin a & 0 & \cos a & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \mathrm{M}_{\mathrm{Ax}}(b)\mathrm{M}_{\mathrm{Ay}} \begin{bmatrix} x_{wi}^1 \\ y_{wi}^1 \\ z_{wi}^1 \\ 1 \end{bmatrix}^T = \mathrm{M}_{\mathrm{Ay}} \begin{bmatrix} x_{wi}^2 \\ y_{wi}^2 \\ z_{wi}^2 \\ 1 \end{bmatrix}^T \tag{1}$$

The calibration method of rotation stage axis

The basic principle of rotation axis calibration is to locate a line which represents the rotation axis and this line is donated by a vector and a point on the line.

In the process of calibration, after the images of a standard ball are acquired by the two cameras with different rotation angles of stage, the calibration of rotation axis is carried out. With the binocular vision system calibrated, the world coordinate of the standard ball center at each rotated position can be worked out considering the intersection of the ball center projecting line in the two cameras respectively. Because of the rotation of the stage, the trail of the ball center is a circle, whose center is on the rotation axis. All ball centers rotated are on a plane perpendicular to the axis.

The rotation axis of stage is expressed with a point on the axis and its vector. The calibration process is shown in Fig.4:

1) Rotate the stage and the coordinates of standard ball center in N positions are measured. So N groups of standard ball centers′ coordinates $O_n(x_n, y_n, z_n)$ are obtained.

2) Using the N groups of standard ball centers′ coordinates obtained in step 1, the least squares method is used to fit a plane. The plane can be considered as the rotation trail of ball center and the normal vector of the plane is the direction vector of the rotation axis, as shown in formula (2).

$$\begin{cases} A x_n + B y_n + C z_n + D = 0 \quad (n = 1, \cdots) \\ \mathbf{u} = [r_1 \quad r_2 \quad r_3]^{\Gamma} = \left[\dfrac{A}{\sqrt{A^2 + B^2 + C^2}} \quad \dfrac{B}{\sqrt{A^2 + B^2 + C^2}} \quad \dfrac{C}{\sqrt{A^2 + B^2 + C^2}} \right]^{\Gamma} \end{cases} \tag{2}$$

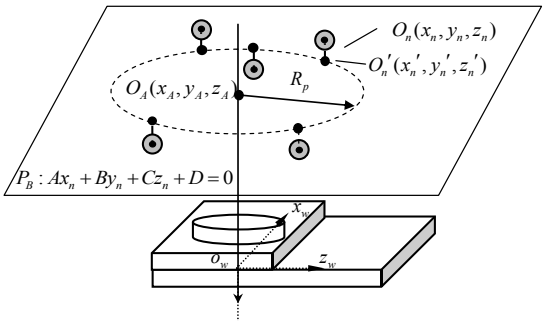

Fig. 4 The calibration of rotation axis

3) The N groups of standard ball centers′ coordinates $O_n(x_n, y_n, z_n)$ obtained in step 1 are projected to the plane obtained in step 2 and N groups of corresponding projection coordinates $O_n'(x_n', y_n', z_n')$ are obtained. The point that has the minimum distance to these projection points is searched in the trail plane by the objective function in formula (3). In this way, the point $O_A(x_A, y_A, z_A)$ is obtained which is the intersection point of the rotation axis and the trail plane of ball centers.

$$f(x_n', y_n', z_n') = \sum_{i=1}^{N} \left(\sqrt{(x_n' - x_A)^2 + (y_n' - y_A)^2 + (z_n' - z_A)^2} - R_p \right) = \min \tag{3}$$

Experiment Results

The following method is used to verify the accuracy of rotation calibration: the standard ball is placed on the two-axis rotation stage. The coordinates of ball centers are measured in 12 different locations through the rotation of stage and the mean value of coordinates are calculated according to formula (4).

$$\bar{x} = \frac{\sum_{i=1}^{12} x_i}{12}, \bar{y} = \frac{\sum_{i=1}^{12} y_i}{12}, \bar{z} = \frac{\sum_{i=1}^{12} z_i}{12} \tag{4}$$

The error of measurement results is calculated according to formula (5).

$$e_i = \sqrt{(x_i - \bar{x})^2 + (y_i - \bar{y})^2 + (z_i - \bar{z})^2} \tag{5}$$

The RMS of measurement results is finally calculated and is shown in table 1.

Conclusion

In summary, this paper presents a flexible calibration method for binocular stereo vision. A new calibration pattern with four big circles is designed, whose spatial coordinates system is built by the position of the four big circles. With several views of the plane pattern in different orientations, the parameters of the binocular stereo vision system, including the intrinsic parameters of each camera as well as the relative position translation matrix of two cameras, is calibrated using Zhang

plane-based calibration algorithm. The exterior orientation of the turntable axis is figured out by a sequence of images of a standard ball with different rotating angles. In the experiment, the diameter of a column bearing, whose diameter is 50.181mm measured by CMM, is measured using the calibrated binocular stereo vision system. With the least square method, the precision of the final measurement result is better than 0.025mm.

Table 1 Experiment results

Serial	Angle	Error(mm)	RMS
1	0°	0.066	0.0236mm

Keywords: Cantilever. Low consumption. Flow meter

Abstract. In order to reduce consumption of thermal flow meter and prolong its working life, this article makes a research on cantilever switch, which control the circuit and save its energy. A cantilever was added into flow meter and was put into the air flow aisle in front of sensors. Process was designed and nano-imprint method was used to realize cantilever. The device was simulated and the effect on reducing consumption was certified, which has great significance on thermal flow meter.

Introduction

MEMS (Micro Electro Mechanical Systems) thermal mass flow meter response quickly, has large detection range, has perfect sensitivity and good stability for low flow, with excellent applicability in industrial and civil. However, the device has energy problems due to the use of DC battery power, and the circuit needs to be designed to improve energy efficiency. It is a good way to decrease power consumption by turning off the circuit when no gas passes through, but when the gas passes again, we need to open the circuit.

Under these circumstances, this article designed a kind of switch by use of cantilever. There are so many other applications in fluid measurement about cantilever, most of which take advantage of its dynamic characteristics to readout the velocity of flow, there are many restrictions and high demands on the circuits. In this paper, the static characteristic of the cantilever was used to open the circuit when gas flowed, and then the flow meter worked to read the flow rate and cumulate the count. The circuit switched off when there is no airflow, which greatly reduces power consumption, and the complexity of circuit.

Technical principle

Structure of cantilever was shown in Fig.1, there are two state positions about the cantilever, the position 1 of the cantilever in a stress-free state, and the position 2 of the cantilever was deformed to connect the lower electrode by external pressure.

When the cantilever is affected by a uniform distribution of stress q, we can get the deflection ω [1]:

$$\omega(x)=(x^2-4Lx+6L^2)qx^2/24EI \quad (1)$$

X is the distance from measured point to the fixed point, L is the length of the cantilever, E is Young's modulus, I is the moment of inertia.

If X = L, the maximum deflection of the cantilever end is:

$$\omega(L)= qx2/8EI \quad (2)$$

Fig.2 show us the structure of flow meter in aisle, from which we can find the switch is consists of two parts, metal cantilever and metal contacts. Put the cantilever in the aisle whose bending direction is parallel to the gas flow channel. Pressure of flow passed will make the cantilever bending downward to touch the metal contacts, then the circuit turns on, and switch is in "ON" state; if no ambient fluid, the cantilever will restored to initial state, the circuit is disconnected, then the switch is in "OFF "state. In "ON" state, the switch insertion loss is mainly determined by cantilever resistance and contact resistance; in "OFF" state, the main switch isolation is determined by the capacitor

between cantilever and micro strip line. From Fig.2 we can found, the switch structure can be equivalent to a micro strip gap in series of a cantilever, which can illuminate its equivalent circuit.

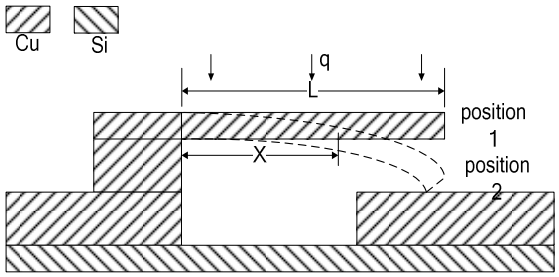

Fig.1 Mold of cantilever changed with force

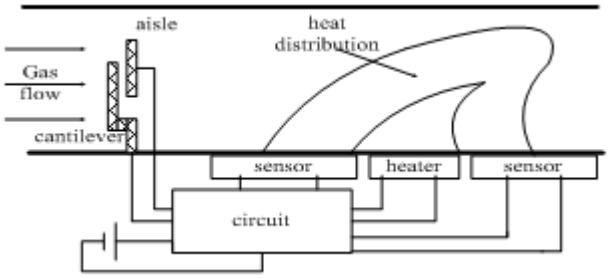

Fig.2 Structure of flow meter in aisle

Process of Cantilever

Nano imprint technology subject to top-down manufacturing technology, and has great advantages of simple operation, high resolution, low cost and high production efficiency. It can be used in high repetitive manufacturing of micro/nano graphical structure, which can decrease cost and process compare to lithography [2-3]. We designed the cantilever by use of nano-imprint technology combined with microelectronics process, and the specific process is shown as follows (Fig.3):

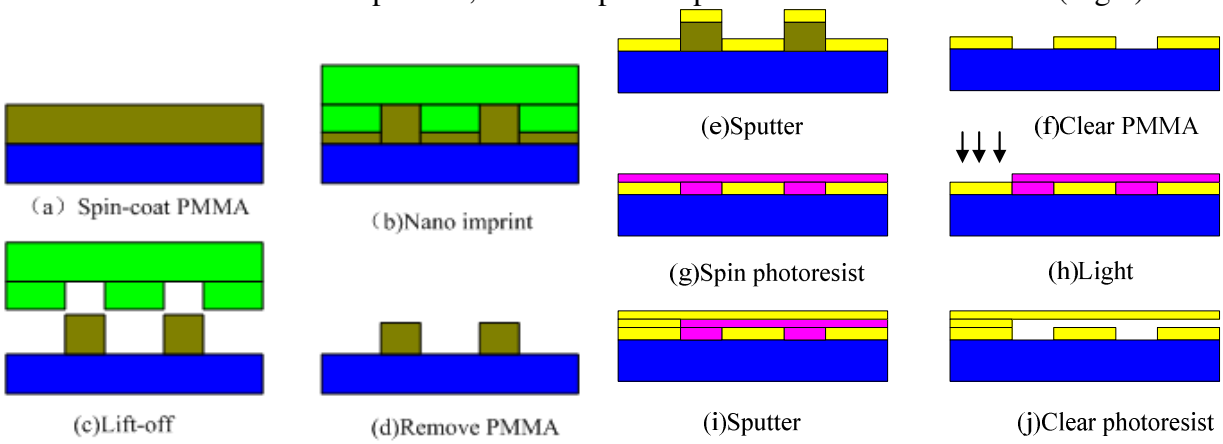

Fig.3 Process of MEMS switch

Preparation of cantilever is the key of our design. The bottom layer of cantilever in this article is Silicon, mainly plays a role of insulation and supporting; the middle layer and the top layer are metal, which consist of the cantilever switch. There are two key factors which can influence the cantilever: lithography and temperature. Lithography determines the graph of cantilever, and temperature is another important factor, the sacrificial layer here is photo resist, which is difficult to be removed if temperature upper to 120 ℃ in whole process [4-6].

Simulations

Using IntelliSuite software, we modeled and simulated the cantilever beam. Impose simulation conditions on the device, and add airflow onto cantilever, then the micro-cantilever deformed and connected to metal contacts, the circuit turned on. Cantilever in the gas path is perpendicular to the channel, and gravity can be ignored.

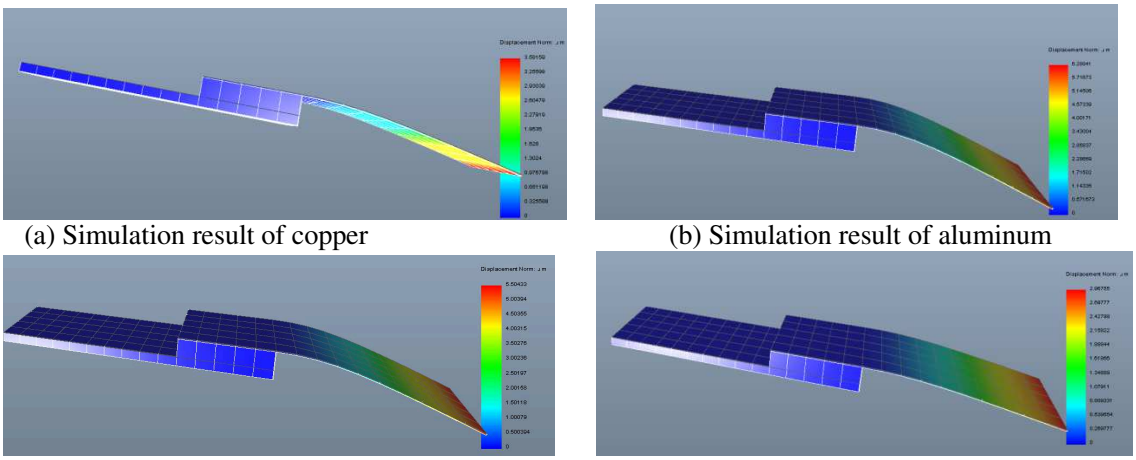
Applying pressure onto the upper surface of the cantilever, the beam will bend downward. There are many different results by changing the material of metal layer at same conditions as Fig.4, the material parameters are shown in Table 1. Thickness of cantilever is 0.1μm, length is 20μm, and width is 10μm.Simulation pressure is 2e-3 Mpa.

The simulation results is shown in Fig.4, we can found the degree of bending is different for each material under same conditions, copper material is deformed about 3.58μm, the aluminum material is about 6.29μm, aurum material is about 5.5μm, and platinum material is about 2.97μm. By analysis of

the results, we found the Young's modulus of the material is closely related to the curvature. To verify this idea, a series of simulations were done by only changing Young's modulus on copper. The simulation result of different young's modulus shown in Table 2 below.

Table 1 Setting and result of simulation

material/parameter	Young's modulus（GPa）	Poisson ratio	density(g/cm3)	deformation（μm）
copper	122.5	0.34	8.9	3.58
aluminum	68.85	0.36	2.7	6.29
aurum	74.48	0.42	19.28	5.50
platinum	146.9	0.35	21.45	2.96



(a) Simulation result of copper (b) Simulation result of aluminum

(c) Simulation result of aurum (d) Simulation result of platinum

Fig.4 Result of simulation for materials

Table2 Simulation result of different young's modulus

Young's modulus (Gpa)	122.5	100	80	68.85
Bending displacement(μm)	3.58	4.39	5.48	6.29

The result tells us, bending degree of the device is increased with the decline of Young's modulus. When the Young's modulus decreases to the size of aluminum, the bending displacement is the same of aluminum. Then the results can be drawn, bending degree of one structure is only correlated with Young's modulus, and bending degree is inversely proportional to the Young's modulus of material.

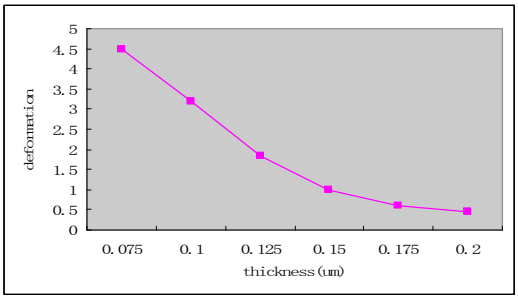


Fig.5 (a) influence of thickness

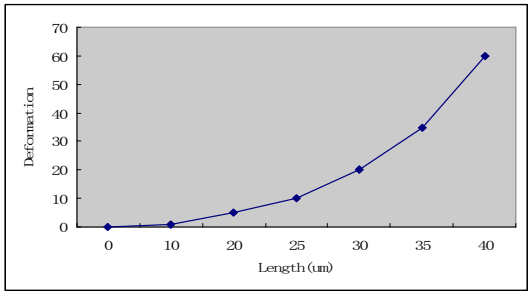

Fig.5 (b) influence of length

Fig.5 shows the effect of the Cantilever size. In Fig.5a, with the increases of cantilever thickness the bending is exponentially decline. Fig.5b shows the effect of the length of cantilever. It can be seen that bending of cantilever is exponentially increased with the increasing length. Thus shows that cantilever scales have a decisive impact on switch. Fig.6 shows the examples of curved cantilevers which is deformed under same condition.

Experiments

MEMS process was used to fabricate switch, combined with nano-imprint lithography process. PMMA was used as imprint glue, and Cu film was sputtered as electrode after making proper

graphics. By using photolithography technique, the sacrificial layer is made of photo resist. Then Cu film was used to make the cantilever. We also found that, with the increase thickness of Cu film, there are many holes on the film, which indicate that there is large stress of Cu film deposited. So the thickness of cantilever should be considered, we chose 2μm in this article, and Fig.6 is the picture of cantilevers.

From the test result of our experiment, the switch can work in the isle, but there are also some other problems need to be solved in next work.

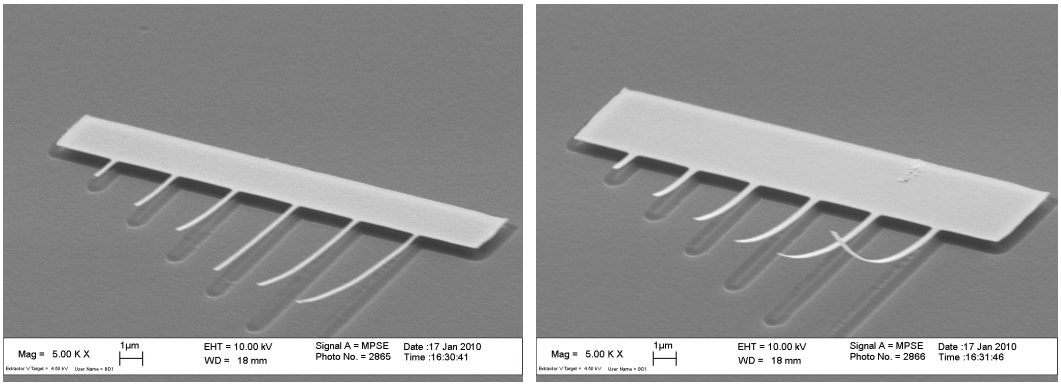

Fig.6 Deformation of cantilevers

Summary

From the simulations of the device in terms of pressure, this article verified the cantilever deflection is inversely proportional to Young's modulus. By adjusting the film thickness and length, we can find the curvature of the cantilever is different, degree of bending is proportional to the length, and inversely proportional to the thickness. But a quite long cantilever has a poor resistance to fatigue, so the size of cantilever should be determined by actual.

The usage time of gas is far below its idle time, put the Cantilever switch into a fluid channel can greatly reduce power consumption and save energy.

Keywords: ADS1282;FPGA.Multichannel. Marine seismic exploration

Abstract. For marine seismic data acquisition needs,a multichannel marine seismic data acquisition unit was designed,which used the 32-bit analog-to-digital ADS1282 as a core and Field programmable gate array(FPGA) as the acquisition controller.The unit can achieve multichannel seismic data sampling and transmission functions.The design fully used with the design ADS1282 chip integration,with the corresponding anti-jamming measures,not only simplified the circuit design,but also ensured the quality of signal acquisition and system stability.the design used FPGA to realize a multichannel hydrophone signal synchronization sampling.

Introduction

Data Acquisition Systems Acquisition in signal quality depends largely on the analog-to-digital converter and Application.To meet the high accuracy and multichannel requirements of Marine seismic data acquisition, this paper design a high level of integration of multichannel seismic data acquisition system,it can achieve 12 channel marine seismic signal acquisition and data transfer capability.Using the new-style analog-to-digital converter ADS1282 to realize the data conversion, it is not only could obtain high fidelity, high-resolution data signal, but also could use gain and offset calibration registers to realize self-test and system calibration. So it is assured the sampling data quality won't be changed with the time,location,environment and condition.Using FPGA as controller of the system,can achieve a multichannels data synchronous acquisition and transmission.The unit has a low-power,small-footprint, high-precision and high-resolution features. It is very suitable for high precision marine seismic exploration area.

Introduction of ADS1282

The ADS1282 provided by Texas instrument company is an extremely high-performance, delta-sigma($\Delta\sum$) analog-to-digital converter(ADC).The converter provides 24-bit or 32-bit output data in data rates from 250SPS to 4000SPS. It is composed of multiplexer,programmable gain amplifier,delta-sigma ($\Delta\sum$) modulator,gain and offset calibration register,over-range detection circuit, control logic,SPI serial interface and so on.The ADS1282 is available in a compact TSSOP-28 package and is fully specified from –40°C to +85°C, with a maximum operating range to +125. It is well applied in industry fields such as energy exploration, seismic monitoring and other exacting applications. The ADS1282 has following features[1].

Data Acquisition System Design

System composition. Multichannel marine seismic data acquisition unit design is based on a distributed design philosophy of marine seismic data acquisition system,the data acquisition unit can achieve multiple channel marine seismic data acquisition and data transmission capabilities, can effectively remove the interference signal in the analog signal transmission, improving the quality of seismic signal acquisition, seismic signal processing and waveform display and logging features, done by a control host.

Multichannel seismic data acquisition hardware is mainly composed of piezoelectric hydrophone, A/D converters, FPGA, power supply management module and transmission interface.For

low-power, small-footprint design purposes using the FPGA realization data gathering and the data multiple transmission. For high precision and high resolution,analog to digital conversion using the ADS1282.Distributed marine seismic exploration data acquisition system for each collection interval up to 300 meters, the system dedicated transfer chips for high-speed data in long-distance transport.Fig.1 is the block diagram of data acquisition unit.

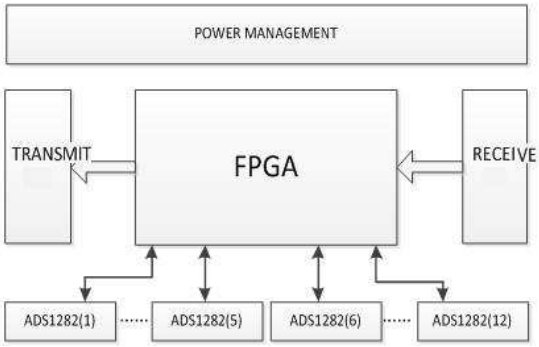

Fig. 1 Hardware Compose of Digital Geophone

Interface of Hydrophone with ADS1282.The data acquisition unit is mainly used for marine seismic exploration , the sensor(hydrophone) gets a seismic wave signals are converted to digital signals and then pass through the transport interface to control host. In order to enhance the quality of sampling signal and effectively reduce noise created by environment, the output signal of hydrophone is sent to analog inputs of ads1282 through front-end filter network with differential mode.

Fig.2 is the interface circuit of hydrophone and ADS1282.In this application,ADS1282 is provided by ±2.5 V power.High-frequency normal mode components from the input signal is removed by the filter network which consists of R1, R2 and C1,C2,C3.To maintain good common-mode performance, R1,R2 should be matched to 0.1%. Capacitor C3 in parallel with C1 can effectively reduce the common-mode errors caused by C1,C2 not matching. If C3 is 10 times larger than C1, the common-mode error will be reduced 20 times[2].

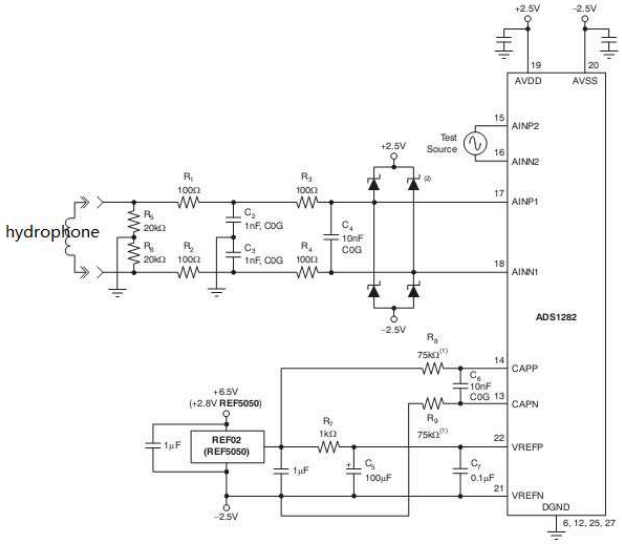

Fig. 2 Hydrophone Interface Application

Clamping diodes are used to protect the ADS1282 inputs from voltage overloads. REF5025 provide the voltage reference for the ADS1282.The output of filter through R5, C7,C8 provide high frequency bypass for input signals reference.C8 should be placed close to pins of the ADS1282.R3,R4 and internal resistance form the divider voltage circuit to provide offset voltage for the ADS1282.The offset can remove low level useless tones from pass-band. To maintain good common mode rejection, R3 and R4 should be matched to 0.1%[1,2].

Interface of ADS1282 with FPGA. ADS1282 accessed through the serial interface to read data and set register,ADS1282 provide 32-bit binary complement format data.The serial interface is 3-wire SPI interface,which includes three basic signals:SCLK,DIN and DOUT.ADS1282 also has synchronized signal, clock signal, reset signal.When converting data ready for reading, DRDY signal can be used to mark the judgment, when it changes into a low level indicates a new conversion data is prepared,the data will be captured at the next rising edge of SCLK by FPGA.

Total of 12 channels ADS1282 in the acquisition unit,they take parallel connection mode, and 12 channel ADS1282 with a CLK,SCLK ,DRDY and reset signals.each ads1282 has a DOUT signal and DIN signal connect with FPGA,so that ensures all ADS1282 synchronization of acquisition[3,4].Fig.3 is the data transmission and control interface of ADS1282 with FPGA.

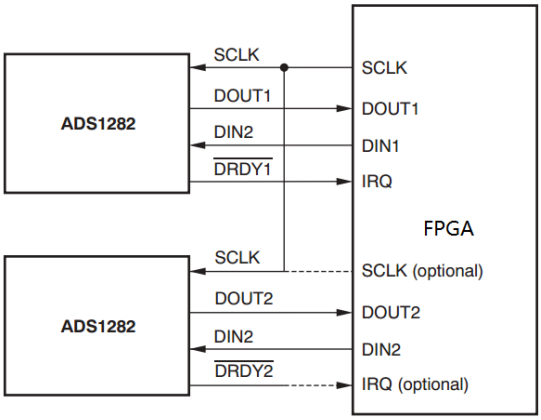

Fig. 3 Interface of ADS1282 with FPGA

Experiment

According to national standards for marine seismic data acquisition system,We tested the performance of acquisition unit,include equivalent input noise,Harmonic distortion,Common Mode Rejection Ratio and Channel crosstalk[4,5].In the sampling frequency is 1000SPS, the preamplifier gain of 0dB,the input signal frequency is 31.25, scope is 2V test condition, carries on 5 tests respectively to 10 gathering units, finally averages the value.the result of compare test results with national standards is shown in table 1.From the test results show that this acquisition unit to meet national standards A-index of petroleum seismic data acquisition system requirements.

Table 1 The compare of test results with national standards

Test Items	Test Results	National Standard
Equivalent input noise level	1.26	≤1.6uV
Harmonic distortion	0.00021%	≤0.0005%
Common mode rejection ratio	113dB	≥90dB
crosstalk	118dB	≥100dB

Summary

Take ADS1282 as the A/D chip,FPGA as the controller is a new pathway of multichannel marine seismic exploration acquisition unit,it simplifying the circuit design,reduces power consumption while increasing the stability of the system,is ideal for high-accuracy data acquisition system.The acquisition unit has been applied to distributed marine seismic data acquisition systems,performance is good.The sampling unit can also apply to other situations that require high-accuracy data acquisition,has broad application prospects.

Keywords: Weak signal extraction. Multi information fusion. Hybrid intelligent diagnosis. Embedded online monitoring unit

Abstract. As an important mean to ensure machining accuracy, the dynamic measurement and intelligent fault diagnosis technology can be used in aviation manufacturing machine. In recent years, several theoretical results are gotten on weak signal feature extraction, multiple sensor information fusion of early fault identification as well as the set up of embedded online monitoring units. This article is the summary of those results, the existing problems is analyzed, and the trend of the development in this field is also discussed.

Introduction

As the requirements of improving machining quality in advanced manufacturing technology, the technology innovation and breakthroughs of high-end multi-axis NC machine represented by high speed, high precision have the important significance and engineering application value. Because of the complexity structure, many factors lead to poor machining quality, if the error sources can not timely and accurate diagnosis, the machining quality and accuracy will not be able to guarantee and even cause other major losses such as machine scrap. It is necessary to study dynamic monitoring and intelligent diagnosis technology, especially in abnormal processing state recognition and intelligent maintenance theory, the dynamic measurement and intelligent diagnosis software is also need to develop in order to display machining state, diagnose fault and predict performance [1-5].

Analysis of the current situation and trend of development

The fault of high-end CNC machine tools includes electrical fault and mechanical fault. the electrical system fault can be diagnosed by means of NC system self-check such as drive current, Angle, torque motor, etc. The commercial monitoring system, such as Siemens EPS and FANUC 18I series monitoring system have already developed. Although single functional monitoring and diagnosis system is developed, such as Kistler cutting force monitoring system and ARTIS tool monitoring system, those monitoring systems mentioned above can diagnosis specific fault based on monitoring information. But according to the characteristics of high signal-to-noise ratio and complexity signal modulation of fault signal, further study in early failure of weak signal detection and fault signal extraction technology is still need to research. The effective hybrid intelligent fault diagnosis model should be set up to improve the accuracy of fault prediction.

The manufacturing quality in precision machining is easily influenced by the CNC equipment organic fault. Fault once appear, will immediately change the machining accuracy. However, the early fault characteristic signal, such as the amplitude of vibration, current, acoustic emission is relatively small, further more, by the influence of noise, data acquisition device noise, signal transmission coupled noise, signal to noise ratio often low. The primary task of weak signal noise monitoring and feature extraction is signal noise reduction, which requires the use of electronics, information theory, computer and physics methods. According to the statistical characteristics of the measured signal and noise and their differences, find useful signal from the background noise. In addition, due to the rapid and real-time needs in fault diagnosis, the data length often limited. Therefore, the development of the weak signal detection technology should be attributed to two

aspects: one is to improve the detection capability, reduce the noise of the signal and get an accessible signal to noise ratio; another is to improve the detection speed, meet the real-time monitoring and diagnosis requirements.

At present, the main methods of weak signal detecting is in time domain and frequency domain, the time domain method including sampling integral, digital average, correlation detection, adaptive noise cancellation, frequency domain method including FFT, power spectrum density, filter etc.. However, for short data point, low signal to noise ratio, when the noise frequency and signal frequency is close or coincident, the weak signal detection method has some defects, such as short data lead to low resolution when the FFT is used, the noise can not be average out. When the noise is suppressed, the useful signal is also filtered. These problems affected the common detection methods mentioned above. In recent years, some new methods of weak signal detection is studied, such as: differential oscillator, wavelet transform, cyclic statistics theory and high order statistics, independent component analysis, empirical mode decomposition, stochastic resonance and integrated applications of various methods.

Due to the one sensor can only get signal information, for the complex information of CNC machine fault, a variety of sensors should be acquired to get different information. Multi sensor information fusion is a multi information detection system from the aspects of various sensors and the integrated use of their respective advantages, to achieve accurate, timely operation condition judgment of mechanical system. In this method, the multi sensor information fusion system can effectively use the sensor resources. Compared with the single sensor system, the prominent advantage of multi-sensor information fusion is that information redundancy, fault tolerance, complementary, real-time and low cost.

The machine features are always complex, as the multi signal modulation and the diversity characteristics of monitoring signal, dynamic monitoring and intelligent diagnosis of machine has such characteristics like : a large amount of signal should be measured, the variability of diagnostic process, randomness, fuzziness and other issues, a single fault diagnosis method is difficult to make accurate prediction. Therefore, using the method of multi information fusion and intelligent hybrid fault diagnosis strategy is the development trend of intelligent fault identification.

In recent years, researchers use the fault diagnosis expert system, fuzzy theory, neural networks, evolutionary algorithm analysis, and artificial intelligence methods in NC machine fault diagnosis. Neural network is widely adopted method applied in recent years. But this method has some problems such as diagnosis information is not complete, lack of training samples. There are some other methods like expert system structure based on Web, radial basis function neural network, intelligent diagnosis model empirical mode decomposition and least square support vector machine.

The setup of CNC machine dynamic monitoring platform

The ultimate goal for theoretical study on dynamic monitoring and intelligent diagnosis technology is to build these algorithms in NC machine online detection platform, real-time detect and diagnose machining operation state. From the existing online detection equipment, due to volume constraints lead to complexity of installation, and special embedded monitoring module always has a long development cycle, it is difficult to adapt to the development needs of open architecture and function module of reconfigurable CNC system. The following describes the construction method of online detection unit modular with reconfigurable features, this online monitoring framework include network technology, database technology and artificial intelligence technology, which is on behalf of the dynamic monitoring and intelligent diagnosis's direction of NC machine.

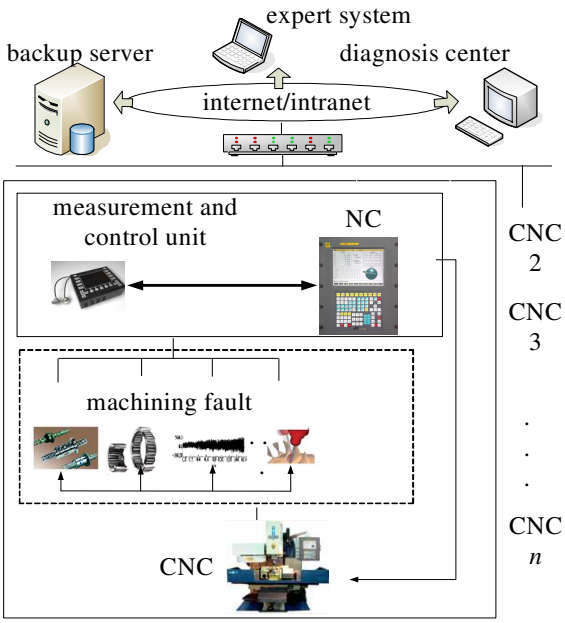

Fig. 1 Integrated monitoring embedded measurement unit on the open architecture CNC system

Fig.1 shows integrated monitoring embedded measurement unit on the open architecture CNC system, this embedded measurement unit has the independent central processor to ensure the real time implementation of NC instructions and online monitoring function. Construction of online monitoring unit includes PC104 PLUS architecture bus, signal conditioning module, the data acquisition card, XPE embedded operating system installed in the CF card and online monitoring software.

The monitoring data acquired by embedded condition monitoring unit can be upload and fault diagnosis code in remote monitoring system can be download by internet when those information has not real time requirement. The network structure use hybrid architecture of C/S and B/S structures, the system provides a variety of commonly used network database options (such as Sql Server, Oracle), the whole system can be divided into three layer network, including C/ S model of fault monitoring system and B/S model equipment management information network, and finally constructs in ERP system in the enterprise.

Data transmission protocol of fault information is used by the information description method of "factory - monitoring unit - point - monitoring quantity". The data transmission protocol mainly includes the following 4 parts: (1) The initial data segment: including initial identification monitoring data, monitoring, monitoring time and date. (2) Monitoring global data section: provide status acquisition parameter setting information, such as the parameter analysis of frequency, gain, sampling points, the total channel number, channel settings. (3) Monitoring data: the machine monitoring signal, waveform information. (4) End of data identification segment: including the identification of the data packet end.

Summary and Prospect

Several methods have used in complex manufacturing system fault diagnosis, such as multi sensor information fusion, hybrid intelligent fault diagnosis modeling and on line monitoring platform for weak signal. But it should be noted that, dynamic monitoring and intelligent diagnosis are still false forecast, especially for real time intelligent control needed further studies. Carry out the study of dynamic monitoring and intelligent diagnosis theory and engineering application is important to the promotion of Chinese industry level of manufacturing, which has important significance and engineering application value.

Keywords: Offshore drilling platform cleaning robot. Communication module. Multi-sensor. Control strategy

Abstract. Communication module design is one of the key technologies in offshore drilling platform cleaning robot, through overall design and analysis of communication systems, the communication module is selected and technology roadmap is analyzed. thus communication module hardware architecture (PC, PLC and multi-sensor) is designed, multi-sensor (Sonar, infrared, camera, SINS, pressure sensors and fiber optic gyrocompass) underwater monitor is designed and selected, the system software is programmed (PC configuration software, PLC software and communication protocol software); Finally, control structure and running track is designed. The research ensures the operation accurately and improves the cleaning efficiency.

Introduction

Offshore drilling platform is the structure used for drilling, the research of attachments cleaning robot for offshore drilling platform is used for replacing manual operation, and get high efficiency and safety work environment for attachments cleaning[1]. Because of the complexity of the underwater environment, offshore drilling platform cleaning robot is operated under the complicated condition, such as deep water depth[2], water quality turbidity, currents and other restrictions, thus, the communication module should be designed to ensure accurate delivery of operating instructions to robots, and meanwhile, the real-time state should be feedback to the operators and improve the cleaning efficiency[3-4].

In view of the above problems, the communication module of offshore drilling platform cleaning robot is studied. Based on the overall design and analysis, each communication system module is selected and research technical route is designed. the communication module (include PC, PLC and sensors) hardware structure is designed, multi sensors (include sonar, infrared, camera, inertial navigation, optical fiber and the pressure sensor) is selected, under water monitoring software is programmed (include PLC software and communication protocol, the PC configuration software); Finally , the cleaning robot mechanical structure and control method is studied. The research ensure the operation precision of the offshore drilling platform cleaning robot, and improve the cleaning efficiency[5].

The general design of communication module

The hardware of offshore drilling platform cleaning robot communication module is mainly composed of PC, console, display, PLC and sensor module. The main content of communication is to control the monitoring data of underwater upload and control date download. The overall design structure diagram is shown in Figure 1.

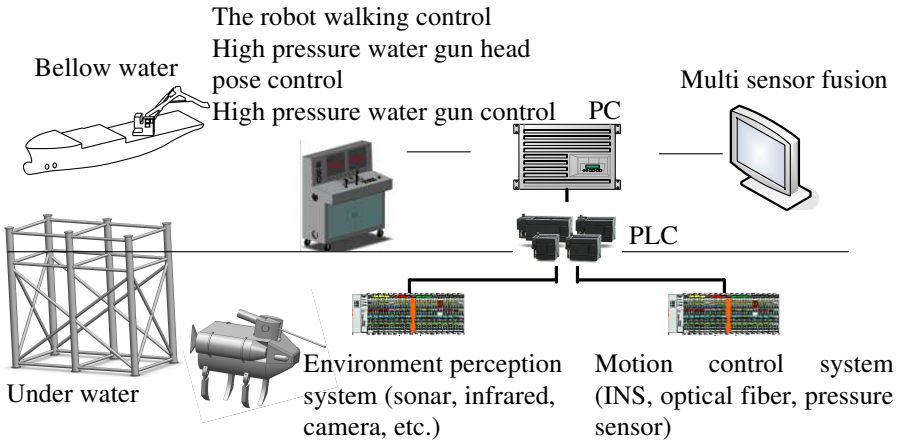

Fig. 1 The overall design of communication module structure diagram

In Figure 1, the control data transmission refers to the robot operator using the ship console, PC and display system sending instructions to PLC, after switching input, output, analog input, output module, the logic arithmetic, A/D, D/A conversion as well as the input signal, feedback signal processing, electromagnetic valve, motor actuators is under control. The upload of underwater monitoring data refers to all types of sensors of the robot with access to the underwater environment and cleaning state data, via PLC upload to the computer, and the software can display it real-time.

The hardware structure design of communication module

The communication between host computer and PLC as shown in Figure 2, the computer is composed of industrial control computer, host computer mainly process two part of the data, the data receiving and display. The Siemens S7－200 is selected. The communication between PC and PLC use PC/PPI cable to implementation and communication.

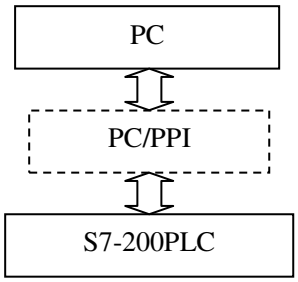

Fig. 2 The communication between host computer and PLC

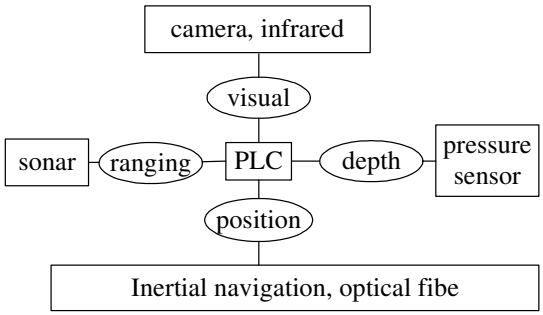

Fig. 3 Multi sensor information flow chart

PPI communication protocol, the computer and PLC chose master-slave mode of communication interface, the master equipment is the computer, slave equipment is PLC. In the process of communication, computer and PLC send handshake protocol to make and receive signal instructions. The PLC instructions signal is received and checked, if without any error, PLC will feedback checked and correct information to the computer, after the computer receives the feedback signal, the confirm order is send back to the PLC and began to implement the operation response.

The multi-sensor structure design of Communication module

The multi-sensor system of offshore drilling platform cleaning robot include environmental perception system module (sonar, infrared, camera) and the movement control system module (inertial navigation, optical fiber gyro, pressure sensor), inertial navigation and optical fiber gyro,

which are used for positioning the cleaning robot when offshore drilling and production platform diving operations; The camera and the infrared sensor is used to read the image of the seafloor environment, sonar is used for measure the distance between offshore drilling platform cleaning robot and the jacket; Pressure sensor used in cleaning robot to obtain depth information. The multi-sensor information flow chart is shown in figure 3.

In communication design of multi sensors, the core idea is the multi sensor information fusion technology, establishes the integrated navigation system based on multi sensor fusion technology (a combination of strap down inertial navigation system, pressure sensor, optical fiber compass). Take strap down inertial technique as the main navigation system, optical fiber and pressure sensor as the aided navigation system, compensation and correction of the error of strap down system. The final construction of navigation system model shown in Figure 4, achieve multi-sensor fusion integrated navigation and ultimately achieve control of posture and movement.

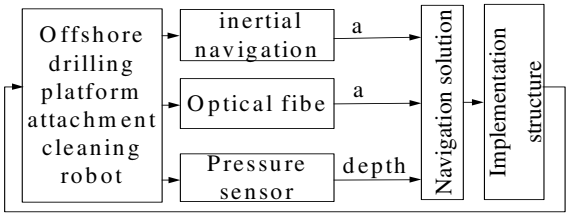

Fig. 4 Multi-sensor integrated navigation model

Fig. 5 PC monitor screen

The structure design of communication module software

The communications of pressure sensor information go through PLC EM231 analog expansion module and converted to digital signals to PLC. PLC EM231 analog input port is AIW0, Pressure sensor range choose 0~16MPa, current range 0~20mA, in the internal of S7-200 CPU, 0~20mA corresponding to the numerical range 0~32000. So that the sea level pressure is 0.1MPa, Seawater depth 0~1000 meter corresponds to0.1MPa~16MPa. The program can get based on the principle of the above analysis,

As shown in Figure 5, the PC monitor screen can display real-time propeller work, depth information and video surveillance footage, the software can also control the related operation of cleaning robot in the other interface.

The control strategy design of communication module

From the first step when robot work, the work path optimization should not only makes the cleaning efficiency, but also reduces the probability of unnecessary fault. Robot motion path is shown in figure 6. At the appropriate position of the cleaned water institutions(tower), the start point is seledted, Then design an unrepeated pathway until back to the starting point .The advantages of this path design is difficulty homogeneity robot task, no duplication of work and the total workload can be optimized.

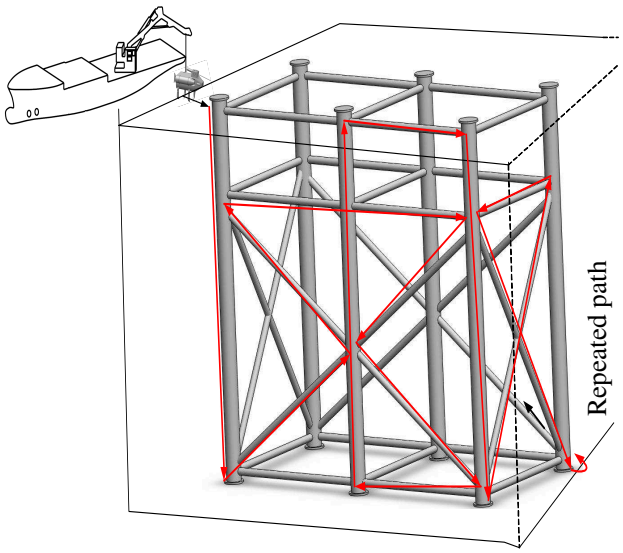

Fig. 6 The robot path planning under water

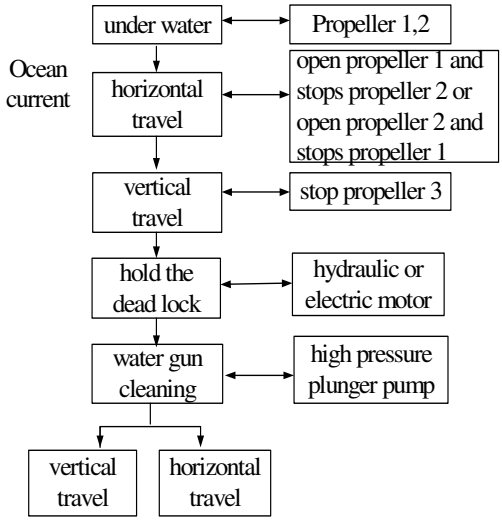

Fig. 7 Mechanical control flow chart

Figure 7 shows the mechanical control flow chart reference figure 6. When the robot into the water, the first step is float to dive location, to maintain balance in the water, propeller 1 and 2 on the back of robot should be opened at the same time, considering the current factors, the method such as open propeller 1 and stops propeller 2 is needed to achieve turning motion. When the robot gets the top of a specified target, the floating propeller 3 is closed to enable the robot dive. The locking motor is designed to make robot arms and fixed for the next step, high-pressure plunger pump is used to drive water hydraulic clean the jacket. After cleaning, the robot swim to other target as mentioned above and gradually completed all cleaning work. The recovery process of robot is shown as follow, clean off the pressure water gun, loose the robot from jacket, open up propeller 3 to make the robot above the surface of the water, open propeller 1 or 2 to make robot back to the initial position. Then, the whole mechanical control process ends.

Keywords: Aircraft drag parachute. Drag parachute pneumatic packing machine. The finite element analysis. The pneumatic control system

Abstract. As ground support equipment, drag parachute packing machine is used for packaging aircraft drag parachute. It is driven by high-pressure inert gas. Drag parachute will be compacted in the cylinder loading institution by high pressure. The overall structure of drag parachute packing machine is designed. The finite element analysis and structure optimization of drag parachute packing manipulator is completed. The pneumatic control system is designed. It provides an approach for drag parachute packing technology.

Introduction

By a drag parachute machine is meant a set of ground equipment used for packing the drag parachutes, so that the collection, storage and reuse of umbrella resistance could be made conveniently[1-3]. The current drag parachute machines mainly employ ball-screw and hydraulic type, both of which are large in volume, heavy in quality and not convenient to move. In order to overcome these problems, a new type of pneumatic umbrella packing machine is necessary.

Overall Structure of Drag Parachute Machine

Fig. 2 Mechanic Diagram of Packing Machine

Based on modular design, the pneumatic drag parachute machine adopts a simple structure, benefiting the daily maintenance and repairing of equipment. As shown in figure 1, three modules comprise the whole equipment, that is, mechanical module, the pressure and control module and human-computer interaction module[4-5].

As is shown in figure 2, the mechanical module is composed of loading umbrella racks, pressing instruments, mobile instruments and supporting instruments. By support institutions 1, we mean is the system used to support the supporting instrument, mount the loading umbrella racks, fix the mobile instrument and carry air pressure drive system, as well as to overcome the structural distortion from the pressure of work and turning torque. The pressing instrument, which is composed of the rocker arm 2, the air cylinder 4, and the compression plate 5, is responsible for compact the drag parachute, which is otherwise loose, tightly in the loading umbrella rack according to the requirement, in order to facilitate the transport and use. Large in size, the parachute, in order to be packed into the parachute bag, requires not only

A large pressure but also a strict sequence according to which the professional personnel pack the parachutes. For the convenience of packing the drag parachute in the racket, the pressing instrument is designed to rotate for 90 degrees horizontally with axis 3 as the center of rotation. In order to facilitate the job of worker, the air cylinder and pressing plate will rotate back to the position right upon the parachute racket when packing the parachutes. The compression parachute racket comprises a main and an auxiliary racket, with the former responsible for accommodating the inner racket when working. In order to facilitate the loading (or deloading) of the inner racket, an outward sliding door should be set outside the main racket. In this way, in order to load (deload) the inner racket, all we need to do is pull out (push in) the main racket. The mobile instrument 8 is designed as a mobile wheel. Driven by high-pressure gas, the new parachute machine, compared with the existing ones, is lighter, smaller and more convenient to operate. When the machine is required to be moved, what the worker needs to do is slant the whole packing machine by a certain degree with the clench of the handle and drag the packing machine to the destination.

Static Stress Analysis of Rocker Arm

The air cylinder works at the pressure of 4×10^{6}Pa. The cavity of the cylinder without rods boasts an effective area of $3.85\times10^{-3}m^{2}$, while the gas in the cylinder with rods emits in to the atmosphere directly. As a result, the counter pressure of the cylinder turns out null. Based on the settings above, it is easy to calculate that the working thrust of the cylinder is 15.4KN, a number signifying that the pressing instrument undertakes a giant deformation force when working. In order to ensure that the racket arm can sustain the deformation, it is desirable to perform an finite-element analysis upon the pressing instrument with SolidWorks Simulation and optimize the whole part structurally with the data obtained.

Topic of studies. By topic of studies is meant to decide which aspects of the pressing instrument to study. In this paper, we would perform static stress analysis upon the pressing instrument.

Material. The axis and the whole of the racket arm employs structural alloy steel while other parts apply ordinary steel.

Constraint. Constraint in the study includes fixture constraint and joint constraint.

Load. When the parachute is packed, it would exert upon the surface of pressing plate a reaction, of magnitude 15.4KN and upward in direction.

Calculate. Based on the settings above, the static stress analysis of the pressing instrument can be carried out.

Results analysis. Analyze the stress, deformation and displacement of the pressing instruments with SolidWorks Simulation. Fig. 3 illustrates the results, based on which we can tell the max stress σ of the racker arm is 292MPa and the yield limit of structural alloy steel equals 710MPa, that is, $\sigma = 292$MPa$<[\sigma_s] = 710$MPa. It could be easily seen that the stress runs behind the yield limit by far[4,5].

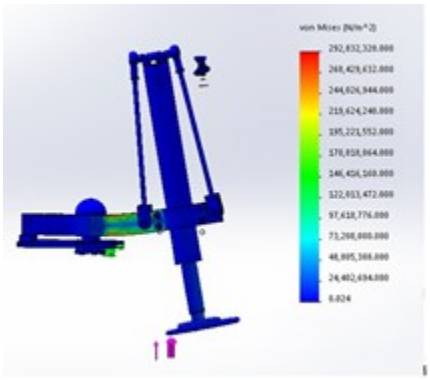

Fig. 3 Screenshot of Stress Analysis in Racker Arm

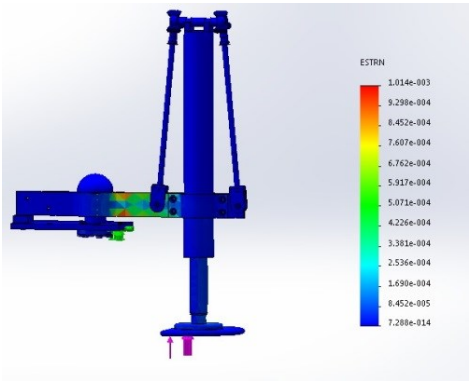

Fig. 4 Screenshot of Deformation Analysis in Racker Arm

Fig.4 illustrates the deformation of racket arm. Based on the data, the deformation ε equals1.01×10^{-3}, a magnitude small enough to be omitted.Fig. 5 illustrates the displacement of the air cylinder. Based on the data, the max displacement of the pressing instrument, of magnitude 3.28mm, occurs at the top the air cylinder, with the displacement of the pointed racket arm around 1.3mm.

Fig. 6 Pneumatic Schematic Diagram

Considering the high price of structural alloy steel, it is advisable substitute it with 45# normalized steel at 870°C in order to save money while meet the demand of pressing instruments. In order to test its feasibility, the data of the steel is listed in Table 1, with the comparison of those from structural alloy steel.

Table 1 Material parameter between before with after

Parameter / Material	Stress (MPa)	Deformation (10^{-003})	Displacement (mm)
alloy constructional steel	292	1.01	3.28
45#	292	0.99	3.28

Table 1 indicates an invisible change emerges after the material is altered. Though the safety factor and the yield limit surpass what is necessary by far when structural alloy steel is applied, it could, in another perspective, perceived as a waste of material and increase the expenditure. The analysis made by SolidWorks Simulation justifies the conclusion that the application of 45# normalize steel not only meets the demand but also lowers the cost.

Air-pressure Drive and Control System
